Full table of contents

1 Introduction	23
1.1 Where does this specification fit?	23
1.2 Is this HTML5?	23
1.3 Background	23
1.4 Audience	24
1.5 Scope	24
1.6 History	24
1.7 Design notes	25
1.7.1 Serialisability of script execution	25
1.7.2 Compliance with other specifications	26
1.7.3 Extensibility	26
1.8 HTML vs XHTML	26
1.9 Structure of this specification	27
1.9.1 How to read this specification	28
1.9.2 Typographic conventions	28
1.10 Privacy concerns	29
1.10.1 Cross-site communication	30
1.11 A quick introduction to HTML	30
1.11.1 Writing secure applications with HTML	32
1.11.2 Common pitfalls to avoid when using the scripting APIs	34
1.11.3 How to catch mistakes when writing HTML: validators and conformance checkers	34
1.12 Conformance requirements for authors	35
1.12.1 Presentational markup	35
1.12.2 Syntax errors	35
1.12.3 Restrictions on content models and on attribute values	38
1.13 Suggested reading	39

2 Common infrastructure	41
2.1 Terminology	41
2.1.1 Resources	41
2.1.2 XML	42
2.1.3 DOM trees	42
2.1.4 Scripting	43
2.1.5 Plugins	43
2.1.6 Character encodings	44
2.2 Conformance requirements	44
2.2.1 Conformance classes	45
2.2.2 Dependencies	47
2.2.3 Extensibility	55
2.2.4 Interactions with XPath and XSLT	57
2.3 Case-sensitivity and string comparison	58
2.4 Common microsyntaxes	58
2.4.1 Common parser idioms	58
2.4.2 Boolean attributes	59
2.4.3 Keywords and enumerated attributes	60
2.4.4 Numbers	60
2.4.4.1 Signed integers	60
2.4.4.2 Non-negative integers	61
2.4.4.3 Floating-point numbers	61
2.4.4.4 Percentages and lengths	63
2.4.4.5 Lists of integers	64
2.4.4.6 Lists of dimensions	65
2.4.5 Dates and times	66
2.4.5.1 Months	67
2.4.5.2 Dates	67
2.4.5.3 Yearless dates	68
2.4.5.4 Times	69
2.4.5.5 Local dates and times	70
2.4.5.6 Time zones	71
2.4.5.7 Global dates and times	72
2.4.5.8 Weeks	73
2.4.5.9 Durations	74
2.4.5.10 Vaguer moments in time	77
2.4.6 Colours	78
2.4.7 Space-separated tokens	80
2.4.8 Comma-separated tokens	80
2.4.9 References	81
2.4.10 Media queries	81
2.5 URLs	81
2.5.1 Terminology	81
2.5.2 Resolving URLs	82
2.5.3 Dynamic changes to base URLs	83
2.6 Fetching resources	83
2.6.1 Terminology	83
2.6.2 Processing model	84
2.6.3 Encrypted HTTP and related security concerns	86

2.6.4 Determining the type of a resource	86
2.6.5 Extracting character encodings from <code>meta</code> elements	86
2.6.6 CORS settings attributes	87
2.6.7 CORS-enabled fetch	87
2.7 Common DOM interfaces	88
2.7.1 Reflecting content attributes in IDL attributes	88
2.7.2 Collections	90
2.7.2.1 The <code>HTMLAllCollection</code> interface	90
2.7.2.2 The <code>HTMLFormControlsCollection</code> interface	91
2.7.2.3 The <code>HTMLOptionsCollection</code> interface	93
2.7.2.4 The <code>HTMLPropertiesCollection</code> interface	95
2.7.3 The <code>DOMStringMap</code> interface	96
2.7.4 <code>DOMElementMap</code>	97
2.7.5 Transferable objects	97
2.7.6 Safe passing of structured data	98
2.7.7 Callbacks	101
2.7.8 Garbage collection	101
2.8 Namespaces	101
3 Semantics, structure, and APIs of HTML documents	102
3.1 Documents	102
3.1.1 The <code>Document</code> object	102
3.1.2 Resource metadata management	103
3.1.3 DOM tree accessors	105
3.1.4 Loading XML documents	109
3.2 Elements	109
3.2.1 Semantics	109
3.2.2 Elements in the DOM	111
3.2.3 Element definitions	112
3.2.3.1 Attributes	113
3.2.4 Content models	113
3.2.4.1 The "nothing" content model	114
3.2.4.2 Kinds of content	114
3.2.4.2.1 Metadata content	115
3.2.4.2.2 Flow content	115
3.2.4.2.3 Sectioning content	116
3.2.4.2.4 Heading content	116
3.2.4.2.5 Phrasing content	116
3.2.4.2.6 Embedded content	116
3.2.4.2.7 Interactive content	116
3.2.4.2.8 Palpable content	117
3.2.4.2.9 Script-supporting elements	117
3.2.4.3 Transparent content models	117
3.2.4.4 Paragraphs	118
3.2.5 Global attributes	120
3.2.5.1 The <code>id</code> attribute	122
3.2.5.2 The <code>title</code> attribute	122
3.2.5.3 The <code>lang</code> and <code>xml:lang</code> attributes	123
3.2.5.4 The <code>translate</code> attribute	124
3.2.5.5 The <code>xml:base</code> attribute (XML only)	125

3.2.5.6 The <code>dir</code> attribute	125
3.2.5.7 The <code>class</code> attribute	128
3.2.5.8 The <code>style</code> attribute	128
3.2.5.9 Embedding custom non-visible data with the <code>data-*</code> attributes	128
3.2.6 Requirements relating to the bidirectional algorithm	131
3.2.6.1 Authoring conformance criteria for bidirectional-algorithm formatting characters	131
3.2.6.2 User agent conformance criteria	132
3.2.7 Annotations for assistive technology products (ARIA)	132
4 The elements of HTML	137
4.1 The root element	137
4.1.1 The <code>html</code> element	137
4.2 Document metadata	138
4.2.1 The <code>head</code> element	138
4.2.2 The <code>title</code> element	139
4.2.3 The <code>base</code> element	140
4.2.4 The <code>link</code> element	141
4.2.5 The <code>meta</code> element	145
4.2.5.1 Standard metadata names	147
4.2.5.2 Other metadata names	148
4.2.5.3 Pragma directives	149
4.2.5.4 Other pragma directives	152
4.2.5.5 Specifying the document's character encoding	153
4.2.6 The <code>style</code> element	154
4.2.7 Interactions of styling and scripting	157
4.3 Sections	157
4.3.1 The <code>body</code> element	157
4.3.2 The <code>article</code> element	159
4.3.3 The <code>section</code> element	161
4.3.4 The <code>nav</code> element	163
4.3.5 The <code>aside</code> element	166
4.3.6 The <code>h1, h2, h3, h4, h5, and h6</code> elements	168
4.3.7 The <code>hgroup</code> element	170
4.3.8 The <code>header</code> element	171
4.3.9 The <code>footer</code> element	173
4.3.10 The <code>address</code> element	175
4.3.11 Headings and sections	176
4.3.11.1 Creating an outline	178
4.3.11.2 Sample outlines	181
4.3.11.3 Exposing outlines to users	185
4.3.12 Usage summary	186
4.3.12.1 Article or section?	187
4.4 Grouping content	187
4.4.1 The <code>p</code> element	187
4.4.2 The <code>hr</code> element	190
4.4.3 The <code>pre</code> element	191
4.4.4 The <code>blockquote</code> element	193
4.4.5 The <code>ol</code> element	195

4.4.6 The <code>u1</code> element	197
4.4.7 The <code>li</code> element	198
4.4.8 The <code>dl</code> element	199
4.4.9 The <code>dt</code> element	201
4.4.10 The <code>dd</code> element	202
4.4.11 The <code>figure</code> element	202
4.4.12 The <code>figcaption</code> element	205
4.4.13 The <code>main</code> element	205
4.4.14 The <code>div</code> element	207
4.5 Text-level semantics	208
4.5.1 The <code>a</code> element	208
4.5.2 The <code>em</code> element	210
4.5.3 The <code>strong</code> element	211
4.5.4 The <code>small</code> element	212
4.5.5 The <code>s</code> element	214
4.5.6 The <code>cite</code> element	214
4.5.7 The <code>a</code> element	215
4.5.8 The <code>dfn</code> element	217
4.5.9 The <code>abbr</code> element	218
4.5.10 The <code>ruby</code> element	219
4.5.11 The <code>rt</code> element	225
4.5.12 The <code>rp</code> element	225
4.5.13 The <code>data</code> element	226
4.5.14 The <code>time</code> element	227
4.5.15 The <code>code</code> element	231
4.5.16 The <code>var</code> element	232
4.5.17 The <code>samp</code> element	233
4.5.18 The <code>kbd</code> element	234
4.5.19 The <code>sub</code> and <code>sup</code> elements	235
4.5.20 The <code>i</code> element	235
4.5.21 The <code>b</code> element	236
4.5.22 The <code>u</code> element	237
4.5.23 The <code>mark</code> element	238
4.5.24 The <code>bdi</code> element	240
4.5.25 The <code>bdo</code> element	241
4.5.26 The <code>span</code> element	242
4.5.27 The <code>br</code> element	242
4.5.28 The <code>wbr</code> element	243
4.5.29 Usage summary	244
4.6 Links	245
4.6.1 Introduction	245
4.6.2 Links created by <code>a</code> and <code>area</code> elements	245
4.6.3 Following hyperlinks	246
4.6.4 Downloading resources	247
4.6.4.1 Hyperlink auditing	249
4.6.5 Link types	250

4.6.5.1 Link type "alternate"	250
4.6.5.2 Link type "author"	251
4.6.5.3 Link type "bookmark"	252
4.6.5.4 Link type "external"	252
4.6.5.5 Link type "help"	252
4.6.5.6 Link type "icon"	253
4.6.5.7 Link type "license"	254
4.6.5.8 Link type "nofollow"	255
4.6.5.9 Link type "noreferrer"	255
4.6.5.10 Link type "pingback"	255
4.6.5.11 Link type "prefetch"	255
4.6.5.12 Link type "search"	256
4.6.5.13 Link type "sidebar"	256
4.6.5.14 Link type "stylesheet"	256
4.6.5.15 Link type "tag"	257
4.6.5.16 Sequential link types	258
4.6.5.16.1 Link type "next"	259
4.6.5.16.2 Link type "prev"	259
4.6.5.17 Other link types	259
 4.7 Edits	260
4.7.1 The <code>ins</code> element	260
4.7.2 The <code>del</code> element	262
4.7.3 Attributes common to <code>ins</code> and <code>del</code> elements	262
4.7.4 Edits and paragraphs	263
4.7.5 Edits and lists	264
4.7.6 Edits and tables	264
 4.8 Embedded content	265
4.8.1 Introduction	265
4.8.1.1 Adaptive images	268
4.8.1.2 Dependencies	270
4.8.1.3 The <code>picture</code> element	270
4.8.1.4 The <code>source</code> element when used with the <code>picture</code> element	271
4.8.1.5 The <code>img</code> element	272
4.8.5.1 Requirements for providing text to act as an alternative for images	288
4.8.5.1.1 General guidelines	288
4.8.5.1.2 A link or button containing nothing but the image	288
4.8.5.1.3 A phrase or paragraph with an alternative graphical representation: charts, diagrams, graphs, maps, illustrations	289
4.8.5.1.4 A short phrase or label with an alternative graphical representation: icons, logos	290
4.8.5.1.5 Text that has been rendered to a graphic for typographical effect	291
4.8.5.1.6 A graphical representation of some of the surrounding text	292
4.8.5.1.7 Ancillary images	293
4.8.5.1.8 A purely decorative image that doesn't add any information	294
4.8.5.1.9 A group of images that form a single larger picture with no links	294
4.8.5.1.10 A group of images that form a single larger picture with links	295
4.8.5.1.11 A key part of the content	295
4.8.5.1.12 An image not intended for the user	298
4.8.5.1.13 An image in an e-mail or private document intended for a specific person who is known to be able to view images	298
4.8.5.1.14 Guidance for markup generators	298
4.8.5.1.15 Guidance for conformance checkers	299

4.8.6 The <code>iframe</code> element.....	299
4.8.7 The <code>embed</code> element.....	307
4.8.8 The <code>object</code> element.....	310
4.8.9 The <code>param</code> element.....	316
4.8.10 The <code>video</code> element.....	317
4.8.11 The <code>audio</code> element.....	321
4.8.12 The <code>source</code> element.....	322
4.8.13 The <code>track</code> element.....	324
4.8.14 Media elements	326
4.8.14.1 Error codes.....	328
4.8.14.2 Location of the media resource	329
4.8.14.3 MIME types.....	329
4.8.14.4 Network states.....	331
4.8.14.5 Loading the media resource	331
4.8.14.6 Offsets into the media resource	340
4.8.14.7 Ready states	343
4.8.14.8 Playing the media resource	345
4.8.14.9 Seeking	351
4.8.14.10 Media resources with multiple media tracks.....	353
4.8.14.10.1 <code>AudioTrackList</code> and <code>VideoTrackList</code> objects.....	354
4.8.14.10.2 Selecting specific audio and video tracks declaratively.....	357
4.8.14.11 Synchronising multiple media elements	358
4.8.14.11.1 Introduction.....	358
4.8.14.11.2 Media controllers	358
4.8.14.11.3 Assigning a media controller declaratively	364
4.8.14.12 Timed text tracks	365
4.8.14.12.1 Text track model	365
4.8.14.12.2 Sourcing in-band text tracks	369
4.8.14.12.3 Sourcing out-of-band text tracks	370
4.8.14.12.4 Guidelines for exposing cues in various formats as text track cues	373
4.8.14.12.5 Text track API	373
4.8.14.12.6 Text tracks describing chapters	379
4.8.14.12.7 Event handlers for objects of the text track APIs	380
4.8.14.12.8 Best practices for metadata text tracks	380
4.8.14.13 User interface	382
4.8.14.14 Time ranges	384
4.8.14.15 The <code>TrackEvent</code> interface	385
4.8.14.16 Event summary.....	385
4.8.14.17 Security and privacy considerations	388
4.8.14.18 Best practices for authors using media elements	388
4.8.14.19 Best practices for implementors of media elements	388
4.8.15 The <code>map</code> element	389
4.8.16 The <code>area</code> element.....	390
4.8.17 Image maps.....	393
4.8.17.1 Authoring	393
4.8.17.2 Processing model	393
4.8.18 MathML	395
4.8.19 SVG	396
4.8.20 Dimension attributes	397
4.9 Tabular data	398
4.9.1 The <code>table</code> element.....	398
4.9.1.1 Techniques for describing tables.....	402

4.9.1.2 Techniques for table design	405
4.9.2 The <code>caption</code> element	405
4.9.3 The <code>colgroup</code> element	406
4.9.4 The <code>col</code> element	407
4.9.5 The <code>tbody</code> element	408
4.9.6 The <code>thead</code> element	409
4.9.7 The <code>tfoot</code> element	410
4.9.8 The <code>tr</code> element	411
4.9.9 The <code>td</code> element	412
4.9.10 The <code>th</code> element	414
4.9.11 Attributes common to <code>td</code> and <code>th</code> elements	416
4.9.12 Processing model	417
4.9.12.1 Forming a table	418
4.9.12.2 Forming relationships between data cells and header cells	421
4.9.13 Table sorting model	422
4.9.14 Examples	435
4.10 Forms	438
4.10.1 Introduction	438
4.10.1.1 Writing a form's user interface	439
4.10.1.2 Implementing the server-side processing for a form	441
4.10.1.3 Configuring a form to communicate with a server	441
4.10.1.4 Client-side form validation	442
4.10.1.5 Enabling client-side automatic filling of form controls	444
4.10.1.6 Improving the user experience on mobile devices	444
4.10.1.7 The difference between the field type, the autofocus field name, and the input modality	445
4.10.1.8 Date, time, and number formats	446
4.10.2 Categories	446
4.10.3 The <code>form</code> element	447
4.10.4 The <code>label</code> element	451
4.10.5 The <code>input</code> element	452
4.10.5.1 States of the <code>type</code> attribute	458
4.10.5.1.1 Hidden state (<code>type=hidden</code>)	458
4.10.5.1.2 Text (<code>type=text</code>) state and Search state (<code>type=search</code>)	458
4.10.5.1.3 Telephone state (<code>type=tel</code>)	459
4.10.5.1.4 URL state (<code>type=url</code>)	460
4.10.5.1.5 E-mail state (<code>type=email</code>)	461
4.10.5.1.6 Password state (<code>type=password</code>)	462
4.10.5.1.7 Date and Time state (<code>type=datetime</code>)	463
4.10.5.1.8 Date state (<code>type=date</code>)	464
4.10.5.1.9 Month state (<code>type=month</code>)	465
4.10.5.1.10 Week state (<code>type=week</code>)	466
4.10.5.1.11 Time state (<code>type=time</code>)	467
4.10.5.1.12 Local Date and Time state (<code>type=datetime-local</code>)	468
4.10.5.1.13 Number state (<code>type=number</code>)	469
4.10.5.1.14 Range state (<code>type=range</code>)	470
4.10.5.1.15 Colour state (<code>type=color</code>)	474
4.10.5.1.16 Checkbox state (<code>type=checkbox</code>)	475
4.10.5.1.17 Radio Button state (<code>type=radio</code>)	475
4.10.5.1.18 File Upload state (<code>type=file</code>)	476
4.10.5.1.19 Submit Button state (<code>type=submit</code>)	478
4.10.5.1.20 Image Button state (<code>type=image</code>)	479

4.10.5.1.21 Reset Button state (<code>type=reset</code>)	481
4.10.5.1.22 Button state (<code>type=button</code>)	482
4.10.5.2 Implementation notes regarding localization of form controls	482
4.10.5.3 Common <code>input</code> element attributes	482
4.10.5.3.1 The <code>maxlength</code> and <code>minlength</code> attributes	483
4.10.5.3.2 The <code>size</code> attribute	483
4.10.5.3.3 The <code>readonly</code> attribute	483
4.10.5.3.4 The <code>required</code> attribute	484
4.10.5.3.5 The <code>multiple</code> attribute	485
4.10.5.3.6 The <code>pattern</code> attribute	486
4.10.5.3.7 The <code>min</code> and <code>max</code> attributes	486
4.10.5.3.8 The <code>step</code> attribute	488
4.10.5.3.9 The <code>list</code> attribute	489
4.10.5.3.10 The <code>placeholder</code> attribute	490
4.10.5.4 Common <code>input</code> element APIs	491
4.10.5.5 Common event behaviours	494
4.10.6 The <code>button</code> element	495
4.10.7 The <code>select</code> element	498
4.10.8 The <code>datalist</code> element	503
4.10.9 The <code>optgroup</code> element	504
4.10.10 The <code>option</code> element	505
4.10.11 The <code>textarea</code> element	508
4.10.12 The <code>keygen</code> element	513
4.10.13 The <code>output</code> element	516
4.10.14 The <code>progress</code> element	518
4.10.15 The <code>meter</code> element	519
4.10.16 The <code>fieldset</code> element	524
4.10.17 The <code>legend</code> element	526
4.10.18 Form control infrastructure	527
4.10.18.1 A form control's value	527
4.10.18.2 Mutability	527
4.10.18.3 Association of controls and forms	527
4.10.19 Attributes common to form controls	529
4.10.19.1 Naming form controls: the <code>name</code> attribute	529
4.10.19.2 Submitting element directionality: the <code>dirname</code> attribute	529
4.10.19.3 Limiting user input length: the <code>maxlength</code> attribute	529
4.10.19.4 Setting minimum input length requirements: the <code>minlength</code> attribute	530
4.10.19.5 Enabling and disabling form controls: the <code>disabled</code> attribute	530
4.10.19.6 Form submission	531
4.10.19.6.1 Autofocusing a form control: the <code>autofocus</code> attribute	533
4.10.19.7 Input modalities: the <code>inputmode</code> attribute	534
4.10.19.8 Autocomplete	535
4.10.19.8.1 Autocompleting form controls: the <code>autocomplete</code> attribute	535
4.10.19.8.2 Processing model	540
4.10.19.8.3 User interface for bulk autocomplete	547
4.10.19.8.4 The <code>AutocompleteErrorEvent</code> interface	548
4.10.20 APIs for the text field selections	549
4.10.21 Constraints	553
4.10.21.1 Definitions	553
4.10.21.2 Constraint validation	554
4.10.21.3 The constraint validation API	554

4.10.21.4 Security	557
4.10.22 Form submission	557
4.10.22.1 Introduction	557
4.10.22.2 Implicit submission	558
4.10.22.3 Form submission algorithm	558
4.10.22.4 Constructing the form data set	561
4.10.22.5 Selecting a form submission encoding	563
4.10.22.6 URL-encoded form data	563
4.10.22.7 Multipart form data	565
4.10.22.8 Plain text form data	566
4.10.23 Resetting a form	567
4.11 Interactive elements	567
4.11.1 The <code>details</code> element	567
4.11.2 The <code>summary</code> element	571
4.11.3 The <code>menu</code> element	571
4.11.4 The <code>menuitem</code> element	574
4.11.5 Context menus	577
4.11.5.1 Declaring a context menu	577
4.11.5.2 Processing model	577
4.11.5.3 The <code>RelatedEvent</code> interfaces	579
4.11.6 Commands	579
4.11.6.1 Facets	579
4.11.6.2 Using the <code>a</code> element to define a command	581
4.11.6.3 Using the <code>button</code> element to define a command	582
4.11.6.4 Using the <code>input</code> element to define a command	582
4.11.6.5 Using the <code>option</code> element to define a command	583
4.11.6.6 Using the <code>menuitem</code> element to define a command	583
4.11.6.7 Using the <code>command</code> attribute on <code>menuitem</code> elements to define a command indirectly	584
4.11.6.8 Using the <code>accesskey</code> attribute on a <code>label</code> element to define a command	584
4.11.6.9 Using the <code>accesskey</code> attribute on a <code>legend</code> element to define a command	585
4.11.6.10 Using the <code>accesskey</code> attribute to define a command on other elements	585
4.11.7 The <code>dialog</code> element	586
4.11.7.1 Anchor points	591
4.12 Scripting	591
4.12.1 The <code>script</code> element	591
4.12.1.1 Scripting languages	599
4.12.1.2 Restrictions for contents of <code>script</code> elements	599
4.12.1.3 Inline documentation for external scripts	601
4.12.1.4 Interaction of <code>script</code> elements and XSLT	602
4.12.2 The <code>noscript</code> element	602
4.12.3 The <code>template</code> element	604
4.12.3.1 Interaction of <code>template</code> elements with XSLT and XPath	607
4.12.4 The <code>canvas</code> element	607
4.12.4.1 Proxying canvases to workers	611
4.12.4.2 The 2D rendering context	613
4.12.4.2.1 Implementation notes	621
4.12.4.2.2 The canvas state	621
4.12.4.2.3 <code>DrawingStyle</code> objects	622
4.12.4.2.4 Line styles	622
4.12.4.2.5 Text styles	626
4.12.4.2.6 Building paths	630

4.12.4.2.7 <code>Path2D</code> objects	634
4.12.4.2.8 Transformations	638
4.12.4.2.9 Image sources for 2D rendering contexts	640
4.12.4.2.10 Fill and stroke styles	641
4.12.4.2.11 Drawing rectangles to the bitmap	644
4.12.4.2.12 Drawing text to the bitmap	645
4.12.4.2.13 Drawing paths to the canvas	647
4.12.4.2.14 Drawing images	651
4.12.4.2.15 Hit regions	652
4.12.4.2.16 Pixel manipulation	659
4.12.4.2.17 Compositing	663
4.12.4.2.18 Image smoothing	663
4.12.4.2.19 Shadows	663
4.12.4.2.20 Drawing model	665
4.12.4.2.21 Best practices	665
4.12.4.2.22 Examples	666
4.12.4.3 Colour spaces and colour correction	670
4.12.4.4 Serialising bitmaps to a file	670
4.12.4.5 Security with <code>canvas</code> elements	671
4.13 Common idioms without dedicated elements	671
4.13.1 The main part of the content	671
4.13.2 Bread crumb navigation	673
4.13.3 Tag clouds	674
4.13.4 Conversations	674
4.13.5 Footnotes	677
4.14 Disabled elements	678
4.15 Matching HTML elements using selectors	679
4.15.1 Case-sensitivity	679
4.15.2 Pseudo-classes	679
 5 Microdata	683
5.1 Introduction	683
5.1.1 Overview	683
5.1.2 The basic syntax	683
5.1.3 Typed items	686
5.1.4 Global identifiers for items	686
5.1.5 Selecting names when defining vocabularies	687
5.1.6 Using the microdata DOM API	687
5.2 Encoding microdata	689
5.2.1 The microdata model	689
5.2.2 Items	689
5.2.3 Names: the <code>itemprop</code> attribute	692
5.2.4 Values	693
5.2.5 Associating names with items	694
5.2.6 Microdata and other namespaces	695
5.3 Microdata DOM API	695
5.4 Sample microdata vocabularies	697
5.4.1 vCard	697
5.4.1.1 Conversion to vCard	706
5.4.1.2 Examples	710
5.4.2 vEvent	711

5.4.2.1 Conversion to iCalendar	716
5.4.2.2 Examples.....	717
5.4.3 Licensing works	719
5.4.3.1 Examples.....	719
5.5 Converting HTML to other formats	720
5.5.1 JSON.....	720
 6 User interaction	723
6.1 The <code>hidden</code> attribute	723
6.2 Inert subtrees	724
6.3 Activation.....	724
6.4 Focus.....	725
6.4.1 Introduction.....	725
6.4.2 Data model	726
6.4.3 The <code>tabindex</code> attribute	729
6.4.4 Processing model.....	730
6.4.5 Sequential focus navigation	734
6.4.6 Focus management APIs	735
6.5 Assigning keyboard shortcuts	737
6.5.1 Introduction.....	737
6.5.2 The <code>accesskey</code> attribute	738
6.5.3 Processing model.....	739
6.6 Editing.....	739
6.6.1 Making document regions editable: The <code>contenteditable</code> content attribute	739
6.6.2 Making entire documents editable: The <code>designMode</code> IDL attribute	740
6.6.3 Best practices for in-page editors	740
6.6.4 Editing APIs	741
6.6.5 Spelling and grammar checking.....	741
6.7 Drag and drop	743
6.7.1 Introduction.....	743
6.7.2 The <code>drag</code> data store	745
6.7.3 The <code>DataTransfer</code> interface	746
6.7.3.1 The <code>DataTransferItemList</code> interface	748
6.7.3.2 The <code>DataTransferItem</code> interface	750
6.7.4 The <code>DragEvent</code> interface	751
6.7.5 Drag-and-drop processing model.....	753
6.7.6 Events summary.....	758
6.7.7 The <code>draggable</code> attribute	758
6.7.8 The <code>dropzone</code> attribute	759
6.7.9 Security risks in the drag-and-drop model.....	760
 7 Loading Web pages	762
7.1 Browsing contexts	762
7.1.1 Nested browsing contexts	763
7.1.1.1 Navigating nested browsing contexts in the DOM.....	763
7.1.2 Auxiliary browsing contexts	764
7.1.2.1 Navigating auxiliary browsing contexts in the DOM	764

7.1.3 Secondary browsing contexts	764
7.1.4 Security	764
7.1.5 Groupings of browsing contexts	765
7.1.6 Browsing context names	765
7.2 The <code>Window</code> object	768
7.2.1 Security	769
7.2.2 APIs for creating and navigating browsing contexts by name	770
7.2.3 Accessing other browsing contexts	772
7.2.4 Named access on the <code>Window</code> object	772
7.2.5 Garbage collection and browsing contexts	773
7.2.6 Closing browsing contexts	774
7.2.7 Browser interface elements	774
7.2.8 The <code>WindowProxy</code> object	775
7.3 Origin	776
7.3.1 Relaxing the same-origin restriction	778
7.4 Sandboxing	780
7.5 Session history and navigation	782
7.5.1 The session history of browsing contexts	782
7.5.2 The <code>History</code> interface	783
7.5.3 The <code>Location</code> interface	788
7.5.3.1 Security	790
7.5.4 Implementation notes for session history	790
7.6 Browsing the Web	791
7.6.1 Navigating across documents	791
7.6.2 Page load processing model for HTML files	797
7.6.3 Page load processing model for XML files	797
7.6.4 Page load processing model for text files	798
7.6.5 Page load processing model for <code>multipart/x-mixed-replace</code> resources	798
7.6.6 Page load processing model for media	799
7.6.7 Page load processing model for content that uses plugins	799
7.6.8 Page load processing model for inline content that doesn't have a DOM	799
7.6.9 Navigating to a fragment identifier	800
7.6.10 History traversal	801
7.6.10.1 The <code>PopStateEvent</code> interface	803
7.6.10.2 The <code>HashChangeEvent</code> interface	803
7.6.10.3 The <code>PageTransitionEvent</code> interface	803
7.6.11 Unloading documents	804
7.6.11.1 The <code>BeforeUnloadEvent</code> interface	806
7.6.12 Aborting a document load	806
7.7 Offline Web applications	806
7.7.1 Introduction	806
7.7.1.1 Supporting offline caching for legacy applications	807
7.7.1.2 Event summary	808
7.7.2 Application caches	809
7.7.3 The cache manifest syntax	810
7.7.3.1 Some sample manifests	810
7.7.3.2 Writing cache manifests	812
7.7.3.3 Parsing cache manifests	813

7.7.4 Downloading or updating an application cache	816
7.7.5 The application cache selection algorithm	822
7.7.6 Changes to the networking model	823
7.7.7 Expiring application caches	823
7.7.8 Disk space	824
7.7.9 Security concerns with offline applications caches	824
7.7.10 Application cache API	824
7.7.11 Browser state	827
8 Web application APIs	828
8.1 Scripting	828
 8.1.1 Introduction	828
 8.1.2 Enabling and disabling scripting	828
 8.1.3 Processing model	828
 8.1.3.1 Definitions	828
 8.1.3.2 Script settings for browsing contexts	830
 8.1.3.3 Calling scripts	830
 8.1.3.4 Creating scripts	832
 8.1.3.5 Killing scripts	832
 8.1.3.6 Runtime script errors	833
 8.1.3.6.1 Runtime script errors in documents	833
 8.1.3.6.2 The <code>ErrorEvent</code> interface	834
 8.1.4 Event loops	834
 8.1.4.1 Definitions	834
 8.1.4.2 Processing model	835
 8.1.4.3 Generic task sources	838
 8.1.5 Events	839
 8.1.5.1 Event handlers	839
 8.1.5.2 Event handlers on elements, <code>Document</code> objects, and <code>Window</code> objects	843
 8.1.5.2.1 IDL definitions	845
 8.1.5.3 Event firing	846
 8.1.5.4 Events and the <code>window</code> object	846
 8.2 Base64 utility methods	847
 8.3 Dynamic markup insertion	848
 8.3.1 Opening the input stream	848
 8.3.2 Closing the input stream	850
 8.3.3 <code>document.write()</code>	850
 8.3.4 <code>document.writeln()</code>	851
 8.4 Timers	852
 8.5 User prompts	854
 8.5.1 Simple dialogs	854
 8.5.2 Printing	855
 8.5.3 Dialogs implemented using separate documents with <code>showModalDialog()</code>	856
 8.6 System state and capabilities	858
 8.6.1 The <code>Navigator</code> object	858
 8.6.1.1 Client identification	859
 8.6.1.2 Language preferences	860
 8.6.1.3 Custom scheme and content handlers: the <code>registerProtocolHandler()</code> and <code>registerContentHandler()</code> methods	861
 8.6.1.3.1 Security and privacy	865

8.6.1.3.2 Sample user interface	866
8.6.1.4 Manually releasing the storage mutex	868
8.6.1.5 Plugins	868
8.6.2 The <code>External</code> interface	873
8.7 Images	874
8.8 Animation Frames	878
9 Communication	880
9.1 The <code>MessageEvent</code> interfaces	880
9.2 Server-sent events	881
9.2.1 Introduction	881
9.2.2 The <code>EventSource</code> interface	882
9.2.3 Processing model	883
9.2.4 Parsing an event stream	885
9.2.5 Interpreting an event stream	885
9.2.6 Authoring notes	888
9.2.7 Connectionless push and other features	888
9.2.8 Garbage collection	889
9.2.9 Implementation advice	889
9.2.10 IANA considerations	889
9.2.10.1 <code>text/event-stream</code>	889
9.2.10.2 <code>Last-Event-ID</code>	890
9.3 Web sockets	891
9.3.1 Introduction	891
9.3.2 The <code>WebSocket</code> interface	891
9.3.3 Feedback from the protocol	895
9.3.4 Ping and Pong frames	897
9.3.5 Parsing WebSocket URLs	897
9.3.6 The <code>closeEvent</code> interfaces	897
9.3.7 Garbage collection	898
9.4 Cross-document messaging	898
9.4.1 Introduction	899
9.4.2 Security	899
9.4.2.1 Authors	899
9.4.2.2 User agents	899
9.4.3 Posting messages	900
9.5 Channel messaging	901
9.5.1 Introduction	901
9.5.1.1 Examples	901
9.5.1.2 Ports as the basis of an object-capability model on the Web	902
9.5.1.3 Ports as the basis of abstracting out service implementations	903
9.5.2 Message channels	903
9.5.3 Message ports	904
9.5.4 Broadcasting to many ports	907
9.5.5 Ports and garbage collection	908
9.6 Broadcasting to other browsing contexts	908
10 Web workers	911

10.1 Introduction	911
10.1.1 Scope	911
10.1.2 Examples	911
10.1.2.1 A background number-crunching worker	911
10.1.2.2 Worker used for background I/O	912
10.1.2.3 Shared workers introduction	914
10.1.2.4 Shared state using a shared worker	915
10.1.2.5 Delegation	920
10.1.3 Tutorials	921
10.1.3.1 Creating a dedicated worker	921
10.1.3.2 Communicating with a dedicated worker	922
10.1.3.3 Shared workers	922
10.2 Infrastructure	923
10.2.1 The global scope	923
10.2.1.1 The <code>WorkerGlobalScope</code> common interface	923
10.2.1.2 Dedicated workers and the <code>DedicatedWorkerGlobalScope</code> interface	924
10.2.1.3 Shared workers and the <code>SharedWorkerGlobalScope</code> interface	924
10.2.2 The event loop	925
10.2.3 The worker's lifetime	925
10.2.4 Processing model	926
10.2.5 Runtime script errors	927
10.2.6 Creating workers	928
10.2.6.1 The <code>AbstractWorker</code> abstract interface	928
10.2.6.2 Script settings for workers	928
10.2.6.3 Dedicated workers and the <code>Worker</code> interface	929
10.2.6.4 Shared workers and the <code>SharedWorker</code> interface	930
10.3 APIs available to workers	932
10.3.1 Importing scripts and libraries	932
10.3.2 The <code>WorkerNavigator</code> object	933
10.3.3 Worker locations	933
11 Web storage	934
11.1 Introduction	934
11.2 The API	935
11.2.1 The <code>Storage</code> interface	935
11.2.2 The <code>sessionStorage</code> attribute	936
11.2.3 The <code>localStorage</code> attribute	936
11.2.4 The <code>storage</code> event	937
11.2.4.1 The <code>StorageEvent</code> interface	937
11.2.5 Threads	938
11.3 Disk space	938
11.4 Privacy	939
11.4.1 User tracking	939
11.4.2 Sensitivity of data	940
11.5 Security	940
11.5.1 DNS spoofing attacks	940
11.5.2 Cross-directory attacks	940
11.5.3 Implementation risks	940

12 The HTML syntax	941
12.1 Writing HTML documents	941
12.1.1 The DOCTYPE	941
12.1.2 Elements	942
12.1.2.1 Start tags	944
12.1.2.2 End tags	944
12.1.2.3 Attributes	944
12.1.2.4 Optional tags	946
12.1.2.5 Restrictions on content models	950
12.1.2.6 Restrictions on the contents of raw text and escapable raw text elements	951
12.1.3 Text	951
12.1.3.1 Newlines	951
12.1.4 Character references	951
12.1.5 CDATA sections	952
12.1.6 Comments	952
12.2 Parsing HTML documents	952
12.2.1 Overview of the parsing model	954
12.2.2 The input byte stream	954
12.2.2.1 Parsing with a known character encoding	955
12.2.2.2 Determining the character encoding	955
12.2.2.3 Character encodings	960
12.2.2.4 Changing the encoding while parsing	960
12.2.2.5 Preprocessing the input stream	960
12.2.3 Parse state	961
12.2.3.1 The insertion mode	961
12.2.3.2 The stack of open elements	962
12.2.3.3 The list of active formatting elements	964
12.2.3.4 The element pointers	965
12.2.3.5 Other parsing state flags	965
12.2.4 Tokenization	965

1 Introduction

Spec bugs: [23036](#)

1.1 Where does this specification fit?

This specification defines a big part of the Web platform, in lots of detail. Its place in the Web platform specification stack relative to other specifications can be best summed up as follows:

1.2 Is this HTML5?

This section is non-normative.

In short: Yes.

In more length: The term "HTML5" is widely used as a buzzword to refer to modern Web technologies, many of which (though by no means all) are developed at the WHATWG. This document is one such; others are available from [the WHATWG specification index](#).

Note *Although we have asked them to stop doing so, the W3C also republishes some parts of this specification as separate documents. There are numerous differences between this specification and the W3C forks; some minor, some major. Unfortunately these are not currently accurately documented anywhere, so there is no way to know which are intentional and which are not.*

1.3 Background

This section is non-normative.

HTML is the World Wide Web's core markup language. Originally, HTML was primarily designed as a language for semantically describing scientific documents. Its general design, however, has enabled it to be adapted, over the subsequent years, to describe a number of other types of documents and even applications.

1.4 Audience

This section is non-normative.

This specification is intended for authors of documents and scripts that use the features defined in this specification, implementors of tools that operate on pages that use the features defined in this specification, and individuals wishing to establish the correctness of documents or implementations with respect to the requirements of this specification.

This document is probably not suited to readers who do not already have at least a passing familiarity with Web technologies, as in places it sacrifices clarity for precision, and brevity for completeness. More approachable tutorials and authoring guides can provide a gentler introduction to the topic.

In particular, familiarity with the basics of DOM is necessary for a complete understanding of some of the more technical parts of this specification. An understanding of Web IDL, HTTP, XML, Unicode, character encodings, JavaScript, and CSS will also be helpful in places but is not essential.

1.5 Scope

This section is non-normative.

This specification is limited to providing a semantic-level markup language and associated semantic-level scripting APIs for authoring accessible pages on the Web ranging from static documents to dynamic applications.

The scope of this specification does not include providing mechanisms for media-specific customization of presentation (although default rendering rules for Web browsers are included at the end of this specification, and several mechanisms for hooking into CSS are provided as part of the language).

The scope of this specification is not to describe an entire operating system. In particular, hardware configuration software, image manipulation tools, and applications that users would be expected to use with high-end workstations on a daily basis are out of scope. In terms of applications, this specification is targeted specifically at applications that would be expected to be used by users on an occasional basis, or regularly but from disparate locations, with low CPU requirements. Examples of such applications include online purchasing systems, searching systems, games (especially multiplayer online games), public telephone books or address books, communications software (e-mail clients, instant messaging clients, discussion software), document editing software, etc.

1.6 History

Spec bugs: [27500](#)

This section is non-normative.

For its first five years (1990-1995), HTML went through a number of revisions and experienced a number of extensions, primarily hosted first at CERN, and then at the IETF.

With the creation of the W3C, HTML's development changed venue again. A first abortive attempt at extending HTML in 1995 known as HTML 3.0 then made way to a more pragmatic approach known as HTML 3.2, which was completed in 1997. HTML4 quickly followed later that same year.

The following year, the W3C membership decided to stop evolving HTML and instead begin work on an XML-based equivalent, called XHTML. This effort started with a reformulation of HTML4 in XML, known as XHTML 1.0, which added no new features except the new serialisation, and which was completed in 2000. After XHTML 1.0, the W3C's focus turned to making it easier for other working groups to extend XHTML, under the banner of XHTML Modularization. In parallel with this, the W3C also worked on a new language that was not compatible with the earlier HTML and XHTML languages, calling it XHTML2.

Around the time that HTML's evolution was stopped in 1998, parts of the API for HTML developed by browser vendors were specified and published under the name DOM Level 1 (in 1998) and DOM Level 2 Core and DOM Level 2 HTML (starting in 2000 and culminating in 2003). These efforts then petered out, with some DOM Level 3 specifications published in 2004 but the working group being closed before all the Level 3 drafts were completed.

In 2003, the publication of XForms, a technology which was positioned as the next generation of Web forms, sparked a renewed interest in evolving HTML itself, rather than finding replacements for it. This interest was borne from the realization that XML's deployment as a Web technology was limited to entirely new technologies (like RSS and later Atom), rather than as a replacement for existing deployed technologies (like HTML).

A proof of concept to show that it was possible to extend HTML4's forms to provide many of the features that XForms 1.0 introduced, without requiring browsers to implement rendering engines that were incompatible with existing HTML Web pages, was the first result of this renewed interest. At this early stage, while the draft was already publicly available, and input was already being solicited from all sources, the specification was only under Opera Software's copyright.

The idea that HTML's evolution should be reopened was tested at a W3C workshop in 2004, where some of the principles that underlie the HTML5 work (described below), as well as the aforementioned early draft proposal covering just forms-related features, were presented to the W3C jointly by Mozilla and Opera. The proposal was rejected on the grounds that the proposal conflicted with the previously chosen direction for the Web's evolution; the W3C staff and membership voted to continue developing XML-based replacements instead.

Shortly thereafter, Apple, Mozilla, and Opera jointly announced their intent to continue working on the effort under the umbrella of a new venue called the WHATWG. A public mailing list was created, and the draft was moved to the WHATWG site. The copyright was subsequently amended to be jointly owned by all three vendors, and to allow reuse of the specification.

The WHATWG was based on several core principles, in particular that technologies need to be backwards compatible, that specifications and implementations need to match even if this means changing the specification rather than the implementations, and that specifications need to be detailed enough that implementations can achieve complete interoperability without reverse-engineering each other.

The latter requirement in particular required that the scope of the HTML5 specification include what had previously been specified in three separate documents: HTML4, XHTML1, and DOM2 HTML. It also meant including significantly more detail than had previously been considered the norm.

In 2006, the W3C indicated an interest to participate in the development of HTML5 after all, and in 2007 formed a working group chartered to work with the WHATWG on the development of the HTML5 specification. Apple, Mozilla, and Opera allowed the W3C to publish the specification under the W3C copyright, while keeping a version with the less restrictive license on the WHATWG site.

For a number of years, both groups then worked together. In 2011, however, the groups came to the conclusion that they had different goals: the W3C wanted to publish a "finished" version of "HTML5", while the WHATWG wanted to continue working on a Living Standard for HTML, continuously maintaining the specification rather than freezing it in a state with known problems, and adding new features as needed to evolve the platform.

Since then, the WHATWG has been working on this specification (amongst others), and the W3C has been copying fixes made by the WHATWG into their fork of the document, as well as making other changes, some intentional and some not, with no documentation listing or explaining the differences.

1.7 Design notes

This section is non-normative.

It must be admitted that many aspects of HTML appear at first glance to be nonsensical and inconsistent.

HTML, its supporting DOM APIs, as well as many of its supporting technologies, have been developed over a period of several decades by a wide array of people with different priorities who, in many cases, did not know of each other's existence.

Features have thus arisen from many sources, and have not always been designed in especially consistent ways. Furthermore, because of the unique characteristics of the Web, implementation bugs have often become de-facto, and now de-jure, standards, as content is often unintentionally written in ways that rely on them before they can be fixed.

Despite all this, efforts have been made to adhere to certain design goals. These are described in the next few subsections.

1.7.1 Serialisability of script execution

This section is non-normative.

To avoid exposing Web authors to the complexities of multithreading, the HTML and DOM APIs are designed such that no script can ever detect the simultaneous execution of other scripts. Even with [workers](#)^{p929}, the intent is that the behaviour of implementations can be thought of as completely serialising the execution of all scripts in all [browsing contexts](#)^{p762}.

Note The `navigator.yieldForStorageUpdates()`^{p868} method, in this model, is equivalent to allowing other scripts to run while the calling script is blocked.

1.7.2 Compliance with other specifications

This section is non-normative.

This specification interacts with and relies on a wide variety of other specifications. In certain circumstances, unfortunately, conflicting needs have led to this specification violating the requirements of these other specifications. Whenever this has occurred, the transgressions have each been noted as a "willful violation", and the reason for the violation has been noted.

1.7.3 Extensibility

This section is non-normative.

HTML has a wide array of extensibility mechanisms that can be used for adding semantics in a safe manner:

- Authors can use the `class`^{p128} attribute to extend elements, effectively creating their own elements, while using the most applicable existing "real" HTML element, so that browsers and other tools that don't know of the extension can still support it somewhat well. This is the tack used by microformats, for example.
- Authors can include data for inline client-side scripts or server-side site-wide scripts to process using the `data-*=""`^{p128} attributes. These are guaranteed to never be touched by browsers, and allow scripts to include data on HTML elements that scripts can then look for and process.
- Authors can use the `<meta name="" content="">`^{p145} mechanism to include page-wide metadata by registering [extensions to the predefined set of metadata names](#)^{b148}.
- Authors can use the `rel=""`^{p246} mechanism to annotate links with specific meanings by registering [extensions to the predefined set of link types](#)^{p259}. This is also used by microformats.
- Authors can embed raw data using the `<script type="">`^{p591} mechanism with a custom type, for further handling by inline or server-side scripts.
- Authors can create [plugins](#)^{p43} and invoke them using the `embed`^{p307} element. This is how Flash works.
- Authors can extend APIs using the JavaScript prototyping mechanism. This is widely used by script libraries, for instance.
- Authors can use the microdata feature (the `itemscope=""`^{p689} and `itemprop=""`^{p692} attributes) to embed nested name-value pairs of data to be shared with other applications and sites.

1.8 HTML vs XHTML

This section is non-normative.

This specification defines an abstract language for describing documents and applications, and some APIs for interacting with in-memory representations of resources that use this language.

The in-memory representation is known as "DOM HTML", or "the DOM" for short.

There are various concrete syntaxes that can be used to transmit resources that use this abstract language, two of which are defined in this specification.

The first such concrete syntax is the HTML syntax. This is the format suggested for most authors. It is compatible with most legacy Web browsers. If a document is transmitted with the `text/html`^{p1116} MIME type^{p42}, then it will be processed as an HTML document by Web browsers. This specification defines the latest HTML syntax, known simply as "HTML".

The second concrete syntax is the XHTML syntax, which is an application of XML. When a document is transmitted with an [XML MIME type^{p42}](#), such as [application/xhtml+xml^{p118}](#), then it is treated as an XML document by Web browsers, to be parsed by an XML processor. Authors are reminded that the processing for XML and HTML differs; in particular, even minor syntax errors will prevent a document labeled as XML from being rendered fully, whereas they would be ignored in the HTML syntax. This specification defines the latest XHTML syntax, known simply as "XHTML".

The DOM, the HTML syntax, and the XHTML syntax cannot all represent the same content. For example, namespaces cannot be represented using the HTML syntax, but they are supported in the DOM and in the XHTML syntax. Similarly, documents that use the [noscript^{p602}](#) feature can be represented using the HTML syntax, but cannot be represented with the DOM or in the XHTML syntax. Comments that contain the string "-->" can only be represented in the DOM, not in the HTML and XHTML syntaxes.

1.9 Structure of this specification

Spec bugs: [26942](#)

This section is non-normative.

This specification is divided into the following major sections:

[Introduction^{p23}](#)

Non-normative materials providing a context for the HTML standard.

[Common infrastructure^{p41}](#)

The conformance classes, algorithms, definitions, and the common underpinnings of the rest of the specification.

[Semantics, structure, and APIs of HTML documents^{p102}](#)

Documents are built from elements. These elements form a tree using the DOM. This section defines the features of this DOM, as well as introducing the features common to all elements, and the concepts used in defining elements.

[The elements of HTML^{p137}](#)

Each element has a predefined meaning, which is explained in this section. Rules for authors on how to use the element, along with user agent requirements for how to handle each element, are also given. This includes large signature features of HTML such as video playback and subtitles, form controls and form submission, and a 2D graphics API known as the HTML canvas.

[Microdata^{p683}](#)

This specification introduces a mechanism for adding machine-readable annotations to documents, so that tools can extract trees of name-value pairs from the document. This section describes this mechanism and some algorithms that can be used to convert HTML documents into other formats. This section also defines some sample Microdata vocabularies for contact information, calendar events, and licensing works.

[User interaction^{p723}](#)

HTML documents can provide a number of mechanisms for users to interact with and modify content, which are described in this section, such as how focus works, and drag-and-drop.

[Loading Web pages^{p762}](#)

HTML documents do not exist in a vacuum — this section defines many of the features that affect environments that deal with multiple pages, such as Web browsers and offline caching of Web applications.

[Web application APIs^{p828}](#)

This section introduces basic features for scripting of applications in HTML.

[Web workers^{p911}](#)

This section defines an API for background threads in JavaScript.

[The communication APIs^{p880}](#)

This section describes some mechanisms that applications written in HTML can use to communicate with other applications from different domains running on the same client. It also introduces a server-push event stream mechanism known as Server Sent Events or [EventSource^{p882}](#), and a two-way full-duplex socket protocol for scripts known as Web Sockets.

[Web storage^{p934}](#)

This section defines a client-side storage mechanism based on name-value pairs.

⋮

[The HTML syntax](#)^{p941}

[The XHTML syntax](#)^{p1054}

All of these features would be for naught if they couldn't be represented in a serialised form and sent to other people, and so these sections define the syntaxes of HTML and XHTML, along with rules for how to parse content using those syntaxes.

[Rendering](#)^{p1058}

This section defines the default rendering rules for Web browsers.

There are also some appendices, listing [obsolete features](#)^{p1095} and [IANA considerations](#)^{p1116}, and several indices.

1.9.1 How to read this specification

This specification should be read like all other specifications. First, it should be read cover-to-cover, multiple times. Then, it should be read backwards at least once. Then it should be read by picking random sections from the contents list and following all the cross-references.

As described in the conformance requirements section below, this specification describes conformance criteria for a variety of conformance classes. In particular, there are conformance requirements that apply to *producers*, for example authors and the documents they create, and there are conformance requirements that apply to *consumers*, for example Web browsers. They can be distinguished by what they are requiring: a requirement on a producer states what is allowed, while a requirement on a consumer states how software is to act.

Example

For example, "the `foo` attribute's value must be a [valid integer](#)^{p60}" is a requirement on producers, as it lays out the allowed values; in contrast, the requirement "the `foo` attribute's value must be parsed using the [rules for parsing integers](#)^{p60}" is a requirement on consumers, as it describes how to process the content.

Requirements on producers have no bearing whatsoever on consumers.

Example

Continuing the above example, a requirement stating that a particular attribute's value is constrained to being a [valid integer](#)^{p60} emphatically does *not* imply anything about the requirements on consumers. It might be that the consumers are in fact required to treat the attribute as an opaque string, completely unaffected by whether the value conforms to the requirements or not. It might be (as in the previous example) that the consumers are required to parse the value using specific rules that define how invalid (non-numeric in this case) values are to be processed.

1.9.2 Typographic conventions

This is a definition, requirement, or explanation.

Note *This is a note.*

Example This is an example.

This is an open issue.

⚠ Warning! *This is a warning.*

IDL

```
interface Example {  
    // this is an IDL definition  
};
```

Note

variable = object . method^{p29}([optionalArgument])

This is a note to authors describing the usage of an interface.

The defining instance of a term is marked up like **this**. Uses of that term are marked up like [this^{p29}](#) or like [this^{p29}](#).

The defining instance of an element, attribute, or API is marked up like **this**. References to that element, attribute, or API are marked up like [this^{p29}](#).

Other code fragments are marked up like `this`.

Variables are marked up like *this*.

In an algorithm, steps in [synchronous sections^{p837}](#) are marked with Σ .

In some cases, requirements are given in the form of lists with conditions and corresponding requirements. In such cases, the requirements that apply to a condition are always the first set of requirements that follow the condition, even in the case of there being multiple sets of conditions for those requirements. Such cases are presented as follows:

↪ **This is a condition**

↪ **This is another condition**

This is the requirement that applies to the conditions above.

↪ **This is a third condition**

This is the requirement that applies to the third condition.

1.10 Privacy concerns

This section is non-normative.

Some features of HTML trade user convenience for a measure of user privacy.

In general, due to the Internet's architecture, a user can be distinguished from another by the user's IP address. IP addresses do not perfectly match to a user; as a user moves from device to device, or from network to network, their IP address will change; similarly, NAT routing, proxy servers, and shared computers enable packets that appear to all come from a single IP address to actually map to multiple users. Technologies such as onion routing can be used to further anonymise requests so that requests from a single user at one node on the Internet appear to come from many disparate parts of the network.

However, the IP address used for a user's requests is not the only mechanism by which a user's requests could be related to each other. Cookies, for example, are designed specifically to enable this, and are the basis of most of the Web's session features that enable you to log into a site with which you have an account.

There are other mechanisms that are more subtle. Certain characteristics of a user's system can be used to distinguish groups of users from each other; by collecting enough such information, an individual user's browser's "digital fingerprint" can be computed, which can be as good, if not better, as an IP address in ascertaining which requests are from the same user.

Grouping requests in this manner, especially across multiple sites, can be used for both benign (and even arguably positive) purposes, as well as for malevolent purposes. An example of a reasonably benign purpose would be determining whether a particular person seems to prefer sites with dog illustrations as opposed to sites with cat illustrations (based on how often they visit the sites in question) and then automatically using the preferred illustrations on subsequent visits to participating sites. Malevolent purposes, however, could include governments combining information such as the person's home address (determined from the addresses they use when getting driving directions on one site) with their apparent political affiliations (determined by examining the forum sites that they participate in) to determine whether the person should be prevented from voting in an election.

Since the malevolent purposes can be remarkably evil, user agent implementors are encouraged to consider how to provide their users with tools to minimise leaking information that could be used to fingerprint a user.

Unfortunately, as the first paragraph in this section implies, sometimes there is great benefit to be derived from exposing the very information that can also be used for fingerprinting purposes, so it's not as easy as simply blocking all possible leaks. For instance, the ability to log into a site to post under a specific identity requires that the user's requests be identifiable as all being from the same user, more or less by definition. More subtly, though, information such as how wide text is, which is necessary for many effects that involve drawing text onto a canvas (e.g. any effect

that involves drawing a border around the text) also leaks information that can be used to group a user's requests. (In this case, by potentially exposing, via a brute force search, which fonts a user has installed, information which can vary considerably from user to user.)

Features in this specification which can be **used to fingerprint the user** are marked as this paragraph is.

Other features in the platform can be used for the same purpose, though, including, though not limited to:

- The exact list of which features a user agents supports.
- The maximum allowed stack depth for recursion in script.
- Features that describe the user's environment, like Media Queries and the [Screen](#)^{p53} object. [\[MQ\]](#)^{p1151} [\[CSSOMVIEW\]](#)^{p1149}
- The user's time zone.

1.10.1 Cross-site communication

The [postMessage \(\)](#)^{p900} API provides a mechanism by which two sites can communicate directly. At first glance, this might appear to open a new way by which the problems described above can occur. However, in practice, multiple mechanisms exist by which two sites can communicate that predate this API: a site embedding another can send data via an [iframe](#)^{p299} element's dimensions; a site can use a cross-site image request with a unique identifier known to the server to initiate a server-side data exchange; or indeed the fingerprinting techniques described above can be used by two sites to uniquely identify a visitor such that information can then be exchanged on the server side.

Fundamentally, users that do not trust a site to treat their information with respect have to avoid visiting that site at all.

1.11 A quick introduction to HTML

This section is non-normative.

A basic HTML document looks like this:

```
<!DOCTYPE html>
<html>
  <head>
    <title>Sample page</title>
  </head>
  <body>
    <h1>Sample page</h1>
    <p>This is a <a href="demo.html">simple</a> sample.</p>
    <!-- this is a comment -->
  </body>
</html>
```

HTML documents consist of a tree of elements and text. Each element is denoted in the source by a [start tag](#)^{p944}, such as "<body>", and an [end tag](#)^{p944}, such as "</body>". (Certain start tags and end tags can in certain cases be [omitted](#)^{p946} and are implied by other tags.)

Tags have to be nested such that elements are all completely within each other, without overlapping:

```
<p>This is <em>very <strong>wrong</em>!</strong></p>
<p>This <em>is <strong>correct</strong>.</em></p>
```

This specification defines a set of elements that can be used in HTML, along with rules about the ways in which the elements can be nested.

Elements can have attributes, which control how the elements work. In the example below, there is a [hyperlink](#)^{p245}, formed using the [a](#)^{p208} element and its [href](#)^{p245} attribute:

```
<a href="demo.html">simple</a>
```

[Attributes](#)^{p944} are placed inside the start tag, and consist of a [name](#)^{p944} and a [value](#)^{p944}, separated by an "=" character. The attribute value can remain [unquoted](#)^{p945} if it doesn't contain [space characters](#)^{p58} or any of " ! ` = < or >. Otherwise, it has to be quoted using either single or double quotes. The value, along with the "=" character, can be omitted altogether if the value is the empty string.

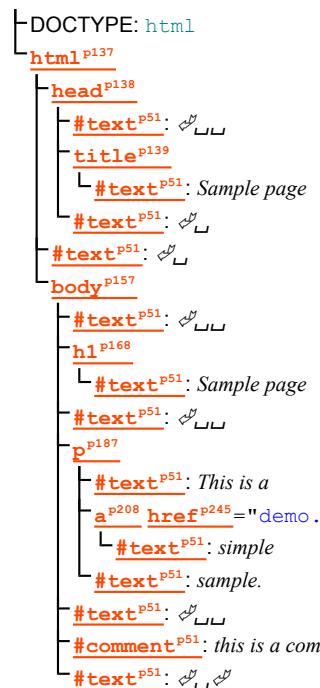

```
<!-- empty attributes -->
<input name=address disabled>
<input name=address disabled="">

<!-- attributes with a value -->
<input name=address maxlength=200>
<input name=address maxlength='200'>
<input name=address maxlength="200">
```

HTML user agents (e.g. Web browsers) then [parse](#) this markup, turning it into a DOM (Document Object Model) tree. A DOM tree is an in-memory representation of a document.

DOM trees contain several kinds of nodes, in particular a [DocumentType](#)^{p51} node, [Element](#)^{p51} nodes, [Text](#)^{p51} nodes, [Comment](#)^{p51} nodes, and in some cases [ProcessingInstruction](#)^{p51} nodes.

The [markup snippet at the top of this section](#)^{p30} would be turned into the following DOM tree:

The [root element](#)^{p42} of this tree is the [html](#)^{p137} element, which is the element always found at the root of HTML documents. It contains two elements, [head](#)^{p138} and [body](#)^{p157}, as well as a [Text](#)^{p51} node between them.

There are many more [Text](#)^{p51} nodes in the DOM tree than one would initially expect, because the source contains a number of spaces (represented here by " ") and line breaks ("") that all end up as [Text](#)^{p51} nodes in the DOM. However, for historical reasons not all of the spaces and line breaks in the original markup appear in the DOM. In particular, all the whitespace before [head](#)^{p138} start tag ends up being dropped silently, and all the whitespace after the [body](#)^{p157} end tag ends up placed at the end of the [body](#)^{p157}.

The [head](#)^{p138} element contains a [title](#)^{p139} element, which itself contains a [Text](#)^{p51} node with the text "Sample page". Similarly, the [body](#)^{p157} element contains an [h1](#)^{p168} element, a [p](#)^{p187} element, and a comment.

This DOM tree can be manipulated from scripts in the page. Scripts (typically in JavaScript) are small programs that can be embedded using the [script](#)^{p591} element or using [event handler content attributes](#)^{p839}. For example, here is a form with a script that sets the value of the form's [output](#)^{p516} element to say "Hello World":

```

<form name="main">
  Result: <output name="result"></output>
  <script>
    document.forms.main.elements.result.value = 'Hello World';
  </script>
</form>

```

Each element in the DOM tree is represented by an object, and these objects have APIs so that they can be manipulated. For instance, a link (e.g. the [a^{p208}](#) element in the tree above) can have its "[href^{p245}](#)" attribute changed in several ways:

```

var a = document.links[0]; // obtain the first link in the document
a.href = 'sample.html'; // change the destination URL of the link
a.protocol = 'https'; // change just the scheme part of the URL
a.setAttribute('href', 'http://example.com/'); // change the content attribute directly

```

Since DOM trees are used as the way to represent HTML documents when they are processed and presented by implementations (especially interactive implementations like Web browsers), this specification is mostly phrased in terms of DOM trees, instead of the markup described above.

HTML documents represent a media-independent description of interactive content. HTML documents might be rendered to a screen, or through a speech synthesiser, or on a braille display. To influence exactly how such rendering takes place, authors can use a styling language such as CSS.

In the following example, the page has been made yellow-on-blue using CSS.

```

<!DOCTYPE html>
<html>
  <head>
    <title>Sample styled page</title>
    <style>
      body { background: navy; color: yellow; }
    </style>
  </head>
  <body>
    <h1>Sample styled page</h1>
    <p>This page is just a demo.</p>
  </body>
</html>

```

For more details on how to use HTML, authors are encouraged to consult tutorials and guides. Some of the examples included in this specification might also be of use, but the novice author is cautioned that this specification, by necessity, defines the language with a level of detail that might be difficult to understand at first.

1.11.1 Writing secure applications with HTML

This section is non-normative.

When HTML is used to create interactive sites, care needs to be taken to avoid introducing vulnerabilities through which attackers can compromise the integrity of the site itself or of the site's users.

A comprehensive study of this matter is beyond the scope of this document, and authors are strongly encouraged to study the matter in more detail. However, this section attempts to provide a quick introduction to some common pitfalls in HTML application development.

The security model of the Web is based on the concept of "origins", and correspondingly many of the potential attacks on the Web involve cross-origin actions. [\[ORIGIN\]^{p1151}](#)

Not validating user input

Cross-site scripting (XSS)

SQL injection

When accepting untrusted input, e.g. user-generated content such as text comments, values in URL parameters, messages from third-party sites, etc, it is imperative that the data be validated before use, and properly escaped when displayed. Failing to do this can allow a hostile user to perform a variety of attacks, ranging from the potentially benign, such as providing bogus user information like a negative age, to the serious, such as running scripts every time a user looks at a page that includes the information, potentially propagating the attack in the process, to the catastrophic, such as deleting all data in the server.

When writing filters to validate user input, it is imperative that filters always be whitelist-based, allowing known-safe constructs and disallowing all other input. Blacklist-based filters that disallow known-bad inputs and allow everything else are not secure, as not everything that is bad is yet known (for example, because it might be invented in the future).

Example For example, suppose a page looked at its URL's query string to determine what to display, and the site then redirected the user to that page to display a message, as in:

```
<ul>
  <li><a href="message.cgi?say=Hello">Say Hello</a>
  <li><a href="message.cgi?say=Welcome">Say Welcome</a>
  <li><a href="message.cgi?say=Kittens">Say Kittens</a>
</ul>
```

If the message was just displayed to the user without escaping, a hostile attacker could then craft a URL that contained a script element:

```
http://example.com/message.cgi?say=%3Cscript%3Ealert%28%27Oh%20no%21%27%29%3C/script%3E
```

If the attacker then convinced a victim user to visit this page, a script of the attacker's choosing would run on the page. Such a script could do any number of hostile actions, limited only by what the site offers: if the site is an e-commerce shop, for instance, such a script could cause the user to unknowingly make arbitrarily many unwanted purchases.

This is called a cross-site scripting attack.

There are many constructs that can be used to try to trick a site into executing code. Here are some that authors are encouraged to consider when writing whitelist filters:

- When allowing harmless-seeming elements like [img](#), it is important to whitelist any provided attributes as well. If one allowed all attributes then an attacker could, for instance, use the [onload](#) attribute to run arbitrary script.
- When allowing URLs to be provided (e.g. for links), the scheme of each URL also needs to be explicitly whitelisted, as there are many schemes that can be abused. The most prominent example is "[javascript:](#)", but user agents can implement (and indeed, have historically implemented) others.
- Allowing a [base](#) element to be inserted means any [script](#) elements in the page with relative links can be hijacked, and similarly that any form submissions can get redirected to a hostile site.

Cross-site request forgery (CSRF)

If a site allows a user to make form submissions with user-specific side-effects, for example posting messages on a forum under the user's name, making purchases, or applying for a passport, it is important to verify that the request was made by the user intentionally, rather than by another site tricking the user into making the request unknowingly.

This problem exists because HTML forms can be submitted to other origins.

Sites can prevent such attacks by populating forms with user-specific hidden tokens, or by checking [Origin](#) headers on all requests.

Clickjacking

A page that provides users with an interface to perform actions that the user might not wish to perform needs to be designed so as to avoid the possibility that users can be tricked into activating the interface.

One way that a user could be so tricked is if a hostile site places the victim site in a small [iframe](#) and then convinces the user to click, for instance by having the user play a reaction game. Once the user is playing the game, the hostile site can quickly position the iframe under the mouse cursor just as the user is about to click, thus tricking the user into clicking the victim site's interface.

To avoid this, sites that do not expect to be used in frames are encouraged to only enable their interface if they detect that they are not in a frame (e.g. by comparing the `window`^{b769} object to the value of the `top`^{p764} attribute).

Spec bugs: [27316](#)

1.11.2 Common pitfalls to avoid when using the scripting APIs

This section is non-normative.

Scripts in HTML have "run-to-completion" semantics, meaning that the browser will generally run the script uninterrupted before doing anything else, such as firing further events or continuing to parse the document.

On the other hand, parsing of HTML files happens incrementally, meaning that the parser can pause at any point to let scripts run. This is generally a good thing, but it does mean that authors need to be careful to avoid hooking event handlers after the events could have possibly fired.

There are two techniques for doing this reliably: use [event handler content attributes](#)^{p839}, or create the element and add the event handlers in the same script. The latter is safe because, as mentioned earlier, scripts are run to completion before further events can fire.

Example

One way this could manifest itself is with `img`^{p272} elements and the `load`^{p1144} event. The event could fire as soon as the element has been parsed, especially if the image has already been cached (which is common).

Here, the author uses the `onload`^{p844} handler on an `img`^{p272} element to catch the `load`^{p1144} event:

```

```

If the element is being added by script, then so long as the event handlers are added in the same script, the event will still not be missed:

```
<script>
  var img = new Image();
  img.src = 'games.png';
  img.alt = 'Games';
  img.onload = gamesLogoHasLoaded;
  // img.addEventListener('load', gamesLogoHasLoaded, false); // would work also
</script>
```

However, if the author first created the `img`^{p272} element and then in a separate script added the event listeners, there's a chance that the `load`^{p1144} event would be fired in between, leading it to be missed:

```
<!-- Do not use this style, it has a race condition! -->

<!-- the 'load' event might fire here while the parser is taking a
     break, in which case you will not see it! -->
<script>
  var img = document.getElementById('games');
  img.onload = gamesLogoHasLoaded; // might never fire!
</script>
```

1.11.3 How to catch mistakes when writing HTML: validators and conformance checkers

This section is non-normative.

Authors are encouraged to make use of conformance checkers (also known as *validators*) to catch common mistakes. The WHATWG maintains a list of such tools at: <https://validator.whatwg.org/>

1.12 Conformance requirements for authors

This section is non-normative.

Unlike previous versions of the HTML specification, this specification defines in some detail the required processing for invalid documents as well as valid documents.

However, even though the processing of invalid content is in most cases well-defined, conformance requirements for documents are still important: in practice, interoperability (the situation in which all implementations process particular content in a reliable and identical or equivalent way) is not the only goal of document conformance requirements. This section details some of the more common reasons for still distinguishing between a conforming document and one with errors.

1.12.1 Presentational markup

This section is non-normative.

The majority of presentational features from previous versions of HTML are no longer allowed. Presentational markup in general has been found to have a number of problems:

The use of presentational elements leads to poorer accessibility

While it is possible to use presentational markup in a way that provides users of assistive technologies (ATs) with an acceptable experience (e.g. using ARIA), doing so is significantly more difficult than doing so when using semantically-appropriate markup. Furthermore, even using such techniques doesn't help make pages accessible for non-AT non-graphical users, such as users of text-mode browsers.

Using media-independent markup, on the other hand, provides an easy way for documents to be authored in such a way that they work for more users (e.g. text browsers).

Higher cost of maintenance

It is significantly easier to maintain a site written in such a way that the markup is style-independent. For example, changing the colour of a site that uses `` throughout requires changes across the entire site, whereas a similar change to a site based on CSS can be done by changing a single file.

Larger document sizes

Presentational markup tends to be much more redundant, and thus results in larger document sizes.

For those reasons, presentational markup has been removed from HTML in this version. This change should not come as a surprise; HTML4 deprecated presentational markup many years ago and provided a mode (HTML4 Transitional) to help authors move away from presentational markup; later, XHTML 1.1 went further and obsoleted those features altogether.

The only remaining presentational markup features in HTML are the `stylep128` attribute and the `stylep154` element. Use of the `stylep128` attribute is somewhat discouraged in production environments, but it can be useful for rapid prototyping (where its rules can be directly moved into a separate style sheet later) and for providing specific styles in unusual cases where a separate style sheet would be inconvenient. Similarly, the `stylep154` element can be useful in syndication or for page-specific styles, but in general an external style sheet is likely to be more convenient when the styles apply to multiple pages.

It is also worth noting that some elements that were previously presentational have been redefined in this specification to be media-independent: `bp236`, `ip235`, `hrp190`, `sp214`, `smallp212`, and `up237`.

1.12.2 Syntax errors

This section is non-normative.

The syntax of HTML is constrained to avoid a wide variety of problems.

Unintuitive error-handling behaviour

Certain invalid syntax constructs, when parsed, result in DOM trees that are highly unintuitive.

Example

For example, the following markup fragment results in a DOM with an `hr`^{p190} element that is an *earlier* sibling of the corresponding `table`^{p398} element:

```
<table><hr>...
```

Errors with optional error recovery

To allow user agents to be used in controlled environments without having to implement the more bizarre and convoluted error handling rules, user agents are permitted to fail whenever encountering a [parse error](#)^{p953}.

Errors where the error-handling behaviour is not compatible with streaming user agents

Some error-handling behaviour, such as the behaviour for the `<table><hr>...` example mentioned above, are incompatible with streaming user agents (user agents that process HTML files in one pass, without storing state). To avoid interoperability problems with such user agents, any syntax resulting in such behaviour is considered invalid.

Errors that can result in infoset coercion

When a user agent based on XML is connected to an HTML parser, it is possible that certain invariants that XML enforces, such as comments never containing two consecutive hyphens, will be violated by an HTML file. Handling this can require that the parser coerce the HTML DOM into an XML-compatible infoset. Most syntax constructs that require such handling are considered invalid.

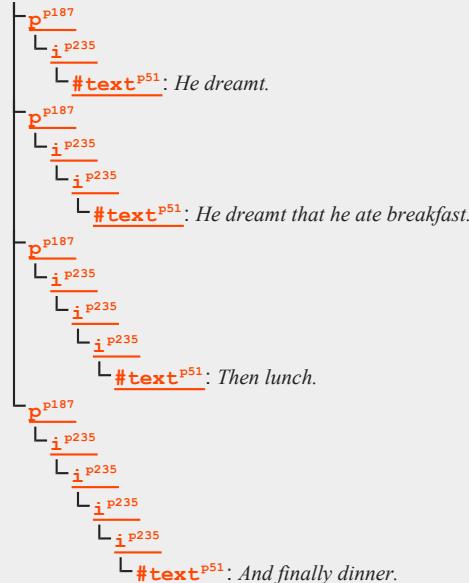

Errors that result in disproportionately poor performance

Certain syntax constructs can result in disproportionately poor performance. To discourage the use of such constructs, they are typically made non-conforming.

Example For example, the following markup results in poor performance, since all the unclosed `i`^{p235} elements have to be reconstructed in each paragraph, resulting in progressively more elements in each paragraph:

```
<p><i>He dreamt.  
<p><i>He dreamt that he ate breakfast.  
<p><i>Then lunch.  
<p><i>And finally dinner.
```

The resulting DOM for this fragment would be:

Errors involving fragile syntax constructs

There are syntax constructs that, for historical reasons, are relatively fragile. To help reduce the number of users who accidentally run into such problems, they are made non-conforming.

Example For example, the parsing of certain named character references in attributes happens even with the closing semicolon being omitted. It is safe to include an ampersand followed by letters that do not form a named character reference, but if the letters are changed to a string that *does* form a named character reference, they will be interpreted as that character instead.

In this fragment, the attribute's value is "?bill&ted":

```
<a href="?bill&ted">Bill and Ted</a>
```

In the following fragment, however, the attribute's value is actually "?art©", *not* the intended "?art©", because even without the final semicolon, "©" is handled the same as "©" and thus gets interpreted as "©":

```
<a href="?art&copy">Art and Copy</a>
```

To avoid this problem, all named character references are required to end with a semicolon, and uses of named character references without a semicolon are flagged as errors.

Thus, the correct way to express the above cases is as follows:

```
<a href="?bill&ted">Bill and Ted</a> <!-- &ted is ok, since it's not a named character reference -->
```

```
<a href="?art&copy">Art and Copy</a> <!-- the & has to be escaped, since &copy is a named character reference -->
```

Errors involving known interoperability problems in legacy user agents

Certain syntax constructs are known to cause especially subtle or serious problems in legacy user agents, and are therefore marked as non-conforming to help authors avoid them.

Example For example, this is why the U+0060 GRAVE ACCENT character (`) is not allowed in unquoted attributes. In certain legacy user agents, it is sometimes treated as a quote character.

Example Another example of this is the DOCTYPE, which is required to trigger [no-quirks mode^{p51}](#), because the behaviour of legacy user agents in [quirks mode^{p51}](#) is often largely undocumented.

Errors that risk exposing authors to security attacks

Certain restrictions exist purely to avoid known security problems.

Example For example, the restriction on using UTF-7 exists purely to avoid authors falling prey to a known cross-site-scripting attack using UTF-7. [\[UTF7\]^{p154}](#)

Cases where the author's intent is unclear

Markup where the author's intent is very unclear is often made non-conforming. Correcting these errors early makes later maintenance easier.

Example For example, it is unclear whether the author intended the following to be an [h1^{p168}](#) heading or an [h2^{p168}](#) heading:

```
<h1>Contact details</h2>
```

Cases that are likely to be typos

When a user makes a simple typo, it is helpful if the error can be caught early, as this can save the author a lot of debugging time. This specification therefore usually considers it an error to use element names, attribute names, and so forth, that do not match the names defined in this specification.

Example For example, if the author typed `<caption>` instead of `<caption>`, this would be flagged as an error and the author could correct the typo immediately.

Errors that could interfere with new syntax in the future

In order to allow the language syntax to be extended in the future, certain otherwise harmless features are disallowed.

Example For example, "attributes" in end tags are ignored currently, but they are invalid, in case a future change to the language makes use of that syntax feature without conflicting with already-deployed (and valid!) content.

Some authors find it helpful to be in the practice of always quoting all attributes and always including all optional tags, preferring the consistency derived from such custom over the minor benefits of terseness afforded by making use of the flexibility of the HTML syntax. To aid such authors, conformance checkers can provide modes of operation wherein such conventions are enforced.

1.12.3 Restrictions on content models and on attribute values

This section is non-normative.

Beyond the syntax of the language, this specification also places restrictions on how elements and attributes can be specified. These restrictions are present for similar reasons:

Errors involving content with dubious semantics

To avoid misuse of elements with defined meanings, content models are defined that restrict how elements can be nested when such nestings would be of dubious value.

Example For example, this specification disallows nesting a `sectionp161` element inside a `kbdp234` element, since it is highly unlikely for an author to indicate that an entire section should be keyed in.

Errors that involve a conflict in expressed semantics

Similarly, to draw the author's attention to mistakes in the use of elements, clear contradictions in the semantics expressed are also considered conformance errors.

Example In the fragments below, for example, the semantics are nonsensical: a separator cannot simultaneously be a cell, nor can a radio button be a progress bar.

```
<hr role="cell">  
  
<input type=radio role=progressbar>
```

Example Another example is the restrictions on the content models of the `ulp197` element, which only allows `lip198` element children. Lists by definition consist just of zero or more list items, so if a `ulp197` element contains something other than an `lip198` element, it's not clear what was meant.

Cases where the default styles are likely to lead to confusion

Certain elements have default styles or behaviours that make certain combinations likely to lead to confusion. Where these have equivalent alternatives without this problem, the confusing combinations are disallowed.

Example For example, `divp207` elements are rendered as block boxes, and `spanp242` elements as inline boxes. Putting a block box in an inline box is unnecessarily confusing; since either nesting just `divp207` elements, or nesting just `spanp242` elements, or nesting `spanp242` elements inside `divp207` elements all serve the same purpose as nesting a `divp207` element in a `spanp242` element, but only the latter involves a block box in an inline box, the latter combination is disallowed.

Example Another example would be the way `interactive contentp116` cannot be nested. For example, a `buttonp495` element cannot contain a `textareap508` element. This is because the default behaviour of such nesting interactive elements would be highly confusing to users. Instead of nesting these elements, they can be placed side by side.

Errors that indicate a likely misunderstanding of the specification

Sometimes, something is disallowed because allowing it would likely cause author confusion.

Example For example, setting the `disabledp530` attribute to the value "false" is disallowed, because despite the appearance of meaning that the element is enabled, it in fact means that the element is *disabled* (what matters for implementations is the presence of the attribute, not its value).

Errors involving limits that have been imposed merely to simplify the language

Some conformance errors simplify the language that authors need to learn.

Example For example, the `areap390` element's `shapep391` attribute, despite accepting both `circp391` and `circlep391` values in practice as synonyms, disallows the use of the `circp391` value, so as to simplify tutorials and other learning aids. There would be no benefit to allowing both, but it would cause extra confusion when teaching the language.

Errors that involve peculiarities of the parser

Certain elements are parsed in somewhat eccentric ways (typically for historical reasons), and their content model restrictions are intended to avoid exposing the author to these issues.

Example For example, a `formp447` element isn't allowed inside `phrasing contentp116`, because when parsed as HTML, a `formp447` element's start tag will imply a `pp187` element's end tag. Thus, the following markup results in two `paragraphsp118`, not one:

```
<p>Welcome. <form><label>Name:</label> <input></form>
```

It is parsed exactly like the following:

```
<p>Welcome. </p><form><label>Name:</label> <input></form>
```

Errors that would likely result in scripts failing in hard-to-debug ways

Some errors are intended to help prevent script problems that would be hard to debug.

Example This is why, for instance, it is non-conforming to have two `id`^{p122} attributes with the same value. Duplicate IDs lead to the wrong element being selected, with sometimes disastrous effects whose cause is hard to determine.

Errors that waste authoring time

Some constructs are disallowed because historically they have been the cause of a lot of wasted authoring time, and by encouraging authors to avoid making them, authors can save time in future efforts.

Example For example, a `script`^{p591} element's `src`^{p592} attribute causes the element's contents to be ignored. However, this isn't obvious, especially if the element's contents appear to be executable script — which can lead to authors spending a lot of time trying to debug the inline script without realizing that it is not executing. To reduce this problem, this specification makes it non-conforming to have executable script in a `script`^{p591} element when the `src`^{p592} attribute is present. This means that authors who are validating their documents are less likely to waste time with this kind of mistake.

Errors that involve areas that affect authors migrating to and from XHTML

Some authors like to write files that can be interpreted as both XML and HTML with similar results. Though this practice is discouraged in general due to the myriad of subtle complications involved (especially when involving scripting, styling, or any kind of automated serialisation), this specification has a few restrictions intended to at least somewhat mitigate the difficulties. This makes it easier for authors to use this as a transitional step when migrating between HTML and XHTML.

Example For example, there are somewhat complicated rules surrounding the `lang`^{p123} and `xml:lang`^{p123} attributes intended to keep the two synchronised.

Example Another example would be the restrictions on the values of `xmlns` attributes in the HTML serialisation, which are intended to ensure that elements in conforming documents end up in the same namespaces whether processed as HTML or XML.

Errors that involve areas reserved for future expansion

As with the restrictions on the syntax intended to allow for new syntax in future revisions of the language, some restrictions on the content models of elements and values of attributes are intended to allow for future expansion of the HTML vocabulary.

Example For example, limiting the values of the `target`^{p245} attribute that start with an U+005F LOW LINE character (_) to only specific predefined values allows new predefined values to be introduced at a future time without conflicting with author-defined values.

Errors that indicate a mis-use of other specifications

Certain restrictions are intended to support the restrictions made by other specifications.

Example For example, requiring that attributes that take media query lists use only *valid* media query lists reinforces the importance of following the conformance rules of that specification.

1.13 Suggested reading

This section is non-normative.

The following documents might be of interest to readers of this specification.

Character Model for the World Wide Web 1.0: Fundamentals [CHARMOD]^{p1148}

This Architectural Specification provides authors of specifications, software developers, and content developers with a common reference for interoperable text manipulation on the World Wide Web, building on the Universal Character Set, defined jointly by the Unicode Standard and ISO/IEC 10646. Topics addressed include use of the terms 'character', 'encoding' and 'string', a reference processing model, choice and identification of character encodings, character escaping, and string indexing.

Unicode Security Considerations [\[UTR36\]](#)^{p1154}

Because Unicode contains such a large number of characters and incorporates the varied writing systems of the world, incorrect usage can expose programs or systems to possible security attacks. This is especially important as more and more products are internationalized. This document describes some of the security considerations that programmers, system analysts, standards developers, and users should take into account, and provides specific recommendations to reduce the risk of problems.

Web Content Accessibility Guidelines (WCAG) 2.0 [\[WCAG\]](#)^{p1154}

Web Content Accessibility Guidelines (WCAG) 2.0 covers a wide range of recommendations for making Web content more accessible. Following these guidelines will make content accessible to a wider range of people with disabilities, including blindness and low vision, deafness and hearing loss, learning disabilities, cognitive limitations, limited movement, speech disabilities, photosensitivity and combinations of these. Following these guidelines will also often make your Web content more usable to users in general.

Authoring Tool Accessibility Guidelines (ATAG) 2.0 [\[ATAG\]](#)^{p1148}

This specification provides guidelines for designing Web content authoring tools that are more accessible for people with disabilities. An authoring tool that conforms to these guidelines will promote accessibility by providing an accessible user interface to authors with disabilities as well as by enabling, supporting, and promoting the production of accessible Web content by all authors.

User Agent Accessibility Guidelines (UAAG) 2.0 [\[UAAG\]](#)^{p1153}

This document provides guidelines for designing user agents that lower barriers to Web accessibility for people with disabilities. User agents include browsers and other types of software that retrieve and render Web content. A user agent that conforms to these guidelines will promote accessibility through its own user interface and through other internal facilities, including its ability to communicate with other technologies (especially assistive technologies). Furthermore, all users, not just users with disabilities, should find conforming user agents to be more usable.

2 Common infrastructure

2.1 Terminology

This specification refers to both HTML and XML attributes and IDL attributes, often in the same context. When it is not clear which is being referred to, they are referred to as **content attributes** for HTML and XML attributes, and **IDL attributes** for those defined on IDL interfaces. Similarly, the term "properties" is used for both JavaScript object properties and CSS properties. When these are ambiguous they are qualified as **object properties** and **CSS properties** respectively.

Generally, when the specification states that a feature applies to [the HTML syntax^{p941}](#) or [the XHTML syntax^{p1054}](#), it also includes the other. When a feature specifically only applies to one of the two languages, it is called out by explicitly stating that it does not apply to the other format, as in "for HTML, ... (this does not apply to XHTML)".

This specification uses the term **document** to refer to any use of HTML, ranging from short static documents to long essays or reports with rich multimedia, as well as to fully-fledged interactive applications. The term is used to refer both to [Document^{p102}](#) objects and their descendant DOM trees, and to serialised byte streams using the [HTML syntax^{p941}](#) or [XHTML syntax^{p1054}](#), depending on context.

In the context of the DOM structures, the terms [HTML document^{p51}](#) and [XML document^{p51}](#) are used as defined in the DOM specification, and refer specifically to two different modes that [Document^{p102}](#) objects can find themselves in. [\[DOM\]^{p1149}](#) (Such uses are always hyperlinked to their definition.)

In the context of byte streams, the term **HTML document** refers to resources labeled as [text/html^{p1116}](#), and the term **XML document** refers to resources labeled with an [XML MIME type^{p42}](#).

The term **XHTML document** is used to refer to both [Document^{p102}](#)s in the [XML document^{p51}](#) mode that contains element nodes in the [HTML namespace^{p101}](#), and byte streams labeled with an [XML MIME type^{p42}](#) that contain elements from the [HTML namespace^{p101}](#), depending on context.

For simplicity, terms such as **shown**, **displayed**, and **visible** might sometimes be used when referring to the way a document is rendered to the user. These terms are not meant to imply a visual medium; they must be considered to apply to other media in equivalent ways.

When an algorithm B says to return to another algorithm A, it implies that A called B. Upon returning to A, the implementation must continue from where it left off in calling B. Some algorithms run **in parallel**; this means that the algorithm's subsequent steps are to be run, one after another, at the same time as other logic in the specification (e.g. at the same time as the [event loop^{p834}](#)). This specification does not define the precise mechanism by which this is achieved, be it time-sharing cooperative multitasking, fibers, threads, processes, using different hyperthreads, cores, CPUs, machines, etc. By contrast, an operation that is to run **immediately** must interrupt the currently running task, run itself, and then resume the previously running task.

The term "transparent black" refers to the colour with red, green, blue, and alpha channels all set to zero.

2.1.1 Resources

The specification uses the term **supported** when referring to whether a user agent has an implementation capable of decoding the semantics of an external resource. A format or type is said to be **supported** if the implementation can process an external resource of that format or type without critical aspects of the resource being ignored. Whether a specific resource is **supported** can depend on what features of the resource's format are in use.

Example For example, a PNG image would be considered to be in a supported format if its pixel data could be decoded and rendered, even if, unbeknownst to the implementation, the image also contained animation data.

Example An MPEG-4 video file would not be considered to be in a supported format if the compression format used was not supported, even if the implementation could determine the dimensions of the movie from the file's metadata.

What some specifications, in particular the HTTP specification, refer to as a **representation** is referred to in this specification as a **resource**. [\[HTTP\]^{p150}](#)

The term **MIME type** is used to refer to what is sometimes called an *Internet media type* in protocol literature. The term *media type* in this specification is used to refer to the type of media intended for presentation, as used by the CSS specifications. [RFC2046]^{p1152} [MQ]^{p1151}

A string is a **valid MIME type** if it matches the `media-type` rule defined in [section 3.1.1.1 "Media Type" of RFC 7231](#). In particular, a **valid MIME type**^{p42} may include MIME type parameters. [HTTP]^{p1150}

A string is a **valid MIME type with no parameters** if it matches the `media-type` rule defined in [section 3.1.1.1 "Media Type" of RFC 7231](#), but does not contain any U+003B SEMICOLON characters (;). In other words, if it consists only of a type and subtype, with no MIME Type parameters. [HTTP]^{p1150}

The term **HTML MIME type** is used to refer to the [MIME type](#)^{p42} [text/html](#)^{p1116}.

A resource's **critical subresources** are those that the resource needs to have available to be correctly processed. Which resources are considered critical or not is defined by the specification that defines the resource's format.

Spec bugs: 17011

2.1.2 XML

To ease migration from HTML to XHTML, UAs conforming to this specification will place elements in HTML in the <http://www.w3.org/1999/xhtml>^{p101} namespace, at least for the purposes of the DOM and CSS. The term "**HTML elements**", when used in this specification, refers to any element in that namespace, and thus refers to both HTML and XHTML elements.

Except where otherwise stated, all elements defined or mentioned in this specification are in the [HTML namespace](#)^{p101} ("http://www.w3.org/1999/xhtml"), and all attributes defined or mentioned in this specification have no namespace.

The term **element type** is used to refer to the set of elements that have a given local name and namespace. For example, [button](#)^{p495} elements are elements with the element type [button](#)^{p495}, meaning they have the local name "button" and (implicitly as defined above) the [HTML namespace](#)^{p101}.

Attribute names are said to be **XML-compatible** if they match the [Name](#) production defined in XML and they contain no U+003A COLON characters (:). [XML]^{p1154}

The term **XML MIME type** is used to refer to the [MIME types](#)^{p42} [text/xml](#)^{p1147}, [application/xml](#)^{p1145}, and any [MIME type](#)^{p42} whose subtype ends with the four characters "+xml". [RFC7303]^{p1153}

2.1.3 DOM trees

The **root element of a Document object** is that [Document](#)^{p102}'s first element child, if any. If it does not have one then the [Document](#)^{p102} has no root element.

The term **root element**, when not referring to a [Document](#)^{p102} object's root element, means the furthest ancestor element node of whatever node is being discussed, or the node itself if it has no ancestors. When the node is a part of the document, then the node's [root element](#)^{p42} is indeed the document's root element; however, if the node is not currently part of the document tree, the root element will be an orphaned node.

When an element's [root element](#)^{p42} is the [root element of a Document object](#)^{p42}, it is said to be **in a Document**. An element is said to have been **inserted into a document** when its [root element](#)^{p42} changes and is now the document's [root element](#)^{p42}. Analogously, an element is said to have been **removed from a document** when its [root element](#)^{p42} changes from being the document's [root element](#)^{p42} to being another element.

A node's **home subtree** is the subtree rooted at that node's [root element](#)^{p42}. When a node is [in a Document](#)^{p42}, its [home subtree](#)^{p42} is that [Document](#)^{p102}'s tree.

The term **tree order** means a pre-order, depth-first traversal of DOM nodes involved (through the [parentNode](#)^{p51}/[childNodes](#)^{p51} relationship).

When it is stated that some element or attribute is **ignored**, or treated as some other value, or handled as if it was something else, this refers only to the processing of the node after it is in the DOM. A user agent must not mutate the DOM in such situations.

A content attribute is said to **change** value only if its new value is different than its previous value; setting an attribute to a value it already has does not change it.

The term **empty**, when used of an attribute value, [Text^{p51}](#) node, or string, means that the length of the text is zero (i.e. not even containing spaces or [control characters^{p58}](#)).

A **node A is inserted** into a node *B* when the [insertion steps](#) are invoked with *A* as the argument and *A*'s new parent is *B*. Similarly, a **node A is removed** from a node *B* when the [removing steps](#) are invoked with *A* as the *removedNode* argument and *B* as the *oldParent* argument.

2.1.4 Scripting

The construction "a `Foo` object", where `Foo` is actually an interface, is sometimes used instead of the more accurate "an object implementing the interface `Foo`".

An IDL attribute is said to be **getting** when its value is being retrieved (e.g. by author script), and is said to be **setting** when a new value is assigned to it.

If a DOM object is said to be **live**, then the attributes and methods on that object must operate on the actual underlying data, not a snapshot of the data.

In the contexts of events, the terms *fire* and *dispatch* are used as defined in the DOM specification: **firing** an event means to create and [dispatch^{p43}](#) it, and **dispatching** an event means to follow the steps that propagate the event through the tree. The term **trusted event** is used to refer to events whose [isTrusted^{p51}](#) attribute is initialised to true. [\[DOM\]^{p149}](#)

2.1.5 Plugins

The term **plugin** refers to a user-agent defined set of content handlers used by the user agent that can take part in the user agent's rendering of a [Document^{p102}](#) object, but that neither act as [child browsing contexts^{p763}](#) of the [Document^{p102}](#) nor introduce any [Node^{p51}](#) objects to the [Document^{p102}](#)'s DOM.

Typically such content handlers are provided by third parties, though a user agent can also designate built-in content handlers as plugins.

A user agent must not consider the types [text/plain](#) and [application/octet-stream](#) as having a registered [plugin^{p43}](#).

Example One example of a plugin would be a PDF viewer that is instantiated in a [browsing context^{p762}](#) when the user navigates to a PDF file. This would count as a plugin regardless of whether the party that implemented the PDF viewer component was the same as that which implemented the user agent itself. However, a PDF viewer application that launches separate from the user agent (as opposed to using the same interface) is not a plugin by this definition.

Note *This specification does not define a mechanism for interacting with plugins, as it is expected to be user-agent- and platform-specific. Some UAs might opt to support a plugin mechanism such as the Netscape Plugin API; others might use remote content converters or have built-in support for certain types. Indeed, this specification doesn't require user agents to support plugins at all. [\[NPAPI\]^{p1151}](#)*

A plugin can be **secured** if it honors the semantics of the [sandbox^{p303}](#) attribute.

Example For example, a secured plugin would prevent its contents from creating pop-up windows when the plugin is instantiated inside a sandboxed [iframe^{p299}](#).

⚠ Warning! *Browsers should take extreme care when interacting with external content intended for [plugins^{p43}](#). When third-party software is run with the same privileges as the user agent itself, vulnerabilities in the third-party software become as dangerous as those in the user agent.*

Since different users having different sets of [plugins^{p43}](#) provides a fingerprinting vector that increases the chances of users being uniquely identified, user agents are encouraged to support the exact same set of [plugins^{p43}](#) for each user.

2.1.6 Character encodings

A **character encoding**, or just *encoding* where that is not ambiguous, is a defined way to convert between byte streams and Unicode strings, as defined in the WHATWG Encoding standard. An [encoding^{p44}](#) has an **encoding name** and one or more **encoding labels**, referred to as the encoding's *name* and *labels* in the Encoding standard. [\[ENCODING\]^{p1150}](#)

An **ASCII-compatible character encoding** is a single-byte or variable-length [encoding^{p44}](#) in which the bytes 0x09, 0x0A, 0x0C, 0x0D, 0x20 - 0x22, 0x26, 0x27, 0x2C - 0x3F, 0x41 - 0x5A, and 0x61 - 0x7A, ignoring bytes that are the second and later bytes of multibyte sequences, all correspond to single-byte sequences that map to the same Unicode characters as those bytes in Windows-1252. [\[ENCODING\]^{p1150}](#)

Note This includes such encodings as Shift_JIS, HZ-GB-2312, and variants of ISO-2022, even though it is possible in these encodings for bytes like 0x70 to be part of longer sequences that are unrelated to their interpretation as ASCII. It excludes UTF-16 variants, as well as obsolete legacy encodings such as UTF-7, GSM03.38, and EBCDIC variants.

The term a **UTF-16 encoding** refers to any variant of UTF-16: UTF-16LE or UTF-16BE, regardless of the presence or absence of a ROM [\[ENCODING\]^{p1150}](#) Spec bugs: [24120](#)

The term **code unit** is used as defined in the Web IDL specification: a 16 bit unsigned integer, the smallest atomic component of a [DOMString^{p49}](#). (This is a narrower definition than the one used in Unicode, and is not the same as a *code point*). [\[WEBIDL\]^{p1154}](#)

The term **Unicode code point** means a *Unicode scalar value* where possible, and an isolated surrogate code point when not. When a conformance requirement is defined in terms of characters or Unicode code points, a pair of [code units^{p44}](#) consisting of a high surrogate followed by a low surrogate must be treated as the single code point represented by the surrogate pair, but isolated surrogates must each be treated as the single code point with the value of the surrogate. [\[UNICODE\]^{p1153}](#)

In this specification, the term **character**, when not qualified as *Unicode character*, is synonymous with the term [Unicode code point^{p44}](#).

The term **Unicode character** is used to mean a *Unicode scalar value* (i.e. any Unicode code point that is not a surrogate code point). [\[UNICODE\]^{p1153}](#)

The **code-unit length** of a string is the number of [code units^{p44}](#) in that string.

Note This complexity results from the historical decision to define the DOM API in terms of 16 bit (UTF-16) [code units^{p44}](#), rather than in terms of [Unicode characters^{p44}](#).

2.2 Conformance requirements

All diagrams, examples, and notes in this specification are non-normative, as are all sections explicitly marked non-normative. Everything else in this specification is normative.

The key words "MUST", "MUST NOT", "SHOULD", "SHOULD NOT", "MAY", and "OPTIONAL" in the normative parts of this document are to be interpreted as described in RFC2119. The key word "OPTIONALLY" in the normative parts of this document is to be interpreted with the same normative meaning as "MAY" and "OPTIONAL". For readability, these words do not appear in all uppercase letters in this specification. [\[RFC2119\]^{p1152}](#)

Requirements phrased in the imperative as part of algorithms (such as "strip any leading space characters" or "return false and abort these steps") are to be interpreted with the meaning of the key word ("must", "should", "may", etc) used in introducing the algorithm.

Example

For example, were the spec to say:

- To eat an orange, the user must:
 1. Peel the orange.
 2. Separate each slice of the orange.
 3. Eat the orange slices.

...it would be equivalent to the following:

- To eat an orange:
 1. The user must peel the orange.

2. The user must separate each slice of the orange.
3. The user must eat the orange slices.

Here the key word is "must".

The former (imperative) style is generally preferred in this specification for stylistic reasons.

Conformance requirements phrased as algorithms or specific steps may be implemented in any manner, so long as the end result is equivalent. (In particular, the algorithms defined in this specification are intended to be easy to follow, and not intended to be performant.)

2.2.1 Conformance classes

This specification describes the conformance criteria for user agents (relevant to implementors) and documents (relevant to authors and authoring tool implementors).

Conforming documents are those that comply with all the conformance criteria for documents. For readability, some of these conformance requirements are phrased as conformance requirements on authors; such requirements are implicitly requirements on documents: by definition, all documents are assumed to have had an author. (In some cases, that author may itself be a user agent — such user agents are subject to additional rules, as explained below.)

Example For example, if a requirement states that "authors must not use the `foobar` element", it would imply that documents are not allowed to contain elements named `foobar`.

Note *There is no implied relationship between document conformance requirements and implementation conformance requirements. User agents are not free to handle non-conformant documents as they please; the processing model described in this specification applies to implementations regardless of the conformity of the input documents.*

User agents fall into several (overlapping) categories with different conformance requirements.

Web browsers and other interactive user agents

Web browsers that support the [XHTML syntax^{p1054}](#) must process elements and attributes from the [HTML namespace^{p101}](#) found in XML documents as described in this specification, so that users can interact with them, unless the semantics of those elements have been overridden by other specifications.

Example A conforming XHTML processor would, upon finding an XHTML `script`^{p591} element in an XML document, execute the script contained in that element. However, if the element is found within a transformation expressed in XSLT (assuming the user agent also supports XSLT), then the processor would instead treat the `script`^{p591} element as an opaque element that forms part of the transform.

Web browsers that support the [HTML syntax^{p941}](#) must process documents labeled with an [HTML MIME type^{p42}](#) as described in this specification, so that users can interact with them.

User agents that support scripting must also be conforming implementations of the IDL fragments in this specification, as described in the Web IDL specification. [\[WEBIDL\]^{p1154}](#)

Note *Unless explicitly stated, specifications that override the semantics of HTML elements do not override the requirements on DOM objects representing those elements. For example, the `script`^{p591} element in the example above would still implement the [HTMLScriptElement^{p592}](#) interface.*

Non-interactive presentation user agents

User agents that process HTML and XHTML documents purely to render non-interactive versions of them must comply to the same conformance criteria as Web browsers, except that they are exempt from requirements regarding user interaction.

Note *Typical examples of non-interactive presentation user agents are printers (static UAs) and overhead displays (dynamic UAs). It is expected that most static non-interactive presentation user agents will also opt to lack scripting support^{p46}.*

Example A non-interactive but dynamic presentation UA would still execute scripts, allowing forms to be dynamically submitted, and so forth. However, since the concept of "focus" is irrelevant when the user cannot interact with the document, the UA would not need to support any of the focus-related DOM APIs.

Visual user agents that support the suggested default rendering

User agents, whether interactive or not, may be designated (possibly as a user option) as supporting the suggested default rendering defined by this specification.

This is not required. In particular, even user agents that do implement the suggested default rendering are encouraged to offer settings that override this default to improve the experience for the user, e.g. changing the colour contrast, using different focus styles, or otherwise making the experience more accessible and usable to the user.

User agents that are designated as supporting the suggested default rendering must, while so designated, implement the rules in [the rendering section](#)^{p1058} that that section defines as the behaviour that user agents are *expected* to implement.

User agents with no scripting support

Implementations that do not support scripting (or which have their scripting features disabled entirely) are exempt from supporting the events and DOM interfaces mentioned in this specification. For the parts of this specification that are defined in terms of an events model or in terms of the DOM, such user agents must still act as if events and the DOM were supported.

Note *Scripting can form an integral part of an application. Web browsers that do not support scripting, or that have scripting disabled, might be unable to fully convey the author's intent.*

Conformance checkers

Conformance checkers must verify that a document conforms to the applicable conformance criteria described in this specification.

Automated conformance checkers are exempt from detecting errors that require interpretation of the author's intent (for example, while a document is non-conforming if the content of a [blockquote](#)^{p193} element is not a quote, conformance checkers running without the input of human judgement do not have to check that [blockquote](#)^{p193} elements only contain quoted material).

Conformance checkers must check that the input document conforms when parsed without a [browsing context](#)^{p762} (meaning that no scripts are run, and that the parser's [scripting flag](#)^{p965} is disabled), and should also check that the input document conforms when parsed with a [browsing context](#)^{p762} in which scripts execute, and that the scripts never cause non-conforming states to occur other than transiently during script execution itself. (This is only a "SHOULD" and not a "MUST" requirement because it has been proven to be impossible. [\[COMPUTABLE\]](#)^{p1148})

The term "HTML validator" can be used to refer to a conformance checker that itself conforms to the applicable requirements of this specification.

Note *XML DTDs cannot express all the conformance requirements of this specification. Therefore, a validating XML processor and a DTD cannot constitute a conformance checker. Also, since neither of the two authoring formats defined in this specification are applications of SGML, a validating SGML system cannot constitute a conformance checker either.*

To put it another way, there are three types of conformance criteria:

1. *Criteria that can be expressed in a DTD.*
2. *Criteria that cannot be expressed by a DTD, but can still be checked by a machine.*
3. *Criteria that can only be checked by a human.*

A conformance checker must check for the first two. A simple DTD-based validator only checks for the first class of errors and is therefore not a conforming conformance checker according to this specification.

Data mining tools

Applications and tools that process HTML and XHTML documents for reasons other than to either render the documents or check them for conformance should act in accordance with the semantics of the documents that they process.

Example A tool that generates [document outlines](#)^{p178} but increases the nesting level for each paragraph and does not increase the nesting level for each section would not be conforming.

Authoring tools and markup generators

Authoring tools and markup generators must generate [conforming documents](#)^{p45}. Conformance criteria that apply to authors also apply to authoring tools, where appropriate.

Authoring tools are exempt from the strict requirements of using elements only for their specified purpose, but only to the extent that authoring tools are not yet able to determine author intent. However, authoring tools must not automatically misuse elements or encourage their users to do so.

Example For example, it is not conforming to use an [address^{p175}](#) element for arbitrary contact information; that element can only be used for marking up contact information for the author of the document or section. However, since an authoring tool is likely unable to determine the difference, an authoring tool is exempt from that requirement. This does not mean, though, that authoring tools can use [address^{p175}](#) elements for any block of italics text (for instance); it just means that the authoring tool doesn't have to verify that when the user uses a tool for inserting contact information for a section, that the user really is doing that and not inserting something else instead.

Note *In terms of conformance checking, an editor has to output documents that conform to the same extent that a conformance checker will verify.*

When an authoring tool is used to edit a non-conforming document, it may preserve the conformance errors in sections of the document that were not edited during the editing session (i.e. an editing tool is allowed to round-trip erroneous content). However, an authoring tool must not claim that the output is conformant if errors have been so preserved.

Authoring tools are expected to come in two broad varieties: tools that work from structure or semantic data, and tools that work on a What-You-See-Is-What-You-Get media-specific editing basis (WYSIWYG).

The former is the preferred mechanism for tools that author HTML, since the structure in the source information can be used to make informed choices regarding which HTML elements and attributes are most appropriate.

However, WYSIWYG tools are legitimate. WYSIWYG tools should use elements they know are appropriate, and should not use elements that they do not know to be appropriate. This might in certain extreme cases mean limiting the use of flow elements to just a few elements, like [div^{p207}](#), [b^{p236}](#), [i^{p235}](#), and [span^{p242}](#) and making liberal use of the [style^{p128}](#) attribute.

All authoring tools, whether WYSIWYG or not, should make a best effort attempt at enabling users to create well-structured, semantically rich, media-independent content.

User agents may impose implementation-specific limits on otherwise unconstrained inputs, e.g. to prevent denial of service attacks, to guard against running out of memory, or to work around platform-specific limitations.

For compatibility with existing content and prior specifications, this specification describes two authoring formats: one based on XML (referred to as [the XHTML syntax^{p1054}](#)), and one using a [custom format^{p941}](#) inspired by SGML (referred to as [the HTML syntax^{p941}](#)). Implementations must support at least one of these two formats, although supporting both is encouraged.

Some conformance requirements are phrased as requirements on elements, attributes, methods or objects. Such requirements fall into two categories: those describing content model restrictions, and those describing implementation behaviour. Those in the former category are requirements on documents and authoring tools. Those in the second category are requirements on user agents. Similarly, some conformance requirements are phrased as requirements on authors; such requirements are to be interpreted as conformance requirements on the documents that authors produce. (In other words, this specification does not distinguish between conformance criteria on authors and conformance criteria on documents.)

2.2.2 Dependencies

This specification relies on several other underlying specifications.

Unicode and Encoding

The Unicode character set is used to represent textual data, and the WHATWG Encoding standard defines requirements around [character encodings^{p44}](#). [\[UNICODE\]^{p1153}](#)

Note *This specification introduces terminology^{p44} based on the terms defined in those specifications, as described earlier.*

The following terms are used as defined in the WHATWG Encoding standard: [\[ENCODING\]^{p1150}](#)

- [Getting an encoding](#)
- The [encoder](#) and [decoder](#) algorithms for various encodings, including the [UTF-8 encoder](#) and [UTF-8 decoder](#)
- The generic [decode](#) algorithm which takes a byte stream and an encoding and returns a character stream
- The [UTF-8 decode](#) algorithm which takes a byte stream and returns a character stream, additionally stripping one leading UTF-8 Byte Order Mark (BOM), if any

Note *The [UTF-8 decoder^{p47}](#) is distinct from the [UTF-8 decode algorithm^{p47}](#). The latter first strips a Byte Order Mark (BOM), if any, and then invokes the former.*

For readability, character encodings are sometimes referenced in this specification with a case that differs from the canonical case given in the WHATWG Encoding standard. (For example, "UTF-16LE" instead of "utf-16le".)

XML and related specifications

Implementations that support the [XHTML syntax](#)^{p1054} must support some version of XML, as well as its corresponding namespaces specification, because that syntax uses an XML serialisation with namespaces. [\[XML\]](#)^{p1154} [\[XMLNS\]](#)^{p1154}

The attribute with the tag name `xml:space` in the [XML namespace](#)^{p101} is defined by the XML specification. [\[XML\]](#)^{p1154}

This specification also references the `<?xml-stylesheet?>` processing instruction, defined in the *Associating Style Sheets with XML documents* specification. [\[XMLSSPI\]](#)^{p1154}

This specification also non-normatively mentions the `XSLTProcessor` interface and its `transformToFragment()` and `transformToDocument()` methods.

URLs

The following terms are defined in the WHATWG URL standard: [\[URL\]](#)^{p1153}

- **URL**
- [Origin](#) of URLs
- **Absolute URL**
- **Relative URL**
- **Relative schemes**
- The **URL parser**
- **Parsed URL**
- The **scheme** component of a [parsed URL](#)^{p48}
- The **scheme data** component of a [parsed URL](#)^{p48}
- The **username** component of a [parsed URL](#)^{p48}
- The **password** component of a [parsed URL](#)^{p48}
- The **host** component of a [parsed URL](#)^{p48}
- The **port** component of a [parsed URL](#)^{p48}
- The **path** component of a [parsed URL](#)^{p48}
- The **query** component of a [parsed URL](#)^{p48}
- The **fragment** component of a [parsed URL](#)^{p48}
- **Parse errors** from the [URL parser](#)^{p48}
- The **URL serialiser**
- **Default encode set**
- **Percent encode**
- **UTF-8 percent encode**
- **Percent decode**
- **Decoder error**
- The **domain to ASCII** algorithm
- The **domain to Unicode** algorithm
- [URLUtils](#) interface
- [URLUtilsReadOnly](#) interface
- **href** IDL attribute
- **protocol** IDL attribute
- The **get the base** hook for [URLUtils](#)^{p48}
- The **update steps** hook for [URLUtils](#)^{p48}
- The **set the input** algorithm for [URLUtils](#)^{p48}
- The **query encoding** of an [URLUtils](#)^{p48} object
- The **input** of an [URLUtils](#)^{p48} object
- The **url** of an [URLUtils](#)^{p48} object

Spec bugs: [26400](#), [26402](#)

Spec bugs: [27938](#)

A number of schemes and protocols are referenced by this specification also:

- The **about:** scheme [\[ABOUT\]](#)^{p1148}
- The **blob:** scheme [\[FILEAPI\]](#)^{p1150}
- The **data:** scheme [\[RFC2397\]](#)^{p1152}
- The **http:** scheme [\[HTTP\]](#)^{p1150}
- The **https:** scheme [\[HTTP\]](#)^{p1150}
- The **mailto:** scheme [\[MAILTO\]](#)^{p1151}
- The **sms:** scheme [\[SMS\]](#)^{p1153}
- The **urn:** scheme [\[URN\]](#)^{p1154}

HTTP and related specifications

The following terms are defined in the HTTP specifications: [\[HTTP\]](#)^{p1150}

- **Accept** header

- **Accept-Language** header
- **Cache-Control** header
- **Content-Disposition** header
- **Content-Language** header
- **Content-Length** header
- **Host** header
- **Last-Modified** header
- **Referer** header

The following term is defined in the Web Origin specification: [\[ORIGIN\]^{p1151}](#)

- **Origin** header

The following terms are defined in the Cookie specification: [\[COOKIES\]^{p1148}](#)

- **cookie-string**
- **receives a set-cookie-string**
- **Cookie** header

The following term is defined in the Web Linking specification: [\[WEBLINK\]^{p1154}](#)

- **Link** header

Fetch

The following terms are defined in the WHATWG Fetch specification: [\[FETCH\]^{p1150}](#)

- **cross-origin request**
- **cross-origin request status**
- **custom request headers**
- **simple cross-origin request**
- **redirect steps**
- **omit credentials flag**
- **resource sharing check**

This specification does not yet use the "fetch" algorithm from the WHATWG Fetch specification. It will be updated to do so in due course. Some of the terms mentioned above are obsolete; this will be fixed when the spec is updated to use the new algorithm.

Web IDL

The IDL fragments in this specification must be interpreted as required for conforming IDL fragments, as described in the Web IDL specification. [\[WEBIDL\]^{p1154}](#)

The following terms are defined in the Web IDL specification:

- **Supported property indices**
- **Determine the value of an indexed property**
- **Support named properties**
- **Supported property names**
- **Unenumerable**
- **Determine the value of a named property**
- **Platform array objects**
- **Read only** (when applied to arrays)
- **Callback this value**
- **Converting** between WebIDL types and JS types
- **invoke the Web IDL callback function**

The Web IDL specification also defines the following types that are used in Web IDL fragments in this specification:

- **Array**
- **boolean**
- **Boolean**
- **Date**
- **DOMString**
- **USVString**
- **double**
- **Error**
- **Function**
- **long**
- **Map**
- **Number**
- **Object**
- **RegExp**

- `Set`
- `String`
- `unrestricted double`
- `unsigned long`

The term **throw** in this specification is used as defined in the WebIDL specification. The following exception names are defined by WebIDL and used by this specification:

1. `IndexSizeError`
3. `HierarchyRequestError`
5. `InvalidCharacterError`
8. `NotFoundError`
9. `NotSupportedError`
11. `InvalidStateError`
12. `SyntaxError`
15. `InvalidAccessError`
18. `SecurityError`
19. `NetworkError`
21. `URLMismatchError`
22. `QuotaExceededError`
23. `TimeoutError`
25. `DataCloneError`
26. `TypeError`

When this specification requires a user agent to **create a `Date` object** representing a particular time (which could be the special value `Not-a-Number`), the milliseconds component of that time, if any, must be truncated to an integer, and the time value of the newly created `Date`^{p49} object must represent the resulting truncated time.

Example For instance, given the time 23045 millionths of a second after 01:00 UTC on January 1st 2000, i.e. the time 2000-01-01T00:00:00.023045Z, then the `Date`^{p49} object created representing that time would represent the same time as that created representing the time 2000-01-01T00:00:00.023Z, 45 millionths earlier. If the given time is `Nan`, then the result is a `Date`^{p49} object that represents a time value `Nan` (indicating that the object does not represent a specific instant of time).

JavaScript

Some parts of the language described by this specification only support JavaScript as the underlying scripting language. [ECMA262]^{p1150}

Note *The term "JavaScript" is used to refer to ECMA262, rather than the official term ECMAScript, since the term JavaScript is more widely known. Similarly, the `MIME type`^{p42} used to refer to JavaScript in this specification is `text/javascript`, since that is the most commonly used type, `despite it being an officially obsoleted type`^{p26} according to RFC 4329. [RFC4329]^{p1152}*

The term **JavaScript global environment** refers to the *global environment* concept defined in the ECMAScript specification.

The ECMAScript `SyntaxError` exception is also defined in the ECMAScript specification. [ECMA262]^{p1150}

The **ArrayBuffer** and related object types and underlying concepts from the ECMAScript Specification are used for several features in this specification. [ECMA262]^{p1150} Spec bugs: 27030

The following helper IDL is used for referring to `ArrayBuffer`^{p50}-related types:

```
IDL   typedef (Int8Array or Uint8Array or Uint8ClampedArray or
           Int16Array or Uint16Array or
           Int32Array or Uint32Array or
           Float32Array or Float64Array or
           DataView) ArrayBufferView;
```

Note *In particular, the `Uint8ClampedArray`^{p50} type is used by some `2D canvas APIs`^{p616}, and the `WebSocket API`^{p891} uses `ArrayBuffer`^{p50} objects for handling binary frames.*

DOM

The Document Object Model (DOM) is a representation — a model — of a document and its content. The DOM is not just an API; the conformance criteria of HTML implementations are defined, in this specification, in terms of operations on the DOM. [DOM]^{p1149}

Implementations must support DOM and the events defined in DOM Events, because this specification is defined in terms of the DOM, and some of the features are defined as extensions to the DOM interfaces. [DOM]^{p1149} [DOMEVENTS]^{p1149}

In particular, the following features are defined in the DOM specification: [\[DOM\]^{p1149}](#)

- **Attr** interface
- **Comment** interface
- **DOMImplementation** interface
- **Document** interface
- **XMLElement** interface
- **DocumentFragment** interface
- **DocumentType** interface
- **ChildNode** interface
- **Element** interface
- **Node** interface
- **NodeList** interface
- **ProcessingInstruction** interface
- **Text** interface
- **node document** concept
- **HTMLCollection** interface
- **HTMLCollection.length** attribute
- **HTMLCollection.item()** method
- **HTMLCollection.namedItem()** method
- The terms **collections** and **represented by the collection**
- **DOMTokenList** interface
- **DOMSettableTokenList** interface
- **DOMSettableTokenList.value** attribute
- **createDocument()** method
- **createHTMLDocument()** method
- **createElement()** method
- **createElementNS()** method
- **getElementById()** method
- **getElementsByClassName()** method
- **insertBefore()** method
- **appendChild()** method
- **cloneNode()** method
- **importNode()** method
- **childNodes** attribute
- **localName** attribute
- **parentNode** attribute
- **namespaceURI** attribute
- **tagName** attribute
- **id** attribute
- **textContent** attribute
- The **insert**, **append**, **remove**, **replace**, and **adopt** algorithms for nodes
- The **insertion steps**, **removing steps**, and **adopting steps** hooks
- The **attribute list** concept.
- The **data** of a text node.
- **Event** interface
- **EventTarget** interface
- **EventInit** dictionary type
- **target** attribute
- **currentTarget** attribute
- **isTrusted** attribute
- **initEvent()** method
- **addEventListener()** method
- The **type** of an event
- The concept of an **event listener** and the **event listeners**^{p51} associated with an **EventTarget**^{p51}
- The concept of a **target override**
- The concept of a regular **event parent** and a **cross-boundary event parent**
- The **encoding** (herein the *character encoding*) and **content type** of a **Document**^{p102}
- The distinction between **XML documents** and **HTML documents**
- The terms **quirks mode**, **limited-quirks mode**, and **no-quirks mode**
- The algorithm to **clone** a **Node**^{p51}, and the concept of **cloning steps** used by that algorithm
- The concept of **base URL change steps** and the definition of what happens when an element is **affected by a base URL change**
- The concept of an element's **unique identifier (ID)**
- The concept of a **DOM range**, and the terms **start**, **end**, and **boundary point** as applied to ranges.
- **MutationObserver** interface and **mutation observers** in general
- **Promise** interface
- The **resolver** concept
- The **fulfill** and **reject** algorithms

The following features are defined in the DOM Events specification: [\[DOMEVENTS\]^{p1149}](#)

- **MouseEvent** interface
- The **MouseEvent**^{p51} interface's **relatedTarget** attribute
- **MouseEventInit** dictionary type

- The `FocusEvent` interface
- The `FocusEvent`^{p52} interface's `relatedTarget` attribute
- The `UIEvent` interface
- The `UIEvent` interface's `view` attribute
- The `UIEvent` interface's `detail` attribute
- `click` event
- `dblclick` event
- `mousedown` event
- `mouseenter` event
- `mouseleave` event
- `mousemove` event
- `mouseout` event
- `mouseover` event
- `mouseup` event
- `mousewheel` event
- `keydown` event
- `keyup` event
- `keypress` event

The following features are defined in the Touch Events specification: [\[TOUCH\]](#)^{p1153}

- `Touch` interface
- `Touch point` concept

This specification sometimes uses the term `name` to refer to the event's `type`^{p51}; as in, "an event named `click`" or "if the event name is `keypress`". The terms "name" and "type" for events are synonymous.

The following features are defined in the *DOM Parsing and Serialization* specification: [\[DOMPARSING\]](#)^{p1149}

- `DOMParser`
- `innerHTML`
- `outerHTML`

The `Selection` interface is defined in the *HTML Editing APIs* specification. [\[EDITING\]](#)^{p1150}

Note *User agents are encouraged to implement the features described in the *HTML Editing APIs* specification.* [\[EDITING\]](#)^{p1150}

The following parts of the Fullscreen specification are referenced from this specification, in part to define the rendering of `dialog`^{p586} elements, and also to define how the Fullscreen API interacts with the sandboxing features in HTML: [\[FULLSCREEN\]](#)^{p1150}

- The `top layer` concept
- `requestFullscreen()`
- The `fullscreen enabled` flag
- The `fully exit fullscreen` algorithm

The *High Resolution Time* specification provides the `Performance` object's `now()` method. [\[HRT\]](#)^{p1150}

File API

This specification uses the following features defined in the File API specification: [\[FILEAPI\]](#)^{p1150}

- `Blob` interface
- `File` interface
- `FileList` interface
- `Blob.close()`
- `Blob.type`
- The concept of `read errors`

Media Providers

This specification references the following interfaces:

- `MediaStream` [\[MEDIASTREAM\]](#)^{p1151}
- `MediaSource` [\[MEDIASOURCE\]](#)^{p1151}

XMLHttpRequest

This specification references the XMLHttpRequest specification to describe how the two specifications interact and to use its `ProgressEvent`^{p52} features. The following features and terms are defined in the XMLHttpRequest specification: [\[XHR\]](#)^{p1154}

- `XMLHttpRequest` interface
- `XMLHttpRequest.responseXML` attribute
- `ProgressEvent` interface

- `ProgressEvent.lengthComputable` attribute
- `ProgressEvent.loaded` attribute
- `ProgressEvent.total` attribute
- Fire a progress event named `e`

Media Queries

Implementations must support the Media Queries language. [\[MQ\]^{p1151}](#)

CSS modules

While support for CSS as a whole is not required of implementations of this specification (though it is encouraged, at least for Web browsers), some features are defined in terms of specific CSS requirements.

When this specification requires that something be [parsed according to a particular CSS grammar](#), the relevant algorithm in the CSS Syntax specification must be followed. [\[CSSSYNTAX\]^{p1149}](#)

In particular, some features require that a string be [parsed as a CSS <color> value](#). When parsing a CSS value, user agents are required by the CSS specifications to apply some error handling rules. These apply to this specification also. [\[CSSCOLOR\]^{p1149}](#) [\[CSS\]^{p1149}](#)

Example For example, user agents are required to close all open constructs upon finding the end of a style sheet unexpectedly. Thus, when parsing the string "`rgb(0, 0, 0)`" (with a missing close-parenthesis) for a colour value, the close parenthesis is implied by this error handling rule, and a value is obtained (the colour 'black'). However, the similar construct "`rgb(0, 0,`" (with both a missing parenthesis and a missing "blue" value) cannot be parsed, as closing the open construct does not result in a viable value.

The term [named colour](#) is defined in the CSS Color specification. [\[CSSCOLOR\]^{p1149}](#)

The term **CSS element reference identifier** is used as defined in the *CSS Image Values and Replaced Content* specification to define the API that declares identifiers for use with the CSS 'element()' function. [\[CSSIMAGES\]^{p1149}](#)

Similarly, the term **provides a paint source** is used as defined in the *CSS Image Values and Replaced Content* specification to define the interaction of certain HTML elements with the CSS 'element()' function. [\[CSSIMAGES\]^{p1149}](#)

The term **default object size** is also defined in the *CSS Image Values and Replaced Content* specification. [\[CSSIMAGES\]^{p1149}](#)

Implementations that support scripting must support the CSS Object Model. The following features and terms are defined in the CSSOM specifications: [\[CSSOM\]^{p1149}](#) [\[CSSOMVIEW\]^{p1149}](#)

- `Screen` interface
- `LinkStyle` interface
- `CSSStyleDeclaration` interface
- `cssText` attribute of [CSSStyleDeclaration](#)^{b53}
- `StyleSheet` interface
- The terms **create a CSS style sheet**, **remove a CSS style sheet**, and **associated CSS style sheet**
- **CSS style sheets** and their properties: type, location, parent CSS style sheet, owner node, owner CSS rule, media, title, alternate flag, disabled flag, CSS rules, origin-clean flag
- **Alternative style sheet sets** and the **preferred style sheet set**
- Serialising a CSS value
- Scroll an element into view
- Scroll to the beginning of the document
- The `resize` event
- The `scroll` event
- [The features argument of window.open](#)

The term **environment encoding** is defined in the CSS Syntax specifications. [\[CSSSYNTAX\]^{p1149}](#)

The term **CSS styling attribute** is defined in the CSS Style Attributes specification. [\[CSSATTR\]^{p1149}](#)

The [CanvasRenderingContext2D](#)^{b613} object's use of fonts depends on the features described in the CSS Fonts and Font Loading specifications, including in particular `FontFace` objects and the `font source` concept. [\[CSSFONTS\]^{p1149}](#) [\[CSSFONTLOAD\]^{p1149}](#)

SVG

The following interface is defined in the SVG specification: [\[SVG\]^{p1153}](#)

- `SVGMatrix` interface

WebGL

The following interface is defined in the WebGL specification: [\[WEBGL\]^{p1154}](#)

- [WebGLRenderingContext](#) interface

WebVTT

Implementations may support WebVTT as a text track format for subtitles, captions, chapter titles, metadata, etc, for media resources.

[\[WEBVTT\]^{p1154}](#)

The following terms, used in this specification, are defined in the WebVTT specification:

- [WebVTT file](#)
- [WebVTT file using cue text](#)
- [WebVTT file using chapter title text](#)
- [WebVTT file using only nested cues](#)
- [WebVTT parser](#)
- [The rules for updating the display of WebVTT text tracks](#)
- [The rules for interpreting WebVTT cue text](#)
- [The WebVTT text track cue writing direction](#)
- [VTTcue](#) interface

The WebSocket protocol

The following terms are defined in the WebSocket protocol specification: [\[WSP\]^{p1154}](#)

- [establish a WebSocket connection](#)
- [the WebSocket connection is established](#)
- [validate the server's response](#)
- [extensions in use](#)
- [subprotocol in use](#)
- [headers to send appropriate cookies](#)
- [cookies set during the server's opening handshake](#)
- [a WebSocket message has been received](#)
- [send a WebSocket Message](#)
- [fail the WebSocket connection](#)
- [close the WebSocket connection](#)
- [start the WebSocket closing handshake](#)
- [the WebSocket closing handshake is started](#)
- [the WebSocket connection is closed \(possibly cleanly\)](#)
- [the WebSocket connection close code](#)
- [the WebSocket connection close reason](#)
- [Sec-WebSocket-Protocol](#) field

ARIA

The terms [strong native semantics](#) is used as defined in the ARIA specification. The term [default implicit ARIA semantics](#) has the same meaning as the term [implicit WAI-ARIA semantics](#) as used in the ARIA specification. [\[ARIA\]^{p1148}](#)

The [role](#) attribute is defined in the ARIA specification, as are the following roles: [\[ARIA\]^{p1148}](#)

- [alert](#)
- [alertdialog](#)
- [application](#)
- [article](#)
- [banner](#)
- [button](#)
- [checkbox](#)
- [columnheader](#)
- [combobox](#)
- [complementary](#)
- [contentinfo](#)
- [dialog](#)
- [directory](#)
- [document](#)
- [grid](#)
- [gridcell](#)
- [group](#)
- [heading](#)
- [img](#)
- [link](#)
- [list](#)
- [listbox](#)
- [listitem](#)
- [log](#)
- [main](#)
- [marquee](#)
- [menu](#)
- [menubar](#)
- [menuitem](#)

- [menuitemcheckbox](#)
- [menuitemradio](#)
- [navigation](#)
- [note](#)
- [option](#)
- [presentation](#)
- [progressbar](#)
- [radio](#)
- [region](#)
- [row](#)
- [rowgroup](#)
- [rowheader](#)
- [search](#)
- [separator](#)
- [slider](#)
- [spinbutton](#)
- [status](#)
- [tab](#)
- [tablist](#)
- [textbox](#)
- [toolbar](#)
- [tree](#)
- [treeitem](#)

In addition, the following `aria-`* content attributes are defined in the ARIA specification: [\[ARIA\]](#)^{p1148}

- [aria-checked](#)
- [aria-describedby](#)
- [aria-disabled](#)
- [aria-expanded](#)
- [aria-hidden](#)
- [aria-invalid](#)
- [aria-label](#)
- [aria-level](#)
- [aria-multiline](#)
- [aria-multiselectable](#)
- [aria-owns](#)
- [aria-readonly](#)
- [aria-required](#)
- [aria-selected](#)
- [aria-sort](#)
- [aria-valuemax](#)
- [aria-valuemin](#)
- [aria-valuenow](#)

This specification does not *require* support of any particular network protocol, style sheet language, scripting language, or any of the DOM specifications beyond those required in the list above. However, the language described by this specification is biased towards CSS as the styling language, JavaScript as the scripting language, and HTTP as the network protocol, and several features assume that those languages and protocols are in use.

A user agent that implements the HTTP protocol must implement the Web Origin Concept specification and the HTTP State Management Mechanism specification (Cookies) as well. [\[HTTP\]](#)^{p1150} [\[ORIGIN\]](#)^{p1151} [\[COOKIES\]](#)^{p1148}

Note This specification might have certain additional requirements on character encodings, image formats, audio formats, and video formats in the respective sections.

2.2.3 Extensibility

Vendor-specific proprietary user agent extensions to this specification are strongly discouraged. Documents must not use such extensions, as doing so reduces interoperability and fragments the user base, allowing only users of specific user agents to access the content in question.

If such extensions are nonetheless needed, e.g. for experimental purposes, then vendors are strongly urged to use one of the following extension mechanisms:

- For markup-level features that can be limited to the XML serialisation and need not be supported in the HTML serialisation, vendors should use the namespace mechanism to define custom namespaces in which the non-standard elements and attributes are supported.

- For markup-level features that are intended for use with [the HTML syntax](#)^{p941}, extensions should be limited to new attributes of the form "`x-vendor-feature`", where `vendor` is a short string that identifies the vendor responsible for the extension, and `feature` is the name of the feature. New element names should not be created. Using attributes for such extensions exclusively allows extensions from multiple vendors to co-exist on the same element, which would not be possible with elements. Using the "`x-vendor-feature`" form allows extensions to be made without risk of conflicting with future additions to the specification.

Example

For instance, a browser named "FerretBrowser" could use "ferret" as a vendor prefix, while a browser named "Mellblom Browser" could use "mb". If both of these browsers invented extensions that turned elements into scratch-and-sniff areas, an author experimenting with these features could write:

```
<p>This smells of lemons!
<span x-ferret-smellovision x-ferret-smellcode="LEM01"
      x-mb-outputsmeill x-mb-smell="lemon juice"></span></p>
```

Attribute names beginning with the two characters "`x-`" are reserved for user agent use and are guaranteed to never be formally added to the HTML language. For flexibility, attributes names containing underscores (the U+005F LOW LINE character) are also reserved for experimental purposes and are guaranteed to never be formally added to the HTML language.

Note *Pages that use such attributes are by definition non-conforming.*

For DOM extensions, e.g. new methods and IDL attributes, the new members should be prefixed by vendor-specific strings to prevent clashes with future versions of this specification.

For events, experimental event types should be prefixed with vendor-specific strings.

Example

For example, if a user agent called "Pleasold" were to add an event to indicate when the user is going up in an elevator, it could use the prefix "`pleasold`" and thus name the event "`pleasoldgoingup`", possibly with an event handler attribute named "`onpleasoldgoingup`".

All extensions must be defined so that the use of extensions neither contradicts nor causes the non-conformance of functionality defined in the specification.

Example

For example, while strongly discouraged from doing so, an implementation "Foo Browser" could add a new IDL attribute "`fooTypeTime`" to a control's DOM interface that returned the time it took the user to select the current value of a control (say). On the other hand, defining a new control that appears in a form's [elements](#)^{p449} array would be in violation of the above requirement, as it would violate the definition of [elements](#)^{p449} given in this specification.

When adding new [reflecting](#)^{p88} IDL attributes corresponding to content attributes of the form "`x-vendor-feature`", the IDL attribute should be named "`vendorFeature`" (i.e. the "`x`" is dropped from the IDL attribute's name).

When vendor-neutral extensions to this specification are needed, either this specification can be updated accordingly, or an extension specification can be written that overrides the requirements in this specification. When someone applying this specification to their activities decides that they will recognise the requirements of such an extension specification, it becomes an **applicable specification** for the purposes of conformance requirements in this specification.

Note

Someone could write a specification that defines any arbitrary byte stream as conforming, and then claim that their random junk is conforming. However, that does not mean that their random junk actually is conforming for everyone's purposes: if someone else decides that that specification does not apply to their work, then they can quite legitimately say that the aforementioned random junk is just that, junk, and not conforming at all. As far as conformance goes, what matters in a particular community is what that community agrees is applicable.

User agents must treat elements and attributes that they do not understand as semantically neutral; leaving them in the DOM (for DOM processors), and styling them according to CSS (for CSS processors), but not inferring any meaning from them.

When support for a feature is disabled (e.g. as an emergency measure to mitigate a security problem, or to aid in development, or for performance reasons), user agents must act as if they had no support for the feature whatsoever, and as if the feature was not mentioned in this specification.

For example, if a particular feature is accessed via an attribute in a Web IDL interface, the attribute itself would be omitted from the objects that implement that interface — leaving the attribute on the object but making it return null or throw an exception is insufficient.

Spec bugs: [18460](#)

2.2.4 Interactions with XPath and XSLT

Implementations of XPath 1.0 that operate on [HTML documents](#)^{p51} parsed or created in the manners described in this specification (e.g. as part of the `document.evaluate()` API) must act as if the following edit was applied to the XPath 1.0 specification.

First, remove this paragraph:

A [QName](#) in the node test is expanded into an [expanded-name](#) using the namespace declarations from the expression context. This is the same way expansion is done for element type names in start and end-tags except that the default namespace declared with `xmlns` is not used: if the [QName](#) does not have a prefix, then the namespace URI is null (this is the same way attribute names are expanded). It is an error if the [QName](#) has a prefix for which there is no namespace declaration in the expression context.

Then, insert in its place the following:

A QName in the node test is expanded into an expanded-name using the namespace declarations from the expression context. If the QName has a prefix, then there must be a namespace declaration for this prefix in the expression context, and the corresponding namespace URI is the one that is associated with this prefix. It is an error if the QName has a prefix for which there is no namespace declaration in the expression context.

If the QName has no prefix and the principal node type of the axis is `element`, then the default element namespace is used. Otherwise if the QName has no prefix, the namespace URI is null. The default element namespace is a member of the context for the XPath expression. The value of the default element namespace when executing an XPath expression through the DOM3 XPath API is determined in the following way:

1. If the context node is from an HTML DOM, the default element namespace is "<http://www.w3.org/1999/xhtml>".
2. Otherwise, the default element namespace URI is null.

Note This is equivalent to adding the default element namespace feature of XPath 2.0 to XPath 1.0, and using the HTML namespace as the default element namespace for HTML documents. It is motivated by the desire to have implementations be compatible with legacy HTML content while still supporting the changes that this specification introduces to HTML regarding the namespace used for HTML elements, and by the desire to use XPath 1.0 rather than XPath 2.0.

Note This change is a [willful violation](#)^{p26} of the XPath 1.0 specification, motivated by desire to have implementations be compatible with legacy content while still supporting the changes that this specification introduces to HTML regarding which namespace is used for HTML elements. [\[XPATH10\]^{p154}](#)

XSLT 1.0 processors outputting to a DOM when the output method is "html" (either explicitly or via the defaulting rule in XSLT 1.0) are affected as follows:

If the transformation program outputs an element in no namespace, the processor must, prior to constructing the corresponding DOM element node, change the namespace of the element to the [HTML namespace](#)^{p101}, [ASCII-lowercase](#)^{p58} the element's local name, and [ASCII-lowercase](#)^{p58} the names of any non-namespaced attributes on the element.

Note This requirement is a [willful violation](#)^{p26} of the XSLT 1.0 specification, required because this specification changes the namespaces and case-sensitivity rules of HTML in a manner that would otherwise be incompatible with DOM-based XSLT transformations. (Processors that serialise the output are unaffected.) [\[XSLT10\]^{p154}](#)

This specification does not specify precisely how XSLT processing interacts with the [HTML parser](#)^{p952} infrastructure (for example, whether an XSLT processor acts as if it puts any elements into a [stack of open elements](#)^{p962}). However, XSLT processors must [stop parsing](#)^{p1033} if they successfully complete, and must set the [current document readiness](#)^{p105} first to "interactive" and then to "complete" if they are aborted.

This specification does not specify how XSLT interacts with the [navigation](#)^{p791} algorithm, how it fits in with the [event loop](#)^{p834}, nor how error pages are to be handled (e.g. whether XSLT errors are to replace an incremental XSLT output, or are rendered inline, etc).

Note There are also additional non-normative comments regarding the interaction of XSLT and HTML in the [script element section^{p602}](#), and of XSLT, XPath, and HTML in the [template element section^{p607}](#).

2.3 Case-sensitivity and string comparison

Comparing two strings in a **case-sensitive** manner means comparing them exactly, code point for code point.

Comparing two strings in an **ASCII case-insensitive** manner means comparing them exactly, code point for code point, except that the characters in the range U+0041 to U+005A (i.e. LATIN CAPITAL LETTER A to LATIN CAPITAL LETTER Z) and the corresponding characters in the range U+0061 to U+007A (i.e. LATIN SMALL LETTER A to LATIN SMALL LETTER Z) are considered to also match.

Comparing two strings in a **compatibility caseless** manner means using the Unicode *compatibility caseless match* operation to compare the two strings, with no language-specific tailoring. [\[UNICODE\]^{p153}](#)

Except where otherwise stated, string comparisons must be performed in a [case-sensitive^{p58}](#) manner.

Converting a string to ASCII uppercase means replacing all characters in the range U+0061 to U+007A (i.e. LATIN SMALL LETTER A to LATIN SMALL LETTER Z) with the corresponding characters in the range U+0041 to U+005A (i.e. LATIN CAPITAL LETTER A to LATIN CAPITAL LETTER Z).

Converting a string to ASCII lowercase means replacing all characters in the range U+0041 to U+005A (i.e. LATIN CAPITAL LETTER A to LATIN CAPITAL LETTER Z) with the corresponding characters in the range U+0061 to U+007A (i.e. LATIN SMALL LETTER A to LATIN SMALL LETTER Z).

A string *pattern* is a **prefix match** for a string *s* when *pattern* is not longer than *s* and truncating *s* to *pattern*'s length leaves the two strings as matches of each other.

2.4 Common microsyntaxes

There are various places in HTML that accept particular data types, such as dates or numbers. This section describes what the conformance criteria for content in those formats is, and how to parse them.

Note Implementors are strongly urged to carefully examine any third-party libraries they might consider using to implement the parsing of syntaxes described below. For example, date libraries are likely to implement error handling behaviour that differs from what is required in this specification, since error-handling behaviour is often not defined in specifications that describe date syntaxes similar to those used in this specification, and thus implementations tend to vary greatly in how they handle errors.

2.4.1 Common parser idioms

The **space characters**, for the purposes of this specification, are U+0020 SPACE, U+0009 CHARACTER TABULATION (tab), U+000A LINE FEED (LF), U+000C FORM FEED (FF), and U+000D CARRIAGE RETURN (CR).

The **White_Space characters** are those that have the Unicode property "White_Space" in the Unicode PropList.txt data file. [\[UNICODE\]^{p153}](#)

Note This should not be confused with the "White_Space" value (abbreviated "WS") of the "Bidi_Class" property in the Unicode.txt data file.

The **control characters** are those whose Unicode "General_Category" property has the value "Cc" in the Unicode UnicodeData.txt data file. [\[UNICODE\]^{p153}](#)

The **uppercase ASCII letters** are the characters in the range U+0041 LATIN CAPITAL LETTER A to U+005A LATIN CAPITAL LETTER Z.

The **lowercase ASCII letters** are the characters in the range U+0061 LATIN SMALL LETTER A to U+007A LATIN SMALL LETTER Z.

The **ASCII digits** are the characters in the range U+0030 DIGIT ZERO (0) to U+0039 DIGIT NINE (9).

The **alphanumeric ASCII characters** are those that are either [uppercase ASCII letters^{p58}](#), [lowercase ASCII letters^{p58}](#), or [ASCII digits^{p58}](#).

The **ASCII hex digits** are the characters in the ranges U+0030 DIGIT ZERO (0) to U+0039 DIGIT NINE (9), U+0041 LATIN CAPITAL LETTER A to U+0046 LATIN CAPITAL LETTER F, and U+0061 LATIN SMALL LETTER A to U+0066 LATIN SMALL LETTER F.

The **uppercase ASCII hex digits** are the characters in the ranges U+0030 DIGIT ZERO (0) to U+0039 DIGIT NINE (9) and U+0041 LATIN CAPITAL LETTER A to U+0046 LATIN CAPITAL LETTER F only.

The **lowercase ASCII hex digits** are the characters in the ranges U+0030 DIGIT ZERO (0) to U+0039 DIGIT NINE (9) and U+0061 LATIN SMALL LETTER A to U+0066 LATIN SMALL LETTER F only.

Some of the micro-parsers described below follow the pattern of having an *input* variable that holds the string being parsed, and having a *position* variable pointing at the next character to parse in *input*.

For parsers based on this pattern, a step that requires the user agent to **collect a sequence of characters** means that the following algorithm must be run, with *characters* being the set of characters that can be collected:

1. Let *input* and *position* be the same variables as those of the same name in the algorithm that invoked these steps.
2. Let *result* be the empty string.
3. While *position* doesn't point past the end of *input* and the character at *position* is one of the *characters*, append that character to the end of *result* and advance *position* to the next character in *input*.
4. Return *result*.

The step **skip whitespace** means that the user agent must [collect a sequence of characters^{p59}](#) that are [space characters^{p58}](#). The collected characters are not used.

When a user agent is to **strip line breaks** from a string, the user agent must remove any U+000A LINE FEED (LF) and U+000D CARRIAGE RETURN (CR) characters from that string.

When a user agent is to **strip leading and trailing whitespace** from a string, the user agent must remove all [space characters^{p58}](#) that are at the start or end of the string.

When a user agent is to **strip and collapse whitespace** in a string, it must replace any sequence of one or more consecutive [space characters^{p58}](#) in that string with a single U+0020 SPACE character, and then [strip leading and trailing whitespace^{p59}](#) from that string.

When a user agent has to **strictly split a string** on a particular delimiter character *delimiter*, it must use the following algorithm:

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Let *tokens* be an ordered list of tokens, initially empty.
4. While *position* is not past the end of *input*:
 1. [Collect a sequence of characters^{p59}](#) that are not the *delimiter* character.
 2. Append the string collected in the previous step to *tokens*.
 3. Advance *position* to the next character in *input*.
5. Return *tokens*.

Note *For the special cases of splitting a string on spaces^{p80} and on commas^{p81}, this algorithm does not apply (those algorithms also perform whitespace trimming^{p59}).*

2.4.2 Boolean attributes

A number of attributes are **boolean attributes**. The presence of a boolean attribute on an element represents the true value, and the absence of the attribute represents the false value.

If the attribute is present, its value must either be the empty string or a value that is an [ASCII case-insensitive^{p58}](#) match for the attribute's canonical name, with no leading or trailing whitespace.

Note *The values "true" and "false" are not allowed on boolean attributes. To represent a false value, the attribute has to be omitted altogether.*

Example

Here is an example of a checkbox that is checked and disabled. The `checked`^{p457} and `disabled`^{p530} attributes are the boolean attributes.

```
<label><input type=checkbox checked name=cheese disabled> Cheese</label>
```

This could be equivalently written as this:

```
<label><input type=checkbox checked=checked name=cheese disabled=disabled> Cheese</label>
```

You can also mix styles; the following is still equivalent:

```
<label><input type='checkbox' checked name=cheese disabled=""> Cheese</label>
```

2.4.3 Keywords and enumerated attributes

Some attributes are defined as taking one of a finite set of keywords. Such attributes are called **enumerated attributes**. The keywords are each defined to map to a particular *state* (several keywords might map to the same state, in which case some of the keywords are synonyms of each other; additionally, some of the keywords can be said to be non-conforming, and are only in the specification for historical reasons). In addition, two default states can be given. The first is the **invalid value default**, the second is the **missing value default**.

If an enumerated attribute is specified, the attribute's value must be an [ASCII case-insensitive^{p58}](#) match for one of the given keywords that are not said to be non-conforming, with no leading or trailing whitespace.

When the attribute is specified, if its value is an [ASCII case-insensitive^{p58}](#) match for one of the given keywords then that keyword's state is the state that the attribute represents. If the attribute value matches none of the given keywords, but the attribute has an [invalid value default^{p60}](#), then the attribute represents that state. Otherwise, if the attribute value matches none of the keywords but there is a [missing value default^{p60}](#) state defined, then *that* is the state represented by the attribute. Otherwise, there is no default, and invalid values mean that there is no state represented.

When the attribute is *not* specified, if there is a [missing value default^{p60}](#) state defined, then that is the state represented by the (missing) attribute. Otherwise, the absence of the attribute means that there is no state represented.

Note *The empty string can be a valid keyword.*

2.4.4 Numbers

2.4.4.1 Signed integers

A string is a **valid integer** if it consists of one or more [ASCII digits^{p58}](#), optionally prefixed with a U+002D HYPHEN-MINUS character (-).

A [valid integer^{p60}](#) without a U+002D HYPHEN-MINUS (-) prefix represents the number that is represented in base ten by that string of digits. A [valid integer^{p60}](#) with a U+002D HYPHEN-MINUS (-) prefix represents the number represented in base ten by the string of digits that follows the U+002D HYPHEN-MINUS, subtracted from zero.

The **rules for parsing integers** are as given in the following algorithm. When invoked, the steps must be followed in the order given, aborting at the first step that returns a value. This algorithm will return either an integer or an error.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Let *sign* have the value "positive".
4. [Skip whitespace^{p59}](#).

5. If *position* is past the end of *input*, return an error.
6. If the character indicated by *position* (the first character) is a U+002D HYPHEN-MINUS character (-):
 1. Let *sign* be "negative".
 2. Advance *position* to the next character.
 3. If *position* is past the end of *input*, return an error.

Otherwise, if the character indicated by *position* (the first character) is a U+002B PLUS SIGN character (+):

1. Advance *position* to the next character. (The "+" is ignored, but it is not conforming.)
2. If *position* is past the end of *input*, return an error.
7. If the character indicated by *position* is not an [ASCII digit^{p58}](#), then return an error.
8. [Collect a sequence of characters^{p59}](#) that are [ASCII digits^{p58}](#), and interpret the resulting sequence as a base-ten integer. Let *value* be that integer.
9. If *sign* is "positive", return *value*, otherwise return the result of subtracting *value* from zero.

2.4.4.2 Non-negative integers

A string is a **valid non-negative integer** if it consists of one or more [ASCII digits^{p58}](#).

A [valid non-negative integer^{p61}](#) represents the number that is represented in base ten by that string of digits.

The **rules for parsing non-negative integers** are as given in the following algorithm. When invoked, the steps must be followed in the order given, aborting at the first step that returns a value. This algorithm will return either zero, a positive integer, or an error.

1. Let *input* be the string being parsed.
2. Let *value* be the result of parsing *input* using the [rules for parsing integers^{p60}](#).
3. If *value* is an error, return an error.
4. If *value* is less than zero, return an error.
5. Return *value*.

2.4.4.3 Floating-point numbers

Spec bugs: [27855](#) :

A string is a **valid floating-point number** if it consists of:

1. Optionally, a U+002D HYPHEN-MINUS character (-).
2. One or both of the following, in the given order:
 1. A series of one or more [ASCII digits^{p58}](#).
 2. 1. A single U+002E FULL STOP character (.).
 2. A series of one or more [ASCII digits^{p58}](#).
3. Optionally:
 1. Either a U+0065 LATIN SMALL LETTER E character (e) or a U+0045 LATIN CAPITAL LETTER E character (E).
 2. Optionally, a U+002D HYPHEN-MINUS character (-) or U+002B PLUS SIGN character (+).
 3. A series of one or more [ASCII digits^{p58}](#).

A [valid floating-point number^{p61}](#) represents the number obtained by multiplying the significand by ten raised to the power of the exponent, where the significand is the first number, interpreted as base ten (including the decimal point and the number after the decimal point, if any, and interpreting the significand as a negative number if the whole string starts with a U+002D HYPHEN-MINUS character (-) and the number is not zero), and where the exponent is the number after the E, if any (interpreted as a negative number if there is a U+002D HYPHEN-MINUS character (-) between the E and the number and the number is not zero, or else ignoring a U+002B PLUS SIGN character (+) between the E and the number if there is one). If there is no E, then the exponent is treated as zero.

Note The Infinity and Not-a-Number (NaN) values are not [valid floating-point numbers^{p61}](#).

The **best representation of the number n as a floating-point number** is the string obtained from applying the JavaScript operator `ToString` to n . The JavaScript operator `ToString` is not uniquely determined. When there are multiple possible strings that could be obtained from the JavaScript operator `ToString` for a particular value, the user agent must always return the same string for that value (though it may differ from the value used by other user agents).

The **rules for parsing floating-point number values** are as given in the following algorithm. This algorithm must be aborted at the first step that returns something. This algorithm will return either a number or an error.

1. Let $input$ be the string being parsed.
2. Let $position$ be a pointer into $input$, initially pointing at the start of the string.
3. Let $value$ have the value 1.
4. Let $divisor$ have the value 1.
5. Let $exponent$ have the value 1.
6. [Skip whitespace^{b59}](#).
7. If $position$ is past the end of $input$, return an error.
8. If the character indicated by $position$ is a U+002D HYPHEN-MINUS character (-):
 1. Change $value$ and $divisor$ to -1.
 2. Advance $position$ to the next character.
 3. If $position$ is past the end of $input$, return an error.

Otherwise, if the character indicated by $position$ (the first character) is a U+002B PLUS SIGN character (+):

1. Advance $position$ to the next character. (The "+" is ignored, but it is not conforming.)
2. If $position$ is past the end of $input$, return an error.
9. If the character indicated by $position$ is a U+002E FULL STOP (.), and that is not the last character in $input$, and the character after the character indicated by $position$ is an [ASCII digit^{b58}](#), then set $value$ to zero and jump to the step labeled *fraction*.
10. If the character indicated by $position$ is not an [ASCII digit^{b58}](#), then return an error.
11. [Collect a sequence of characters^{b59}](#) that are [ASCII digits^{b58}](#), and interpret the resulting sequence as a base-ten integer. Multiply $value$ by that integer.
12. If $position$ is past the end of $input$, jump to the step labeled *conversion*.
13. *Fraction*: If the character indicated by $position$ is a U+002E FULL STOP (.), run these substeps:
 1. Advance $position$ to the next character.
 2. If $position$ is past the end of $input$, or if the character indicated by $position$ is not an [ASCII digit^{b58}](#), U+0065 LATIN SMALL LETTER E (e), or U+0045 LATIN CAPITAL LETTER E (E), then jump to the step labeled *conversion*.
 3. If the character indicated by $position$ is a U+0065 LATIN SMALL LETTER E character (e) or a U+0045 LATIN CAPITAL LETTER E character (E), skip the remainder of these substeps.
 4. *Fraction loop*: Multiply $divisor$ by ten.
 5. Add the value of the character indicated by $position$, interpreted as a base-ten digit (0..9) and divided by $divisor$, to $value$.
 6. Advance $position$ to the next character.
 7. If $position$ is past the end of $input$, then jump to the step labeled *conversion*.
 8. If the character indicated by $position$ is an [ASCII digit^{b58}](#), jump back to the step labeled *fraction loop* in these substeps.
14. If the character indicated by $position$ is a U+0065 LATIN SMALL LETTER E character (e) or a U+0045 LATIN CAPITAL LETTER E character (E), run these substeps:
 1. Advance $position$ to the next character.

2. If *position* is past the end of *input*, then jump to the step labeled *conversion*.
3. If the character indicated by *position* is a U+002D HYPHEN-MINUS character (-):
 1. Change *exponent* to -1.
 2. Advance *position* to the next character.
 3. If *position* is past the end of *input*, then jump to the step labeled *conversion*.

Otherwise, if the character indicated by *position* is a U+002B PLUS SIGN character (+):

1. Advance *position* to the next character.
2. If *position* is past the end of *input*, then jump to the step labeled *conversion*.
4. If the character indicated by *position* is not an [ASCII digit](#)^{p58}, then jump to the step labeled *conversion*.
5. [Collect a sequence of characters](#)^{p59} that are [ASCII digits](#)^{p58}, and interpret the resulting sequence as a base-ten integer. Multiply *exponent* by that integer.
6. Multiply *value* by ten raised to the *exponent*th power.
15. *Conversion*: Let *S* be the set of finite IEEE 754 double-precision floating-point values except -0, but with two special values added: 2^{1024} and -2^{1024} .
16. Let *rounded-value* be the number in *S* that is closest to *value*, selecting the number with an even significand if there are two equally close values. (The two special values 2^{1024} and -2^{1024} are considered to have even significands for this purpose.)
17. If *rounded-value* is 2^{1024} or -2^{1024} , return an error.
18. Return *rounded-value*.

2.4.4.4 Percentages and lengths

The **rules for parsing dimension values** are as given in the following algorithm. When invoked, the steps must be followed in the order given, aborting at the first step that returns a value. This algorithm will return either a number greater than or equal to 1.0, or an error; if a number is returned, then it is further categorised as either a percentage or a length.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. [Skip whitespace](#)^{b59}.
4. If *position* is past the end of *input*, return an error.
5. If the character indicated by *position* is a U+002B PLUS SIGN character (+), advance *position* to the next character.
6. [Collect a sequence of characters](#)^{p59} that are U+0030 DIGIT ZERO (0) characters, and discard them.
7. If *position* is past the end of *input*, return an error.
8. If the character indicated by *position* is not one of U+0031 DIGIT ONE (1) to U+0039 DIGIT NINE (9), then return an error.
9. [Collect a sequence of characters](#)^{p59} that are [ASCII digits](#)^{p58}, and interpret the resulting sequence as a base-ten integer. Let *value* be that number.
10. If *position* is past the end of *input*, return *value* as a length.
11. If the character indicated by *position* is a U+002E FULL STOP character (.):
 1. Advance *position* to the next character.
 2. If *position* is past the end of *input*, or if the character indicated by *position* is not an [ASCII digit](#)^{p58}, then return *value* as a length.

3. Let *divisor* have the value 1.
4. *Fraction loop*: Multiply *divisor* by ten.
5. Add the value of the character indicated by *position*, interpreted as a base-ten digit (0..9) and divided by *divisor*, to *value*.
6. Advance *position* to the next character.
7. If *position* is past the end of *input*, then return *value* as a length.
8. If the character indicated by *position* is an [ASCII digit](#)^{p58}, return to the step labeled *fraction loop* in these substeps.
12. If *position* is past the end of *input*, return *value* as a length.
13. If the character indicated by *position* is a U+0025 PERCENT SIGN character (%), return *value* as a percentage.
14. Return *value* as a length.

2.4.4.5 Lists of integers

A **valid list of integers** is a number of [valid integers](#)^{p60} separated by U+002C COMMA characters, with no other characters (e.g. no [space characters](#)^{p58}). In addition, there might be restrictions on the number of integers that can be given, or on the range of values allowed.

The **rules for parsing a list of integers** are as follows:

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Let *numbers* be an initially empty list of integers. This list will be the result of this algorithm.
4. If there is a character in the string *input* at position *position*, and it is either a U+0020 SPACE, U+002C COMMA, or U+003B SEMICOLON character, then advance *position* to the next character in *input*, or to beyond the end of the string if there are no more characters.
5. If *position* points to beyond the end of *input*, return *numbers* and abort.
6. If the character in the string *input* at position *position* is a U+0020 SPACE, U+002C COMMA, or U+003B SEMICOLON character, then return to step 4.
7. Let *negated* be false.
8. Let *value* be 0.
9. Let *started* be false. This variable is set to true when the parser sees a number or a U+002D HYPHEN-MINUS character (-).
10. Let *got number* be false. This variable is set to true when the parser sees a number.
11. Let *finished* be false. This variable is set to true to switch parser into a mode where it ignores characters until the next separator.
12. Let *bogus* be false.
13. *Parser*: If the character in the string *input* at position *position* is:

↪ **A U+002D HYPHEN-MINUS character**

Follow these substeps:

1. If *got number* is true, let *finished* be true.
2. If *finished* is true, skip to the next step in the overall set of steps.
3. If *started* is true, let *negated* be false.
4. Otherwise, if *started* is false and if *bogus* is false, let *negated* be true.
5. Let *started* be true.

↪ An [ASCII digit](#)^{p58}

Follow these substeps:

1. If *finished* is true, skip to the next step in the overall set of steps.
2. Multiply *value* by ten.
3. Add the value of the digit, interpreted in base ten, to *value*.
4. Let *started* be true.
5. Let *got number* be true.

↪ A U+0020 SPACE character

↪ A U+002C COMMA character

↪ A U+003B SEMICOLON character

Follow these substeps:

1. If *got number* is false, return the *numbers* list and abort. This happens if an entry in the list has no digits, as in "1, 2, x, 4".
2. If *negated* is true, then negate *value*.
3. Append *value* to the *numbers* list.
4. Jump to step 4 in the overall set of steps.

↪ A character in the range U+0001 to U+001F, U+0021 to U+002B, U+002D to U+002F, U+003A, U+003C to U+0040, U+005B to U+0060, U+007b to U+007F (i.e. any other non-alphabetic ASCII character)

Follow these substeps:

1. If *got number* is true, let *finished* be true.
2. If *finished* is true, skip to the next step in the overall set of steps.
3. Let *negated* be false.

↪ Any other character

Follow these substeps:

1. If *finished* is true, skip to the next step in the overall set of steps.
2. Let *negated* be false.
3. Let *bogus* be true.
4. If *started* is true, then return the *numbers* list, and abort. (The value in *value* is not appended to the list first; it is dropped.)
14. Advance *position* to the next character in *input*, or to beyond the end of the string if there are no more characters.
15. If *position* points to a character (and not to beyond the end of *input*), jump to the big *Parser* step above.
16. If *negated* is true, then negate *value*.
17. If *got number* is true, then append *value* to the *numbers* list.
18. Return the *numbers* list and abort.

2.4.4.6 Lists of dimensions

The **rules for parsing a list of dimensions** are as follows. These rules return a list of zero or more pairs consisting of a number and a unit, the unit being one of *percentage*, *relative*, and *absolute*.

1. Let *raw input* be the string being parsed.

2. If the last character in *raw input* is a U+002C COMMA character (,), then remove that character from *raw input*.
3. [Split the string *raw input* on commas^{p81}](#). Let *raw tokens* be the resulting list of tokens.
4. Let *result* be an empty list of number/unit pairs.
5. For each token in *raw tokens*, run the following substeps:
 1. Let *input* be the token.
 2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
 3. Let *value* be the number 0.
 4. Let *unit* be *absolute*.
 5. If *position* is past the end of *input*, set *unit* to *relative* and jump to the last substep.
 6. If the character at *position* is an [ASCII digit^{p58}](#), [collect a sequence of characters^{p59}](#) that are [ASCII digits^{p58}](#), interpret the resulting sequence as an integer in base ten, and increment *value* by that integer.
 7. If the character at *position* is a U+002E FULL STOP character (.), run these substeps:
 1. [Collect a sequence of characters^{p59}](#) consisting of [space characters^{p58}](#) and [ASCII digits^{p58}](#). Let *s* be the resulting sequence.
 2. Remove all [space characters^{p58}](#) in *s*.
 3. If *s* is not the empty string, run these subsubsteps:
 1. Let *length* be the number of characters in *s* (after the spaces were removed).
 2. Let *fraction* be the result of interpreting *s* as a base-ten integer, and then dividing that number by 10^{length} .
 3. Increment *value* by *fraction*.
 8. [Skip whitespace^{p59}](#).
 9. If the character at *position* is a U+0025 PERCENT SIGN character (%), then set *unit* to *percentage*. Otherwise, if the character at *position* is a U+002A ASTERISK character (*), then set *unit* to *relative*.
 10. Add an entry to *result* consisting of the number given by *value* and the unit given by *unit*.
6. Return the list *result*.

2.4.5 Dates and times

In the algorithms below, the **number of days in month** *month* of year *year* is: 31 if *month* is 1, 3, 5, 7, 8, 10, or 12; 30 if *month* is 4, 6, 9, or 11; 29 if *month* is 2 and *year* is a number divisible by 400, or if *year* is a number divisible by 4 but not by 100; and 28 otherwise. This takes into account leap years in the Gregorian calendar. [\[GREGORIAN\]^{p1150}](#)

When [ASCII digits^{p58}](#) are used in the date and time syntaxes defined in this section, they express numbers in base ten.

Note While the formats described here are intended to be subsets of the corresponding ISO8601 formats, this specification defines parsing rules in much more detail than ISO8601. Implementors are therefore encouraged to carefully examine any date parsing libraries before using them to implement the parsing rules described below; ISO8601 libraries might not parse dates and times in exactly the same manner. [\[ISO8601\]^{p1150}](#)

Where this specification refers to the **proleptic Gregorian calendar**, it means the modern Gregorian calendar, extrapolated backwards to year 1. A date in the [proleptic Gregorian calendar^{p66}](#), sometimes explicitly referred to as a **proleptic-Gregorian date**, is one that is described using that calendar even if that calendar was not in use at the time (or place) in question. [\[GREGORIAN\]^{p1150}](#)

Note The use of the Gregorian calendar as the wire format in this specification is an arbitrary choice resulting from the cultural biases of those involved in the decision. See also the section discussing [date, time, and number formats^{p446}](#) in forms (for authors), [implementation notes regarding localization of form controls^{p482}](#), and the [time^{p227}](#) element.

2.4.5.1 Months

A **month** consists of a specific [proleptic-Gregorian date^{p66}](#) with no time-zone information and no date information beyond a year and a month. [\[GREGORIAN\]^{p1150}](#)

A string is a **valid month string** representing a year *year* and month *month* if it consists of the following components in the given order:

1. Four or more [ASCII digits^{p58}](#), representing *year*, where *year* > 0
2. A U+002D HYPHEN-MINUS character (-)
3. Two [ASCII digits^{p58}](#), representing the month *month*, in the range $1 \leq \text{month} \leq 12$

The rules to **parse a month string** are as follows. This will return either a year and month, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. [Parse a month component^{p67}](#) to obtain *year* and *month*. If this returns nothing, then fail.
4. If *position* is *not* beyond the end of *input*, then fail.
5. Return *year* and *month*.

The rules to **parse a month component**, given an *input* string and a *position*, are as follows. This will return either a year and a month, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. [Collect a sequence of characters^{p59}](#) that are [ASCII digits^{p58}](#). If the collected sequence is not at least four characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the *year*.
2. If *year* is not a number greater than zero, then fail.
3. If *position* is beyond the end of *input* or if the character at *position* is not a U+002D HYPHEN-MINUS character, then fail. Otherwise, move *position* forwards one character.
4. [Collect a sequence of characters^{p59}](#) that are [ASCII digits^{p58}](#). If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the *month*.
5. If *month* is not a number in the range $1 \leq \text{month} \leq 12$, then fail.
6. Return *year* and *month*.

2.4.5.2 Dates

A **date** consists of a specific [proleptic-Gregorian date^{p66}](#) with no time-zone information, consisting of a year, a month, and a day. [\[GREGORIAN\]^{p1150}](#)

A string is a **valid date string** representing a year *year*, month *month*, and day *day* if it consists of the following components in the given order:

1. A [valid month string^{p67}](#), representing *year* and *month*
2. A U+002D HYPHEN-MINUS character (-)
3. Two [ASCII digits^{p58}](#), representing *day*, in the range $1 \leq \text{day} \leq \text{maxday}$ where *maxday* is the [number of days in the month *month* and year *year*^{p66}](#)

The rules to **parse a date string** are as follows. This will return either a date, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. [Parse a date component^{p68}](#) to obtain *year*, *month*, and *day*. If this returns nothing, then fail.
4. If *position* is *not* beyond the end of *input*, then fail.
5. Let *date* be the date with year *year*, month *month*, and day *day*.
6. Return *date*.

The rules to **parse a date component**, given an *input* string and a *position*, are as follows. This will return either a year, a month, and a day, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. [Parse a month component^{p67}](#) to obtain *year* and *month*. If this returns nothing, then fail.
2. Let *maxday* be the [number of days in month *month* of year *year*^{p66}](#).
3. If *position* is beyond the end of *input* or if the character at *position* is not a U+002D HYPHEN-MINUS character, then fail. Otherwise, move *position* forwards one character.
4. [Collect a sequence of characters^{p59}](#) that are [ASCII digits^{p58}](#). If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the *day*.
5. If *day* is not a number in the range $1 \leq \text{day} \leq \text{maxday}$, then fail.
6. Return *year*, *month*, and *day*.

2.4.5.3 Yearless dates

A **yearless date** consists of a Gregorian month and a day within that month, but with no associated year. [\[GREGORIAN\]^{p1150}](#)

A string is a **valid yearless date string** representing a month *month* and a day *day* if it consists of the following components in the given order:

1. Optionally, two U+002D HYPHEN-MINUS characters (-)
2. Two [ASCII digits^{p58}](#), representing the month *month*, in the range $1 \leq \text{month} \leq 12$
3. A U+002D HYPHEN-MINUS character (-)
4. Two [ASCII digits^{p58}](#), representing *day*, in the range $1 \leq \text{day} \leq \text{maxday}$ where *maxday* is the [number of days^{p66}](#) in the month *month* and any arbitrary leap year (e.g. 4 or 2000)

Note In other words, if the month is "02", meaning February, then the day can be 29, as if the year was a leap year.

The rules to **parse a yearless date string** are as follows. This will return either a month and a day, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. [Parse a yearless date component^{p68}](#) to obtain *month* and *day*. If this returns nothing, then fail.
4. If *position* is *not* beyond the end of *input*, then fail.
5. Return *month* and *day*.

The rules to **parse a yearless date component**, given an *input* string and a *position*, are as follows. This will return either a month and a day, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. [Collect a sequence of characters](#)^{p59} that are U+002D HYPHEN-MINUS characters (-). If the collected sequence is not exactly zero or two characters long, then fail.
2. [Collect a sequence of characters](#)^{p59} that are [ASCII digits](#)^{p58}. If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the *month*.
3. If *month* is not a number in the range $1 \leq month \leq 12$, then fail.
4. Let *maxday* be the [number of days](#)^{p66} in month *month* of any arbitrary leap year (e.g. 4 or 2000).
5. If *position* is beyond the end of *input* or if the character at *position* is not a U+002D HYPHEN-MINUS character, then fail. Otherwise, move *position* forwards one character.
6. [Collect a sequence of characters](#)^{p59} that are [ASCII digits](#)^{p58}. If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the *day*.
7. If *day* is not a number in the range $1 \leq day \leq maxday$, then fail.
8. Return *month* and *day*.

2.4.5.4 Times

A **time** consists of a specific time with no time-zone information, consisting of an hour, a minute, a second, and a fraction of a second.

A string is a **valid time string** representing an hour *hour*, a minute *minute*, and a second *second* if it consists of the following components in the given order:

1. Two [ASCII digits](#)^{p58}, representing *hour*, in the range $0 \leq hour \leq 23$
2. A U+003A COLON character (:)
3. Two [ASCII digits](#)^{p58}, representing *minute*, in the range $0 \leq minute \leq 59$
4. If *second* is non-zero, or optionally if *second* is zero:
 1. A U+003A COLON character (:)
 2. Two [ASCII digits](#)^{p58}, representing the integer part of *second*, in the range $0 \leq s \leq 59$
 3. If *second* is not an integer, or optionally if *second* is an integer:
 1. A 002E FULL STOP character (.)
 2. One, two, or three [ASCII digits](#)^{p58}, representing the fractional part of *second*

Note The second component cannot be 60 or 61; leap seconds cannot be represented.

The rules to **parse a time string** are as follows. This will return either a time, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. [Parse a time component](#)^{p69} to obtain *hour*, *minute*, and *second*. If this returns nothing, then fail.
4. If *position* is not beyond the end of *input*, then fail.
5. Let *time* be the time with hour *hour*, minute *minute*, and second *second*.
6. Return *time*.

The rules to **parse a time component**, given an *input* string and a *position*, are as follows. This will return either an hour, a minute, and a second, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. [Collect a sequence of characters](#)^{p59} that are [ASCII digits](#)^{p58}. If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the *hour*.
2. If *hour* is not a number in the range $0 \leq hour \leq 23$, then fail.

3. If *position* is beyond the end of *input* or if the character at *position* is not a U+003A COLON character, then fail. Otherwise, move *position* forwards one character.
4. [Collect a sequence of characters^{p59}](#) that are [ASCII digits^{p58}](#). If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the *minute*.
5. If *minute* is not a number in the range $0 \leq minute \leq 59$, then fail.
6. Let *second* be a string with the value "0".
7. If *position* is not beyond the end of *input* and the character at *position* is a U+003A COLON, then run these substeps:
 1. Advance *position* to the next character in *input*.
 2. If *position* is beyond the end of *input*, or at the last character in *input*, or if the next *two* characters in *input* starting at *position* are not both [ASCII digits^{p58}](#), then fail.
 3. [Collect a sequence of characters^{p59}](#) that are either [ASCII digits^{p58}](#) or U+002E FULL STOP characters. If the collected sequence is three characters long, or if it is longer than three characters long and the third character is not a U+002E FULL STOP character, or if it has more than one U+002E FULL STOP character, then fail. Otherwise, let the collected string be *second* instead of its previous value.
 8. Interpret *second* as a base-ten number (possibly with a fractional part). Let *second* be that number instead of the string version.
 9. If *second* is not a number in the range $0 \leq second < 60$, then fail.
 10. Return *hour*, *minute*, and *second*.

2.4.5.5 Local dates and times

A **local date and time** consists of a specific [proleptic-Gregorian date^{p66}](#), consisting of a year, a month, and a day, and a time, consisting of an hour, a minute, a second, and a fraction of a second, but expressed without a time zone. [\[GREGORIAN\]^{p1150}](#)

A string is a **valid local date and time string** representing a date and time if it consists of the following components in the given order:

1. A [valid date string^{p67}](#) representing the date
2. A U+0054 LATIN CAPITAL LETTER T character (T) or a U+0020 SPACE character
3. A [valid time string^{p69}](#) representing the time

A string is a **valid normalised local date and time string** representing a date and time if it consists of the following components in the given order:

1. A [valid date string^{p67}](#) representing the date
2. A U+0054 LATIN CAPITAL LETTER T character (T)
3. A [valid time string^{p69}](#) representing the time, expressed as the shortest possible string for the given time (e.g. omitting the seconds component entirely if the given time is zero seconds past the minute)

The rules to **parse a local date and time string** are as follows. This will return either a date and time, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. [Parse a date component^{p68}](#) to obtain *year*, *month*, and *day*. If this returns nothing, then fail.
4. If *position* is beyond the end of *input* or if the character at *position* is neither a U+0054 LATIN CAPITAL LETTER T character (T) nor a U+0020 SPACE character, then fail. Otherwise, move *position* forwards one character.
5. [Parse a time component^{p69}](#) to obtain *hour*, *minute*, and *second*. If this returns nothing, then fail.
6. If *position* is not beyond the end of *input*, then fail.

7. Let *date* be the date with year *year*, month *month*, and day *day*.
8. Let *time* be the time with hour *hour*, minute *minute*, and second *second*.
9. Return *date* and *time*.

2.4.5.6 Time zones

A **time-zone offset** consists of a signed number of hours and minutes.

A string is a **valid time-zone offset string** representing a time-zone offset if it consists of either:

- A U+005A LATIN CAPITAL LETTER Z character (Z), allowed only if the time zone is UTC
- Or, the following components, in the given order:
 1. Either a U+002B PLUS SIGN character (+) or, if the time-zone offset is not zero, a U+002D HYPHEN-MINUS character (-), representing the sign of the time-zone offset
 2. Two [ASCII digits](#)⁵⁵⁸, representing the hours component *hour* of the time-zone offset, in the range $0 \leq \text{hour} \leq 23$
 3. Optionally, a U+003A COLON character (:)
 4. Two [ASCII digits](#)⁵⁵⁸, representing the minutes component *minute* of the time-zone offset, in the range $0 \leq \text{minute} \leq 59$

Note This format allows for time-zone offsets from -23:59 to +23:59. Right now, in practice, the range of offsets of actual time zones is -12:00 to +14:00, and the minutes component of offsets of actual time zones is always either 00, 30, or 45. There is no guarantee that this will remain so forever, however, since time zones are used as political footballs and are thus subject to very whimsical policy decisions.

Note See also the usage notes and examples in the [global date and time](#)⁵⁷² section below for details on using time-zone offsets with historical times that predate the formation of formal time zones.

The rules to **parse a time-zone offset string** are as follows. This will return either a time-zone offset, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. [Parse a time-zone offset component](#)⁵⁷¹ to obtain *timezonehours* and *timzoneminutes*. If this returns nothing, then fail.
4. If *position* is not beyond the end of *input*, then fail.
5. Return the time-zone offset that is *timezonehours* hours and *timzoneminutes* minutes from UTC.

The rules to **parse a time-zone offset component**, given an *input* string and a *position*, are as follows. This will return either time-zone hours and time-zone minutes, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. If the character at *position* is a U+005A LATIN CAPITAL LETTER Z character (Z), then:
 1. Let *timezonehours* be 0.
 2. Let *timzoneminutes* be 0.
 3. Advance *position* to the next character in *input*.

Otherwise, if the character at *position* is either a U+002B PLUS SIGN (+) or a U+002D HYPHEN-MINUS (-), then:

1. If the character at *position* is a U+002B PLUS SIGN (+), let *sign* be "positive". Otherwise, it's a U+002D HYPHEN-MINUS (-); let *sign* be "negative".
2. Advance *position* to the next character in *input*.
3. [Collect a sequence of characters](#)⁵⁵⁹ that are [ASCII digits](#)⁵⁵⁸. Let *s* be the collected sequence.
4. If *s* is exactly two characters long, then run these substeps:

1. Interpret *s* as a base-ten integer. Let that number be the *timezonehours*.
2. If *position* is beyond the end of *input* or if the character at *position* is not a U+003A COLON character, then fail. Otherwise, move *position* forwards one character.
3. Collect a sequence of characters^{p59} that are ASCII digits^{p58}. If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the *timzoneminutes*.

If *s* is exactly four characters long, then run these substeps:

1. Interpret the first two characters of *s* as a base-ten integer. Let that number be the *timezonehours*.
2. Interpret the last two characters of *s* as a base-ten integer. Let that number be the *timzoneminutes*.

Otherwise, fail.

5. If *timezonehours* is not a number in the range $0 \leq \text{timezonehours} \leq 23$, then fail.
6. If *sign* is "negative", then negate *timezonehours*.
7. If *timzoneminutes* is not a number in the range $0 \leq \text{timzoneminutes} \leq 59$, then fail.
8. If *sign* is "negative", then negate *timzoneminutes*.

Otherwise, fail.

2. Return *timezonehours* and *timzoneminutes*.

2.4.5.7 Global dates and times

A **global date and time** consists of a specific [proleptic-Gregorian date^{p66}](#), consisting of a year, a month, and a day, and a time, consisting of an hour, a minute, a second, and a fraction of a second, expressed with a time-zone offset, consisting of a signed number of hours and minutes. [\[GREGORIAN\]^{p1150}](#)

A string is a **valid global date and time string** representing a date, time, and a time-zone offset if it consists of the following components in the given order:

1. A [valid date string^{p67}](#) representing the date
2. A U+0054 LATIN CAPITAL LETTER T character (T) or a U+0020 SPACE character
3. A [valid time string^{p69}](#) representing the time
4. A [valid time-zone offset string^{p71}](#) representing the time-zone offset

Times in dates before the formation of UTC in the mid twentieth century must be expressed and interpreted in terms of UT1 (contemporary Earth solar time at the 0° longitude), not UTC (the approximation of UT1 that ticks in SI seconds). Time before the formation of time zones must be expressed and interpreted as UT1 times with explicit time zones that approximate the contemporary difference between the appropriate local time and the time observed at the location of Greenwich, London.

Example

The following are some examples of dates written as [valid global date and time strings^{p72}](#).

"0037-12-13 00:00Z"

Midnight in areas using London time on the birthday of Nero (the Roman Emperor). See below for further discussion on which date this actually corresponds to.

"1979-10-14T12:00:00.001-04:00"

One millisecond after noon on October 14th 1979, in the time zone in use on the east coast of the USA during daylight saving time.

"8592-01-01T02:09+02:09"

Midnight UTC on the 1st of January, 8592. The time zone associated with that time is two hours and nine minutes ahead of UTC, which is not currently a real time zone, but is nonetheless allowed.

Several things are notable about these dates:

- Years with fewer than four digits have to be zero-padded. The date "37-12-13" would not be a valid date.
- If the "T" is replaced by a space, it must be a single space character. The string "2001-12-21 12:00Z" (with two spaces between the components) would not be parsed successfully.
- To unambiguously identify a moment in time prior to the introduction of the Gregorian calendar (insofar as moments in time before the formation of UTC can be unambiguously identified), the date has to be first converted to the Gregorian calendar from the calendar in use at the time (e.g. from the Julian calendar). The date of Nero's birth is the 15th of December 37, in the Julian Calendar, which is the 13th of December 37 in the [proleptic Gregorian calendar](#)^{p66}.
- The time and time-zone offset components are not optional.
- Dates before the year one can't be represented as a datetime in this version of HTML.
- Times of specific events in ancient times are, at best, approximations, since time was not well coordinated or measured until relatively recent decades.
- Time-zone offsets differ based on daylight savings time.

A string is a **valid normalised forced-UTC global date and time string** representing a date, time, and a time-zone offset if it consists of the following components in the given order:

1. A [valid date string](#)^{p67} representing the date converted to the UTC time zone
2. A U+0054 LATIN CAPITAL LETTER T character (T)
3. A [valid time string](#)^{p69} representing the time converted to the UTC time zone and expressed as the shortest possible string for the given time (e.g. omitting the seconds component entirely if the given time is zero seconds past the minute)
4. A U+005A LATIN CAPITAL LETTER Z character (Z)

The rules to **parse a global date and time string** are as follows. This will return either a time in UTC, with associated time-zone offset information for round-tripping or display purposes, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. [Parse a date component](#)^{p68} to obtain *year*, *month*, and *day*. If this returns nothing, then fail.
4. If *position* is beyond the end of *input* or if the character at *position* is neither a U+0054 LATIN CAPITAL LETTER T character (T) nor a U+0020 SPACE character, then fail. Otherwise, move *position* forwards one character.
5. [Parse a time component](#)^{p69} to obtain *hour*, *minute*, and *second*. If this returns nothing, then fail.
6. If *position* is beyond the end of *input*, then fail.
7. [Parse a time-zone offset component](#)^{p71} to obtain *timezonehours* and *timezoneminutes*. If this returns nothing, then fail.
8. If *position* is *not* beyond the end of *input*, then fail.
9. Let *time* be the moment in time at year *year*, month *month*, day *day*, hours *hour*, minute *minute*, second *second*, subtracting *timezonehours* hours and *timezoneminutes* minutes. That moment in time is a moment in the UTC time zone.
10. Let *timezone* be *timezonehours* hours and *timezoneminutes* minutes from UTC.
11. Return *time* and *timezone*.

2.4.5.8 Weeks

A **week** consists of a week-year number and a week number representing a seven-day period starting on a Monday. Each week-year in this calendaring system has either 52 or 53 such seven-day periods, as defined below. The seven-day period starting on the Gregorian date Monday

December 29th 1969 (1969-12-29) is defined as week number 1 in week-year 1970. Consecutive weeks are numbered sequentially. The week before the number 1 week in a week-year is the last week in the previous week-year, and vice versa. [\[GREGORIAN\]^{p1150}](#)

A week-year with a number year has 53 weeks if it corresponds to either a year year in the [proleptic Gregorian calendar^{p66}](#) that has a Thursday as its first day (January 1st), or a year year in the [proleptic Gregorian calendar^{p66}](#) that has a Wednesday as its first day (January 1st) and where year is a number divisible by 400, or a number divisible by 4 but not by 100. All other week-years have 52 weeks.

The **week number of the last day** of a week-year with 53 weeks is 53; the week number of the last day of a week-year with 52 weeks is 52.

Note *The week-year number of a particular day can be different than the number of the year that contains that day in the proleptic Gregorian calendar^{p66}. The first week in a week-year y is the week that contains the first Thursday of the Gregorian year y.*

Note *For modern purposes, a week^{p73} as defined here is equivalent to ISO weeks as defined in ISO 8601. [\[ISO8601\]^{p1150}](#)*

A string is a **valid week string** representing a week-year year and week week if it consists of the following components in the given order:

1. Four or more [ASCII digits^{p58}](#), representing year, where year > 0
2. A U+002D HYPHEN-MINUS character (-)
3. A U+0057 LATIN CAPITAL LETTER W character (W)
4. Two [ASCII digits^{p58}](#), representing the week week, in the range 1 ≤ week ≤ maxweek, where maxweek is the [week number of the last day^{p74}](#) of week-year year

The rules to **parse a week string** are as follows. This will return either a week-year number and week number, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. **Collect a sequence of characters^{p59}** that are [ASCII digits^{p58}](#). If the collected sequence is not at least four characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the *year*.
4. If *year* is not a number greater than zero, then fail.
5. If *position* is beyond the end of *input* or if the character at *position* is not a U+002D HYPHEN-MINUS character, then fail. Otherwise, move *position* forwards one character.
6. If *position* is beyond the end of *input* or if the character at *position* is not a U+0057 LATIN CAPITAL LETTER W character (W), then fail. Otherwise, move *position* forwards one character.
7. **Collect a sequence of characters^{p59}** that are [ASCII digits^{p58}](#). If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the *week*.
8. Let *maxweek* be the [week number of the last day^{p74}](#) of year *year*.
9. If *week* is not a number in the range 1 ≤ week ≤ *maxweek*, then fail.
10. If *position* is *not* beyond the end of *input*, then fail.
11. Return the week-year number *year* and the week number *week*.

2.4.5.9 Durations

A **duration** consists of a number of seconds.

Note *Since months and seconds are not comparable (a month is not a precise number of seconds, but is instead a period whose exact length depends on the precise day from which it is measured) a duration^{p74} as defined in this specification cannot include months (or years, which are equivalent to twelve months). Only durations that describe a specific number of seconds can be described.*

A string is a **valid duration string** representing a [duration^{p74}](#) t if it consists of either of the following:

- A literal U+0050 LATIN CAPITAL LETTER P character followed by one or more of the following subcomponents, in the order given, where the number of days, hours, minutes, and seconds corresponds to the same number of seconds as in *t*:
 1. One or more [ASCII digits^{p58}](#) followed by a U+0044 LATIN CAPITAL LETTER D character, representing a number of days.
 2. A U+0054 LATIN CAPITAL LETTER T character followed by one or more of the following subcomponents, in the order given:
 1. One or more [ASCII digits^{p58}](#) followed by a U+0048 LATIN CAPITAL LETTER H character, representing a number of hours.
 2. One or more [ASCII digits^{p58}](#) followed by a U+004D LATIN CAPITAL LETTER M character, representing a number of minutes.
 3. The following components:
 1. One or more [ASCII digits^{p58}](#), representing a number of seconds.
 2. Optionally, a U+002E FULL STOP character (.) followed by one, two, or three [ASCII digits^{p58}](#), representing a fraction of a second.
 3. A U+0053 LATIN CAPITAL LETTER S character.

Note *This, as with a number of other date- and time-related microsyntaxes defined in this specification, is based on one of the formats defined in ISO 8601. [\[ISO8601\]¹¹⁵⁰](#)*

- One or more [duration time components^{p75}](#), each with a different [duration time component scale^{p75}](#), in any order; the sum of the represented seconds being equal to the number of seconds in *t*.

A **duration time component** is a string consisting of the following components:

1. Zero or more [space characters^{p58}](#).
2. One or more [ASCII digits^{p58}](#), representing a number of time units, scaled by the [duration time component scale^{p75}](#) specified (see below) to represent a number of seconds.
3. If the [duration time component scale^{p75}](#) specified is 1 (i.e. the units are seconds), then, optionally, a U+002E FULL STOP character (.) followed by one, two, or three [ASCII digits^{p58}](#), representing a fraction of a second.
4. Zero or more [space characters^{p58}](#).
5. One of the following characters, representing the **duration time component scale** of the time unit used in the numeric part of the [duration time component^{p75}](#):

U+0057 LATIN CAPITAL LETTER W character

U+0077 LATIN SMALL LETTER W character

Weeks. The scale is 604800.

U+0044 LATIN CAPITAL LETTER D character

U+0064 LATIN SMALL LETTER D character

Days. The scale is 86400.

U+0048 LATIN CAPITAL LETTER H character

U+0068 LATIN SMALL LETTER H character

Hours. The scale is 3600.

U+004D LATIN CAPITAL LETTER M character

U+006D LATIN SMALL LETTER M character

Minutes. The scale is 60.

U+0053 LATIN CAPITAL LETTER S character

U+0073 LATIN SMALL LETTER S character

Seconds. The scale is 1.

6. Zero or more [space characters^{p58}](#).

Note *This is not based on any of the formats in ISO 8601. It is intended to be a more human-readable alternative to the ISO 8601 duration format.*

The rules to **parse a duration string** are as follows. This will return either a [duration^{b74}](#) or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Let *months*, *seconds*, and *component count* all be zero.
4. Let *M-disambiguator* be *minutes*.

Note *This flag's other value is months. It is used to disambiguate the "M" unit in ISO8601 durations, which use the same unit for months and minutes. Months are not allowed, but are parsed for future compatibility and to avoid misinterpreting ISO8601 durations that would be valid in other contexts.*

5. [Skip whitespace^{b59}](#).
6. If *position* is past the end of *input*, then fail.
7. If the character in *input* pointed to by *position* is a U+0050 LATIN CAPITAL LETTER P character, then advance *position* to the next character, set *M-disambiguator* to *months*, and [skip whitespace^{b59}](#).
8. Run the following substeps in a loop, until a step requiring the loop to be broken or the entire algorithm to fail is reached:
 1. Let *units* be undefined. It will be assigned one of the following values: *years*, *months*, *weeks*, *days*, *hours*, *minutes*, and *seconds*.
 2. Let *next character* be undefined. It is used to process characters from the *input*.
 3. If *position* is past the end of *input*, then break the loop.
 4. If the character in *input* pointed to by *position* is a U+0054 LATIN CAPITAL LETTER T character, then advance *position* to the next character, set *M-disambiguator* to *minutes*, [skip whitespace^{b59}](#), and return to the top of the loop.
 5. Set *next character* to the character in *input* pointed to by *position*.
 6. If *next character* is a U+002E FULL STOP character (.), then let *N* equal zero. (Do not advance *position*. That is taken care of below.)

Otherwise, if *next character* is an [ASCII digit^{b58}](#), then [collect a sequence of characters^{b59}](#) that are [ASCII digits^{b58}](#), interpret the resulting sequence as a base-ten integer, and let *N* be that number.

Otherwise *next character* is not part of a number; fail.

7. If *position* is past the end of *input*, then fail.
8. Set *next character* to the character in *input* pointed to by *position*, and this time advance *position* to the next character. (If *next character* was a U+002E FULL STOP character (.) before, it will still be that character this time.)
9. If *next character* is a U+002E FULL STOP character (.), then run these substeps:
 1. [Collect a sequence of characters^{b59}](#) that are [ASCII digits^{b58}](#). Let *s* be the resulting sequence.
 2. If *s* is the empty string, then fail.
 3. Let *length* be the number of characters in *s*.
 4. Let *fraction* be the result of interpreting *s* as a base-ten integer, and then dividing that number by 10^{length} .
 5. Increment *N* by *fraction*.
 6. [Skip whitespace^{b59}](#).
7. If *position* is past the end of *input*, then fail.
8. Set *next character* to the character in *input* pointed to by *position*, and advance *position* to the next character.
9. If *next character* is neither a U+0053 LATIN CAPITAL LETTER S character nor a U+0073 LATIN SMALL LETTER S character, then fail.

10. Set *units* to *seconds*.

Otherwise, run these substeps:

1. If *next character* is a [space character^{p58}](#), then [skip whitespace^{p59}](#), set *next character* to the character in *input* pointed to by *position*, and advance *position* to the next character.

2. If *next character* is a U+0059 LATIN CAPITAL LETTER Y character, or a U+0079 LATIN SMALL LETTER Y character, set *units* to *years* and set *M-disambiguator* to *months*.

If *next character* is a U+004D LATIN CAPITAL LETTER M character or a U+006D LATIN SMALL LETTER M character, and *M-disambiguator* is *months*, then set *units* to *months*.

If *next character* is a U+0057 LATIN CAPITAL LETTER W character or a U+0077 LATIN SMALL LETTER W character, set *units* to *weeks* and set *M-disambiguator* to *minutes*.

If *next character* is a U+0044 LATIN CAPITAL LETTER D character or a U+0064 LATIN SMALL LETTER D character, set *units* to *days* and set *M-disambiguator* to *minutes*.

If *next character* is a U+0048 LATIN CAPITAL LETTER H character or a U+0068 LATIN SMALL LETTER H character, set *units* to *hours* and set *M-disambiguator* to *minutes*.

If *next character* is a U+004D LATIN CAPITAL LETTER M character or a U+006D LATIN SMALL LETTER M character, and *M-disambiguator* is *minutes*, then set *units* to *minutes*.

If *next character* is a U+0053 LATIN CAPITAL LETTER S character or a U+0073 LATIN SMALL LETTER S character, set *units* to *seconds* and set *M-disambiguator* to *minutes*.

Otherwise if *next character* is none of the above characters, then fail.

10. Increment *component count*.

11. Let *multiplier* be 1.

12. If *units* is *years*, multiply *multiplier* by 12 and set *units* to *months*.

13. If *units* is *months*, add the product of *N* and *multiplier* to *months*.

Otherwise, run these substeps:

1. If *units* is *weeks*, multiply *multiplier* by 7 and set *units* to *days*.

2. If *units* is *days*, multiply *multiplier* by 24 and set *units* to *hours*.

3. If *units* is *hours*, multiply *multiplier* by 60 and set *units* to *minutes*.

4. If *units* is *minutes*, multiply *multiplier* by 60 and set *units* to *seconds*.

5. Forcibly, *units* is now *seconds*. Add the product of *N* and *multiplier* to *seconds*.

14. [Skip whitespace^{p59}](#).

9. If *component count* is zero, fail.

10. If *months* is not zero, fail.

11. Return the [duration^{b74}](#) consisting of *seconds* seconds.

2.4.5.10 Vaguer moments in time

A string is a **valid date string with optional time** if it is also one of the following:

- A [valid date string^{p67}](#)
- A [valid global date and time string^{p72}](#)

The rules to **parse a date or time string** are as follows. The algorithm will return either a [date^{p67}](#), a [time^{p69}](#), a [global date and time^{p72}](#), or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Set *start position* to the same position as *position*.
4. Set the *date present* and *time present* flags to true.
5. [Parse a date component^{p68}](#) to obtain *year*, *month*, and *day*. If this fails, then set the *date present* flag to false.
6. If *date present* is true, and *position* is not beyond the end of *input*, and the character at *position* is either a U+0054 LATIN CAPITAL LETTER T character (T) or a U+0020 SPACE character, then advance *position* to the next character in *input*.
Otherwise, if *date present* is true, and either *position* is beyond the end of *input* or the character at *position* is neither a U+0054 LATIN CAPITAL LETTER T character (T) nor a U+0020 SPACE character, then set *time present* to false.
Otherwise, if *date present* is false, set *position* back to the same position as *start position*.
7. If the *time present* flag is true, then [parse a time component^{p69}](#) to obtain *hour*, *minute*, and *second*. If this returns nothing, then fail.
8. If the *date present* and *time present* flags are both true, but *position* is beyond the end of *input*, then fail.
9. If the *date present* and *time present* flags are both true, [parse a time-zone offset component^{p71}](#) to obtain *timezonehours* and *timezoneminutes*. If this returns nothing, then fail.
10. If *position* is not beyond the end of *input*, then fail.
11. If the *date present* flag is true and the *time present* flag is false, then let *date* be the date with year *year*, month *month*, and day *day*, and return *date*.
Otherwise, if the *time present* flag is true and the *date present* flag is false, then let *time* be the time with hour *hour*, minute *minute*, and second *second*, and return *time*.
Otherwise, let *time* be the moment in time at year *year*, month *month*, day *day*, hours *hour*, minute *minute*, second *second*, subtracting *timezonehours* hours and *timezoneminutes* minutes, that moment in time being a moment in the UTC time zone; let *timezone* be *timezonehours* hours and *timezoneminutes* minutes from UTC; and return *time* and *timezone*.

2.4.6 Colours

A **simple colour** consists of three 8-bit numbers in the range 0..255, representing the red, green, and blue components of the colour respectively, in the sRGB colour space. [\[SRGB\]^{p1153}](#)

A string is a **valid simple colour** if it is exactly seven characters long, and the first character is a U+0023 NUMBER SIGN character (#), and the remaining six characters are all [ASCII hex digits^{p59}](#), with the first two digits representing the red component, the middle two digits representing the green component, and the last two digits representing the blue component, in hexadecimal.

A string is a **valid lowercase simple colour** if it is a [valid simple colour^{p78}](#) and doesn't use any characters in the range U+0041 LATIN CAPITAL LETTER A to U+0046 LATIN CAPITAL LETTER F.

The **rules for parsing simple colour values** are as given in the following algorithm. When invoked, the steps must be followed in the order given, aborting at the first step that returns a value. This algorithm will return either a [simple colour^{p78}](#) or an error.

1. Let *input* be the string being parsed.
2. If *input* is not exactly seven characters long, then return an error.
3. If the first character in *input* is not a U+0023 NUMBER SIGN character (#), then return an error.
4. If the last six characters of *input* are not all [ASCII hex digits^{p59}](#), then return an error.
5. Let *result* be a [simple colour^{p78}](#).

6. Interpret the second and third characters as a hexadecimal number and let the result be the red component of *result*.
7. Interpret the fourth and fifth characters as a hexadecimal number and let the result be the green component of *result*.
8. Interpret the sixth and seventh characters as a hexadecimal number and let the result be the blue component of *result*.
9. Return *result*.

The **rules for serialising simple colour values** given a [simple colour^{p78}](#) are as given in the following algorithm:

1. Let *result* be a string consisting of a single U+0023 NUMBER SIGN character (#).
2. Convert the red, green, and blue components in turn to two-digit hexadecimal numbers using [lowercase ASCII hex digits^{p59}](#), zero-padding if necessary, and append these numbers to *result*, in the order red, green, blue.
3. Return *result*, which will be a [valid lowercase simple colour^{p78}](#).

Some obsolete legacy attributes parse colours in a more complicated manner, using the **rules for parsing a legacy colour value**, which are given in the following algorithm. When invoked, the steps must be followed in the order given, aborting at the first step that returns a value. This algorithm will return either a [simple colour^{p78}](#) or an error.

1. Let *input* be the string being parsed.
2. If *input* is the empty string, then return an error.
3. [Strip leading and trailing whitespace^{p59}](#) from *input*.
4. If *input* is an [ASCII case-insensitive^{p58}](#) match for the string "transparent", then return an error.
5. If *input* is an [ASCII case-insensitive^{p58}](#) match for one of the named colours, then return the [simple colour^{p78}](#) corresponding to that keyword. [\[CSSCOLOR\]^{p1149}](#)

Note [CSS2 System Colors are not recognised.](#)
6. If *input* is four characters long, and the first character in *input* is a U+0023 NUMBER SIGN character (#), and the last three characters of *input* are all [ASCII hex digits^{p59}](#), then run these substeps:
 1. Let *result* be a [simple colour^{p78}](#).
 2. Interpret the second character of *input* as a hexadecimal digit; let the red component of *result* be the resulting number multiplied by 17.
 3. Interpret the third character of *input* as a hexadecimal digit; let the green component of *result* be the resulting number multiplied by 17.
 4. Interpret the fourth character of *input* as a hexadecimal digit; let the blue component of *result* be the resulting number multiplied by 17.
 5. Return *result*.
7. Replace any characters in *input* that have a Unicode code point greater than U+FFFF (i.e. any characters that are not in the basic multilingual plane) with the two-character string "00".
8. If *input* is longer than 128 characters, truncate *input*, leaving only the first 128 characters.
9. If the first character in *input* is a U+0023 NUMBER SIGN character (#), remove it.
10. Replace any character in *input* that is not an [ASCII hex digit^{p59}](#) with the character U+0030 DIGIT ZERO (0).
11. While *input*'s length is zero or not a multiple of three, append a U+0030 DIGIT ZERO (0) character to *input*.
12. Split *input* into three strings of equal length, to obtain three components. Let *length* be the length of those components (one third the length of *input*).
13. If *length* is greater than 8, then remove the leading *length*-8 characters in each component, and let *length* be 8.

14. While *length* is greater than two and the first character in each component is a U+0030 DIGIT ZERO (0) character, remove that character and reduce *length* by one.
15. If *length* is still greater than two, truncate each component, leaving only the first two characters in each.
16. Let *result* be a [simple colour](#)^{b78}.
17. Interpret the first component as a hexadecimal number; let the red component of *result* be the resulting number.
18. Interpret the second component as a hexadecimal number; let the green component of *result* be the resulting number.
19. Interpret the third component as a hexadecimal number; let the blue component of *result* be the resulting number.
20. Return *result*.

Note *The 2D graphics context*^{b610} has a separate colour syntax that also handles opacity.

2.4.7 Space-separated tokens

A **set of space-separated tokens** is a string containing zero or more words (known as tokens) separated by one or more [space characters](#)^{b58}, where words consist of any string of one or more characters, none of which are [space characters](#)^{b58}.

A string containing a [set of space-separated tokens](#)^{b80} may have leading or trailing [space characters](#)^{b58}.

An **unordered set of unique space-separated tokens** is a [set of space-separated tokens](#)^{b80} where none of the tokens are duplicated.

An **ordered set of unique space-separated tokens** is a [set of space-separated tokens](#)^{b80} where none of the tokens are duplicated but where the order of the tokens is meaningful.

[Sets of space-separated tokens](#)^{b80} sometimes have a defined set of allowed values. When a set of allowed values is defined, the tokens must all be from that list of allowed values; other values are non-conforming. If no such set of allowed values is provided, then all values are conforming.

Note How tokens in a [set of space-separated tokens](#)^{b80} are to be compared (e.g. case-sensitively or not) is defined on a per-set basis.

When a user agent has to **split a string on spaces**, it must use the following algorithm:

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Let *tokens* be an ordered list of tokens, initially empty.
4. [Skip whitespace](#)^{b59}
5. While *position* is not past the end of *input*:
 1. [Collect a sequence of characters](#)^{b59} that are not [space characters](#)^{b58}.
 2. Append the string collected in the previous step to *tokens*.
 3. [Skip whitespace](#)^{b59}
6. Return *tokens*.

2.4.8 Comma-separated tokens

A **set of comma-separated tokens** is a string containing zero or more tokens each separated from the next by a single U+002C COMMA character (,), where tokens consist of any string of zero or more characters, neither beginning nor ending with [space characters](#)^{b58}, nor containing any U+002C COMMA characters (,), and optionally surrounded by [space characters](#)^{b58}.

Example For instance, the string "`a ,b,,d d`" consists of four tokens: "a", "b", the empty string, and "d d". Leading and trailing whitespace around each token doesn't count as part of the token, and the empty string can be a token.

Sets of comma-separated tokens^{p80} sometimes have further restrictions on what counts as a valid token. When such restrictions are defined, the tokens must all fit within those restrictions; other values are non-conforming. If no such restrictions are specified, then all values are conforming.

When a user agent has to **split a string on commas**, it must use the following algorithm:

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Let *tokens* be an ordered list of tokens, initially empty.
4. *Token*: If *position* is past the end of *input*, jump to the last step.
5. [Collect a sequence of characters^{p59}](#) that are not U+002C COMMA characters (,). Let *s* be the resulting sequence (which might be the empty string).
6. [Strip leading and trailing whitespace^{p59}](#) from *s*.
7. Append *s* to *tokens*.
8. If *position* is not past the end of *input*, then the character at *position* is a U+002C COMMA character (,); advance *position* past that character.
9. Jump back to the step labeled *token*.
10. Return *tokens*.

2.4.9 References

A **valid hash-name reference** to an element of type *type* is a string consisting of a U+0023 NUMBER SIGN character (#) followed by a string which exactly matches the value of the `name` attribute of an element with type *type* in the document.

The **rules for parsing a hash-name reference** to an element of type *type*, given a context node *scope*, are as follows:

1. If the string being parsed does not contain a U+0023 NUMBER SIGN character, or if the first such character in the string is the last character in the string, then return null and abort these steps.
2. Let *s* be the string from the character immediately after the first U+0023 NUMBER SIGN character in the string being parsed up to the end of that string.
3. Return the first element of type *type* in [tree order^{p42}](#) in the subtree rooted at *scope* that has an [`id`^{p122}](#) attribute whose value is a [case-sensitive^{p58}](#) match for *s* or a `name` attribute whose value is a [compatibility caseless^{p58}](#) match for *s*.

2.4.10 Media queries

A string is a **valid media query list** if it matches the `<media-query-list>` production of the Media Queries specification. [`\[MQ\]`^{p1151}](#)

A string **matches the environment** of the user if it is the empty string, a string consisting of only [space characters^{p58}](#), or is a media query list that matches the user's environment according to the definitions given in the Media Queries specification. [`\[MQ\]`^{p1151}](#)

2.5 URLs

2.5.1 Terminology

A [`URL`^{p48}](#) is a **valid URL** if it conforms to the authoring conformance requirements in the WHATWG URL standard. [`\[URL\]`^{p1153}](#)

A string is a **valid non-empty URL** if it is a [valid URL^{p81}](#) but it is not the empty string.

A string is a **valid URL potentially surrounded by spaces** if, after [stripping leading and trailing whitespace^{p59}](#) from it, it is a [valid URL^{p81}](#).

A string is a **valid non-empty URL potentially surrounded by spaces** if, after [stripping leading and trailing whitespace^{p59}](#) from it, it is a [valid non-empty URL^{p82}](#).

This specification defines the URL `about:legacy-compat` as a reserved, though unresolvable, [about:](#) URL, for use in [DOCTYPE^{p941}](#)s in [HTML documents^{p51}](#) when needed for compatibility with XML tools. [\[ABOUT\]^{p1148}](#)

This specification defines the URL `about:srcdoc` as a reserved, though unresolvable, [about:](#) URL, that is used as [the document's address](#) of [iframe srcdoc documents^{p300}](#). [\[ABOUT\]^{p1148}](#)

The **fallback base URL** of a [Document^{p102}](#) object is the [absolute URL^{p48}](#) obtained by running these substeps:

1. If the [Document^{p102}](#) is an [iframe srcdoc document^{p300}](#), then return the [document base URL^{p82}](#) of the [Document^{p102}](#)'s [browsing context^{p762}](#)'s [browsing context container^{p763}](#)'s [node document](#) and abort these steps.
2. If [the document's address](#) is [about:blank^{p84}](#), and the [Document^{p102}](#)'s [browsing context^{p762}](#) has a [creator browsing context^{p762}](#), then return the [document base URL^{p82}](#) of the [creator Document^{p762}](#), and abort these steps.
3. Return [the document's address](#).

The **document base URL** of a [Document^{p102}](#) object is the [absolute URL^{p48}](#) obtained by running these substeps:

1. If there is no [base^{p140}](#) element that has an [href^{p140}](#) attribute in the [Document^{p102}](#), then the [document base URL^{p82}](#) is the [Document^{p102}](#)'s [fallback base URL^{p82}](#); abort these steps.
2. Otherwise, the [document base URL^{p82}](#) is the [frozen base URL^{p140}](#) of the first [base^{p140}](#) element in the [Document^{p102}](#) that has an [href^{p140}](#) attribute, in [tree order^{p42}](#).

2.5.2 Resolving URLs

Resolving a URL is the process of taking a [relative URL^{p48}](#) and obtaining the [absolute URL^{p48}](#) that it implies.

To **resolve a URL** to an [absolute URL^{p48}](#) relative to either another [absolute URL^{p48}](#) or an element, the user agent must use the following steps. Resolving a URL can result in an error, in which case the URL is not resolvable.

1. Let *url* be the [URL^{p48}](#) being resolved.
2. Let *encoding* be determined as follows:
 - ↪ If the URL had a character encoding defined when the URL was created or defined or when this algorithm was invoked
The URL character encoding is as defined.
 - ↪ If the URL came from a script (e.g. as an argument to a method)
The URL character encoding is the [API URL character encoding^{p829}](#) specified by the script's [settings object^{p829}](#).
 - ↪ If the URL came from a DOM node (e.g. from an element)
The node has a [Document^{p102}](#), and the URL character encoding is the [document's character encoding^{p51}](#).
3. If *encoding* is a [UTF-16 encoding^{p44}](#), then change the value of *encoding* to UTF-8.
4. If the algorithm was invoked with an [absolute URL^{p48}](#) to use as the base URL, let *base* be that [absolute URL^{p48}](#).
Otherwise, let *base* be [the element's base URL^{p83}](#).
5. Apply the [URL parser^{p48}](#) to *url*, with *base* as the base URL, with *encoding* as the encoding.
6. If this returns failure, then abort these steps with an error.
7. Let *parsed URL* be the result of the [URL parser^{p48}](#).

8. Let *serialised URL* be the result of apply the [URL serialiser^{p48}](#) to *parsed URL*.
9. Return *serialised URL* as the **resulting absolute URL** and *parsed URL* as the **resulting parsed URL**.

Given an element, **the element's base URL** is the *base URI of the element*, as defined by the XML Base specification, with *the base URI of the document entity* being defined as the [document base URL^{p82}](#) of the [Document^{p102}](#) that owns the element. [\[XMLBASE\]^{p1154}](#) Spec bugs: [20976](#) :

For the purposes of the XML Base specification, user agents must act as if all [Document^{p102}](#) objects represented XML documents.

Note It is possible for [xml:base^{p125}](#) attributes to be present even in HTML fragments, as such attributes can be added dynamically using script. (Such scripts would not be conforming, however, as [xml:base^{p125}](#) attributes are not allowed in [HTML documents^{p51}](#).)

2.5.3 Dynamic changes to base URLs

When an [xml:base^{p125}](#) attribute is set, changed, or removed, the attribute's element, and all descendant elements, are [affected by a base URL change^{p51}](#).

When a document's [document base URL^{p82}](#) changes, all elements in that document are [affected by a base URL change^{p51}](#).

The following are [base URL change steps^{p51}](#), which run when an element is [affected by a base URL change^{p51}](#) (as defined by the DOM specification):

↪ If the element creates a [hyperlink^{p245}](#)

If the [absolute URL^{p48}](#) identified by the hyperlink is being shown to the user, or if any data derived from that URL is affecting the display, then the [href^{p245}](#) attribute should be [re-resolved^{p82}](#) relative to the element and the UI updated appropriately.

Example For example, the CSS [:link^{p679}/\[:visited^{p679}\]\(#\) pseudo-classes might have been affected.](#)

If the hyperlink has a [ping^{p246}](#) attribute and its [absolute URL\(s\)^{p48}](#) are being shown to the user, then the [ping^{p246}](#) attribute's tokens should be [re-resolved^{p82}](#) relative to the element and the UI updated appropriately.

↪ If the element is a [a^{p215}](#), [blockquote^{b193}](#), [ins^{b260}](#), or [del^{b262}](#) element with a [cite](#) attribute

If the [absolute URL^{p48}](#) identified by the [cite](#) attribute is being shown to the user, or if any data derived from that URL is affecting the display, then the [URL^{p48}](#) should be [re-resolved^{p82}](#) relative to the element and the UI updated appropriately.

↪ Otherwise

The element is not directly affected.

Example For instance, changing the base URL doesn't affect the image displayed by [img^{p272}](#) elements, although subsequent accesses of the [src^{p285}](#) IDL attribute from script will return a new [absolute URL^{p48}](#) that might no longer correspond to the image being shown.

2.6 Fetching resources

2.6.1 Terminology

User agents can implement a variety of transfer protocols, but this specification mostly defines behaviour in terms of HTTP. [\[HTTP\]^{p1150}](#)

The **HTTP GET method** is equivalent to the default retrieval action of the protocol. For example, RETR in FTP. Such actions are idempotent and safe, in HTTP terms.

The **HTTP response codes** are equivalent to statuses in other protocols that have the same basic meanings. For example, a "file not found" error is equivalent to a 404 code, a server error is equivalent to a 5xx code, and so on.

The **HTTP headers** are equivalent to fields in other protocols that have the same basic meaning. For example, the HTTP authentication headers are equivalent to the authentication aspects of the FTP protocol.

2.6.2 Processing model

Spec bugs: 24613, 24659

When a user agent is to **fetch** a resource or [URL^{p48}](#), optionally **from** an origin [origin^{p102}](#), optionally **using** a specific [Document^{p102}](#) or a specific [URL^{p48}](#) as an *override referrer source*, and optionally with any of a *blocking flag*, a *manual redirect flag*, a *force same-origin flag*, and a *block cookies flag* the following steps must be run. (When a [URL^{p48}](#) is to be fetched, the URL identifies a resource to be obtained.)

Spec bugs: 11235

1. If there is a specific *override referrer source*, and it is a [URL^{p48}](#), then let *referrer* be the *override referrer source*, and jump to the step labeled *clean referrer*.
2. Let *document* be the appropriate [Document^{p102}](#) as given by the following list:
 - ↪ If there is a specific *override referrer source* (which might be null)
The *override referrer source*.
 - ↪ When [navigating^{p791}](#)
The [active document^{p762}](#) of the [source browsing context^{p791}](#).
 - ↪ When fetching resources for an element
The element's [node document](#).
3. While *document* is [an iframe srcdoc document^{p300}](#), let *document* be *document*'s [browsing context^{p762}](#)'s [browsing context container^{p763}](#)'s [node document](#) instead.
4. If *document* is null, or if the [origin^{p776}](#) of *document* is not a scheme/host/port tuple, then set *referrer* to the empty string and jump to the step labeled *cleaned referrer*.
5. Let *referrer* be [the document's address](#) of *document*.
6. *Clean referrer*: Apply the [URL parser^{p48}](#) to *referrer* and let *parsed referrer* be the [resulting parsed URL^{p83}](#).
7. Let *referrer* be the result of applying the [URL serialiser^{p48}](#) to *parsed referrer*, with the *exclude fragment flag* set.
8. *Cleaned referrer*: If *referrer* is not the empty string, is not a [data: URL](#), and is not the [URL^{p48} "about:blank^{p84}"](#), then generate the *address of the resource from which Request-URIs are obtained* as required by HTTP for the [Referer^{p49}](#) (sic) header from *referrer*.
[\[HTTP\]^{p1150}](#)
Otherwise, the [Referer^{p49}](#) (sic) header must be omitted, regardless of its value.
9. If the algorithm was not invoked with the *blocking flag*, perform the remaining steps [in parallel^{p41}](#).
10. If the [Document^{p102}](#) with which any [tasks^{p834} queued^{p835}](#) by this algorithm would be associated doesn't have an associated [browsing context^{p762}](#), then abort these steps.
11. This is the *main step*.

If the resource is to be obtained from an [application cache^{p809}](#), then use the data from that [application cache^{p809}](#), as if it had been obtained in the manner appropriate given its [URL^{p48}](#).

If the resource is identified by an [absolute URL^{p48}](#), and the resource is to be obtained using an idempotent action (such as an HTTP GET [or equivalent^{p83}](#)), and it is already being downloaded for other reasons (e.g. another invocation of this algorithm), and this request would be identical to the previous one (e.g. same [Accept^{p48}](#) and [Origin^{p49}](#) headers), and the user agent is configured such that it is to reuse the data from the existing download instead of initiating a new one, then use the results of the existing download instead of starting a new one.

Otherwise, if the resource is identified by an [absolute URL^{p48}](#) with a scheme that does not define a mechanism to obtain the resource (e.g. it is a [mailto:](#) URL) or that the user agent does not support, then act as if the resource was an HTTP 204 No Content response with no other metadata.

Otherwise, if the resource is identified by the [URL^{p48} about:blank](#), then the resource is immediately available and consists of the empty string, with no metadata.

Otherwise, at a time convenient to the user and the user agent, download (or otherwise obtain) the resource, applying the semantics of the relevant specifications (e.g. performing an HTTP GET or POST operation, or reading the file from disk, or expanding [data: URLs](#), etc.).

For the purposes of the [Referer](#)^{p49} (sic) header, use the *address of the resource from which Request-URIs are obtained* generated in the earlier step.

For the purposes of the [Origin](#)^{p49} header, if the [fetching algorithm](#)^{p84} was explicitly initiated from an *origin*, then *the origin that initiated the HTTP request is origin*. Otherwise, this is a *request from a "privacy-sensitive" context*. [\[ORIGIN\]](#)^{p1151}

12. If the algorithm was not invoked with the *block cookies flag*, and there are cookies to be set, then the user agent must run the following substeps:

1. Wait until ownership of the [storage mutex](#)^{p835} can be taken by this instance of the [fetching](#)^{p84} algorithm.
2. Take ownership of the [storage mutex](#)^{p835}.
3. Update the cookies. [\[COOKIES\]](#)^{p1148}
4. Release the [storage mutex](#)^{p835} so that it is once again free.

13. If the fetched resource is an HTTP redirect [or equivalent](#)^{p83}, then:

↪ If the *force same-origin flag* is set and the [URL](#)^{p48} of the target of the redirect does not have the [same origin](#)^{p778} as the [URL](#)^{p48} for which the [fetch](#)^{p84} algorithm was invoked

Abort these steps and return failure from this algorithm, as if the remote host could not be contacted.

↪ If the *manual redirect flag* is set

Continue, using the fetched resource (the redirect) as the result of the algorithm. If the calling algorithm subsequently requires the user agent to *transparently follow the redirect*, then the user agent must resume this algorithm from the *main step*, but using the target of the redirect as the resource to fetch, rather than the original resource.

↪ Otherwise

First, apply any relevant requirements for redirects (such as showing any appropriate prompts). Then, redo *main step*, but using the target of the redirect as the resource to fetch, rather than the original resource. For HTTP requests, the new request must include the same headers as the original request, except for headers for which other requirements are specified (such as the [Host](#)^{p49} header). [\[HTTP\]](#)^{p1150}

Note *The HTTP specification requires that 301, 302, and 307 redirects, when applied to methods other than the safe methods, not be followed without user confirmation. That would be an appropriate prompt for the purposes of the requirement in the paragraph above.* [\[HTTP\]](#)^{p1150}

14. If the algorithm was not invoked with the *blocking flag*: When the resource is available, or if there is an error of some description, [queue a task](#)^{p835} that uses the resource as appropriate. If the resource can be processed incrementally, as, for instance, with a progressively interlaced JPEG or an HTML file, additional tasks may be queued to process the data as it is downloaded. The [task source](#)^{p835} for these [tasks](#)^{p834} is the [networking task source](#)^{p839}.

Otherwise, return the resource or error information to the calling algorithm.

If the user agent can determine the actual length of the resource being [fetched](#)^{p84} for an instance of this algorithm, and if that length is finite, then that length is the file's [size](#). Otherwise, the subject of the algorithm (that is, the resource being fetched) has no known [size](#)^{p85}. (For example, the HTTP [Content-Length](#)^{p49} header might provide this information.)

The user agent must also keep track of the **number of bytes downloaded** for each instance of this algorithm. This number must exclude any out-of-band metadata, such as HTTP headers.

Note *The application cache*^{p809} processing model introduces some [changes to the networking model](#)^{p823} to handle the returning of cached resources.

Note *The navigation*^{p791} processing model handles redirects itself, overriding the redirection handling that would be done by the fetching algorithm.

Note *Whether the type sniffing rules*^{p86} apply to the fetched resource depends on the algorithm that invokes the rules — they are not always applicable.

p30

2.6.3 Encrypted HTTP and related security concerns

Anything in this specification that refers to HTTP also applies to HTTP-over-TLS, as represented by [URLs^{p48}](#) using the [https:](https://) scheme. [\[HTTP\]^{p150}](#)

⚠️Warning! *User agents should report certificate errors to the user and must either refuse to download resources sent with erroneous certificates or must act as if such resources were in fact served with no encryption.*

User agents should warn the user that there is a potential problem whenever the user visits a page that the user has previously visited, if the page uses less secure encryption on the second visit.

Not doing so can result in users not noticing man-in-the-middle attacks.

Example

If a user connects to a server with a self-signed certificate, the user agent could allow the connection but just act as if there had been no encryption. If the user agent instead allowed the user to override the problem and then displayed the page as if it was fully and safely encrypted, the user could be easily tricked into accepting man-in-the-middle connections.

If a user connects to a server with full encryption, but the page then refers to an external resource that has an expired certificate, then the user agent will act as if the resource was unavailable, possibly also reporting the problem to the user. If the user agent instead allowed the resource to be used, then an attacker could just look for "secure" sites that used resources from a different host and only apply man-in-the-middle attacks to that host, for example taking over scripts in the page.

If a user bookmarks a site that uses a CA-signed certificate, and then later revisits that site directly but the site has started using a self-signed certificate, the user agent could warn the user that a man-in-the-middle attack is likely underway, instead of simply acting as if the page was not encrypted.

2.6.4 Determining the type of a resource

The **Content-Type metadata** of a resource must be obtained and interpreted in a manner consistent with the requirements of the MIME Sniffing specification. [\[MIMESNIFF\]^{p151}](#)

The **sniffed type of a resource** must be found in a manner consistent with the requirements given in the MIME Sniffing specification for finding the *sniffed media type* of the relevant sequence of octets. [\[MIMESNIFF\]^{p151}](#)

The [rules for sniffing images specifically](#), the [rules for distinguishing if a resource is text or binary](#), and the [rules for sniffing audio and video specifically](#) are also defined in the MIME Sniffing specification. These rules return a [MIME type^{p42}](#) as their result. [\[MIMESNIFF\]^{p151}](#)

⚠️Warning! *It is imperative that the rules in the MIME Sniffing specification be followed exactly. When a user agent uses different heuristics for content type detection than the server expects, security problems can occur. For more details, see the MIME Sniffing specification. [\[MIMESNIFF\]^{p151}](#)*

2.6.5 Extracting character encodings from [meta^{p145}](#) elements

The **algorithm for extracting a character encoding from a [meta](#) element**, given a string *s*, is as follows. It either returns a character encoding or nothing.

1. Let *position* be a pointer into *s*, initially pointing at the start of the string.
2. *Loop*: Find the first seven characters in *s* after *position* that are an [ASCII case-insensitive^{p58}](#) match for the word "charset". If no such match is found, return nothing and abort these steps.
3. Skip any [space characters^{p58}](#) that immediately follow the word "charset" (there might not be any).
4. If the next character is not a U+003D EQUALS SIGN (=), then move *position* to point just before that next character, and jump back to the step labeled *loop*.
5. Skip any [space characters^{p58}](#) that immediately follow the equals sign (there might not be any).

6. Process the next character as follows:

↪ If it is a U+0022 QUOTATION MARK character ("") and there is a later U+0022 QUOTATION MARK character ("") in s

↪ If it is a U+0027 APOSTROPHE character ('') and there is a later U+0027 APOSTROPHE character ('') in s

Return the result of [getting an encoding](#) from the substring that is between this character and the next earliest occurrence of this character.

↪ If it is an unmatched U+0022 QUOTATION MARK character ("")

↪ If it is an unmatched U+0027 APOSTROPHE character ('')

↪ If there is no next character

Return nothing.

↪ Otherwise

Return the result of [getting an encoding](#) from the substring that consists of this character up to but not including the first [space character](#)^{p58} or U+003B SEMICOLON character (;), or the end of s, whichever comes first.

Note This algorithm is distinct from those in the HTTP specification (for example, HTTP doesn't allow the use of single quotes and requires supporting a backslash-escape mechanism that is not supported by this algorithm). While the algorithm is used in contexts that, historically, were related to HTTP, the syntax as supported by implementations diverged some time ago. [[HTTP](#)]^{p1150}

Spec bugs: [24031](#)

2.6.6 CORS settings attributes

A **CORS settings attribute** is an [enumerated attribute](#)^{p60}. The following table lists the keywords and states for the attribute — the keywords in the left column map to the states in the cell in the second column on the same row as the keyword.

Keyword	State	Brief description
anonymous	Anonymous	Cross-origin CORS requests for the element will have the omit credentials flag ^{p49} set.
use-credentials	Use Credentials	Cross-origin CORS requests for the element will not have the omit credentials flag ^{p49} set.

The empty string is also a valid keyword, and maps to the [Anonymous](#)^{p87} state. The attribute's [invalid value default](#)^{p60} is the [Anonymous](#)^{p87} state. For the purposes of [reflection](#)^{p88}, the canonical case for the [Anonymous](#)^{p87} state is the [anonymous](#)^{p87} keyword. The [missing value default](#)^{p60}, used when the attribute is omitted, is the **No CORS** state.

2.6.7 CORS-enabled fetch

When the user agent is required to perform a **potentially CORS-enabled fetch** of an [absolute URL](#)^{p48} URL with a mode mode that is either "[No CORS](#)^{p87}", "[Anonymous](#)^{p87}", or "[Use Credentials](#)^{p87}", optionally using a specific [Document](#)^{p102} or specific [URL](#)^{p48} referrer source, with an [origin](#)^{p776} origin, and with a default origin behaviour default which is either "taint" or "fail", it must run the first applicable set of steps from the following list. The default origin behaviour is only used if mode is "[No CORS](#)^{p87}". This algorithm wraps the [fetch](#)^{p84} algorithm above, and labels the obtained resource as either **CORS-same-origin** or **CORS-cross-origin**, or blocks the resource entirely.

↪ If the URL has the [same origin](#)^{p778} as origin

↪ If the URL is a [data:](#) URL

↪ If the URL is [about:blank](#)^{p84}

Run these substeps:

1. [Fetch](#)^{p84} URL, using referrer source if one was specified, with the manual redirect flag set.

2. Loop: Wait for the [fetch](#)^{p84} algorithm to know if the result is a redirect or not.

3. Follow the first appropriate steps from the following list:

↪ If the result of the [fetch](#)^{p84} is a redirect, and the [origin](#)^{p776} of the target URL of the redirect is not the [same origin](#)^{p778} as origin

Set URL to the target URL of the redirect and return to the top of the [potentially CORS-enabled fetch](#)^{p87} algorithm (this time, one of the other branches below might be taken, based on the value of mode).

↪ If the result of the [fetch^{p84}](#) is a redirect

Note The [origin^{p776}](#) of the target URL of the redirect is the [same origin^{p778}](#) as origin.

Transparently follow the [redirect^{p85}](#) and jump to the step labeled *loop* above.

↪ Otherwise

Note The resource is available, it is not a redirect, and its [origin^{p776}](#) is the [same origin^{p778}](#) as origin.

The [tasks^{p834}](#) from the [fetch^{p84}](#) algorithm are [queued^{p835}](#) normally, and for the purposes of the calling algorithm, the obtained resource is [CORS-same-origin^{p87}](#).

↪ If mode is "[No CORS^{p87}](#)" and default is taint

Note The URL does not have the [same origin^{p778}](#) as origin.

[Fetch^{p84}](#) URL, using referrer source if one was specified.

The [tasks^{p834}](#) from the [fetch^{p84}](#) algorithm are [queued^{p835}](#) normally, but for the purposes of the calling algorithm, the obtained resource is [CORS-cross-origin^{p87}](#). The user agent may report a cross-origin resource access failure to the user (e.g. in a debugging console).

↪ If mode is "[No CORS^{p87}](#)"

Note The URL does not have the [same origin^{p778}](#) as origin, and default is fail.

Discard any data fetched as part of this algorithm, and prevent any [tasks^{p834}](#) from such invocations of the [fetch^{p84}](#) algorithm from being [queued^{p835}](#). For the purposes of the calling algorithm, the user agent must act as if there was a fatal network error and no resource was obtained. The user agent may report a cross-origin resource access failure to the user (e.g. in a debugging console).

↪ If mode is "[Anonymous^{p87}](#)" or "[Use Credentials^{p87}](#)"

Note The URL does not have the [same origin^{p778}](#) as origin.

Run these steps:

1. Perform a [cross-origin request^{p49}](#) with the *request URL* set to *URL*, with the CORS referrer source set to *referrer source* if one was specified, the *source origin* set to *origin*, and with the [omit credentials flag^{p49}](#) set if mode is "[Anonymous^{p87}](#)" and not set otherwise. [[FETCHI^{p1150}](#)]
2. Wait for the CORS [cross-origin request status^{p49}](#) to have a value.
3. Jump to the appropriate step from the following list:

↪ If the CORS [cross-origin request status^{p49}](#) is not success

Discard all fetched data and prevent any [tasks^{p834}](#) from the [fetch^{p84}](#) algorithm from being [queued^{p835}](#). For the purposes of the calling algorithm, the user agent must act as if there was a fatal network error and no resource was obtained. If a CORS [resource sharing check^{p49}](#) failed, the user agent may report a cross-origin resource access failure to the user (e.g. in a debugging console).

↪ If the CORS [cross-origin request status^{p49}](#) is success

The [tasks^{p834}](#) from the [fetch^{p84}](#) algorithm are [queued^{p835}](#) normally, and for the purposes of the calling algorithm, the obtained resource is [CORS-same-origin^{p87}](#).

2.7 Common DOM interfaces

2.7.1 Reflecting content attributes in IDL attributes

Spec bugs: [20660](#)

Some IDL attributes are defined to reflect a particular content attribute. This means that on getting, the IDL attribute returns the current value of the content attribute, and on setting, the IDL attribute changes the value of the content attribute to the given value.

In general, on getting, if the content attribute is not present, the IDL attribute must act as if the content attribute's value is the empty string; and on setting, if the content attribute is not present, it must first be added.

If a reflecting IDL attribute is a [DOMString^{p49}](#) attribute whose content attribute is defined to contain a [URL^{p48}](#), then on getting, the IDL attribute must [resolve^{p82}](#) the value of the content attribute relative to the element and return the resulting [absolute URL^{p48}](#) if that was successful, or the empty string otherwise; and on setting, must set the content attribute to the specified literal value. If the content attribute is absent, the IDL attribute must return the default value, if the content attribute has one, or else the empty string.

If a reflecting IDL attribute is a [DOMString^{p49}](#) attribute whose content attribute is defined to contain one or more [URLs^{p48}](#), then on getting, the IDL attribute must [split the content attribute on spaces^{p80}](#) and return the concatenation of [resolving^{p82}](#) each token URL to an [absolute URL^{p48}](#) relative to the element, with a single U+0020 SPACE character between each URL, ignoring any tokens that did not resolve successfully. If the content attribute is absent, the IDL attribute must return the default value, if the content attribute has one, or else the empty string. On setting, the IDL attribute must set the content attribute to the specified literal value.

If a reflecting IDL attribute is a [DOMString^{p49}](#) attribute whose content attribute is an [enumerated attribute^{p60}](#), and the IDL attribute is **limited to only known values**, then, on getting, the IDL attribute must return the conforming value associated with the state the attribute is in (in its canonical case), if any, or the empty string if the attribute is in a state that has no associated keyword value or if the attribute is not in a defined state (e.g. the attribute is missing and there is no [missing value default^{p60}](#)); and on setting, the content attribute must be set to the specified new value.

If a reflecting IDL attribute is a nullable [DOMString^{p49}](#) attribute whose content attribute is an [enumerated attribute^{p60}](#), then, on getting, if the corresponding content attribute is in its [missing value default](#) then the IDL attribute must return null, otherwise, the IDL attribute must return the conforming value associated with the state the attribute is in (in its canonical case); and on setting, if the new value is null, the content attribute must be removed, and otherwise, the content attribute must be set to the specified new value.

If a reflecting IDL attribute is a [DOMString^{p49}](#) attribute but doesn't fall into any of the above categories, then the getting and setting must be done in a transparent, case-preserving manner.

If a reflecting IDL attribute is a [boolean^{p49}](#) attribute, then on getting the IDL attribute must return true if the content attribute is set, and false if it is absent. On setting, the content attribute must be removed if the IDL attribute is set to false, and must be set to the empty string if the IDL attribute is set to true. (This corresponds to the rules for [boolean content attributes^{p59}](#).)

If a reflecting IDL attribute has a signed integer type ([long^{p49}](#)) then, on getting, the content attribute must be parsed according to the [rules for parsing signed integers^{p60}](#), and if that is successful, and the value is in the range of the IDL attribute's type, the resulting value must be returned. If, on the other hand, it fails or returns an out of range value, or if the attribute is absent, then the default value must be returned instead, or 0 if there is no default value. On setting, the given value must be converted to the shortest possible string representing the number as a [valid integer^{p60}](#) and then that string must be used as the new content attribute value.

If a reflecting IDL attribute has a signed integer type ([long^{p49}](#)) that is **limited to only non-negative numbers** then, on getting, the content attribute must be parsed according to the [rules for parsing non-negative integers^{p61}](#), and if that is successful, and the value is in the range of the IDL attribute's type, the resulting value must be returned. If, on the other hand, it fails or returns an out of range value, or if the attribute is absent, the default value must be returned instead, or -1 if there is no default value. On setting, if the value is negative, the user agent must throw an [IndexSizeError^{p50}](#) exception. Otherwise, the given value must be converted to the shortest possible string representing the number as a [valid non-negative integer^{p61}](#) and then that string must be used as the new content attribute value.

If a reflecting IDL attribute has an *unsigned* integer type ([unsigned long^{p50}](#)) then, on getting, the content attribute must be parsed according to the [rules for parsing non-negative integers^{p61}](#), and if that is successful, and the value is in the range 0 to 2147483647 inclusive, the resulting value must be returned. If, on the other hand, it fails or returns an out of range value, or if the attribute is absent, the default value must be returned instead, or 0 if there is no default value. On setting, first, if the new value is in the range 0 to 2147483647, then let n be the new value, otherwise let n be the default value, or 0 if there is no default value; then, n must be converted to the shortest possible string representing the number as a [valid non-negative integer^{p61}](#) and that string must be used as the new content attribute value.

If a reflecting IDL attribute has an *unsigned* integer type ([unsigned long^{p50}](#)) that is **limited to only non-negative numbers greater than zero**, then the behaviour is similar to the previous case, but zero is not allowed. On getting, the content attribute must first be parsed according to the [rules for parsing non-negative integers^{p61}](#), and if that is successful, and the value is in the range 1 to 2147483647 inclusive, the resulting value must be returned. If, on the other hand, it fails or returns an out of range value, or if the attribute is absent, the default value must be returned instead, or 1 if there is no default value. On setting, if the value is zero, the user agent must throw an [IndexSizeError^{p50}](#) exception. Otherwise, first, if the new value is in the range 1 to 2147483647, then let n be the new value, otherwise let n be the default value, or 1 if there is no default value; then, n must be converted to the shortest possible string representing the number as a [valid non-negative integer^{p61}](#) and that string must be used as the new content attribute value.

If a reflecting IDL attribute has a floating-point number type ([double^{p49}](#) or [unrestricted double^{p50}](#)), then, on getting, the content attribute must be parsed according to the [rules for parsing floating-point number values^{p62}](#), and if that is successful, the resulting value must be returned. If, on the other hand, it fails, or if the attribute is absent, the default value must be returned instead, or 0.0 if there is no default value. On setting, the given value must be converted to the [best representation of the number as a floating-point number^{p62}](#) and then that string must be used as the new content attribute value.

If a reflecting IDL attribute has a floating-point number type ([double^{p49}](#) or [unrestricted double^{p50}](#)) that is **limited to numbers greater than zero**, then the behaviour is similar to the previous case, but zero and negative values are not allowed. On getting, the content attribute must be parsed according to the [rules for parsing floating-point number values^{p62}](#), and if that is successful and the value is greater than 0.0, the resulting

value must be returned. If, on the other hand, it fails or returns an out of range value, or if the attribute is absent, the default value must be returned instead, or 0.0 if there is no default value. On setting, if the value is less than or equal to zero, then the value must be ignored. Otherwise, the given value must be converted to the [best representation of the number as a floating-point number](#)^{p62} and then that string must be used as the new content attribute value.

Note *The values Infinity and Not-a-Number (NaN) values throw an exception on setting, as defined in the Web IDL specification. [WEBIDL]^{p114}*

If a reflecting IDL attribute has the type [DOMTokenList](#)^{p51} or [DOMSettableTokenList](#)^{p51}, then on getting it must return a [DOMTokenList](#)^{p51} or [DOMSettableTokenList](#)^{p51} object (as appropriate) whose associated element is the element in question and whose associated attribute's local name is the name of the attribute in question. The same [DOMTokenList](#)^{p51} or [DOMSettableTokenList](#)^{p51} object must be returned every time for each attribute.

If a reflecting IDL attribute has the type [HTMLElement](#)^{p112}, or an interface that descends from [HTMLElement](#)^{p112}, then, on getting, it must run the following algorithm (stopping at the first point where a value is returned):

1. If the corresponding content attribute is absent, then the IDL attribute must return null.
2. Let *candidate* be the element that the [document.getElementById\(\)](#)^{p51} method would find when called on the content attribute's element's [node document](#) if it were passed as its argument the current value of the corresponding content attribute.
3. If *candidate* is null, or if it is not type-compatible with the IDL attribute, then the IDL attribute must return null.
4. Otherwise, it must return *candidate*.

On setting, if the given element has an [id](#)^{p122} attribute, and has the same [home subtree](#)^{p42} as the element of the attribute being set, and the given element is the first element in that [home subtree](#)^{p42} whose [ID](#)^{p51} is the value of that [id](#)^{p122} attribute, then the content attribute must be set to the value of that [id](#)^{p122} attribute. Otherwise, the content attribute must be set to the empty string.

2.7.2 Collections

The [HTMLAllCollection](#)^{p90}, [HTMLFormControlsCollection](#)^{p91}, [HTMLOptionsCollection](#)^{p93}, and [HTMLPropertiesCollection](#)^{p95} interfaces are [collections](#)^{p51} derived from the [HTMLCollection](#)^{p51} interface.

2.7.2.1 The [HTMLAllCollection](#)^{p90} interface

The [HTMLAllCollection](#)^{p90} interface is used for the legacy [document.all](#)^{p114} attribute. It operates similarly to [HTMLCollection](#)^{p51}; the main differences are that its [namedItem\(\)](#)^{p91} method returns an [HTMLCollection](#)^{p51} object when there are multiple matching elements, and that its [item\(\)](#)^{p91} method can be used as a synonym for its [namedItem\(\)](#)^{p91} method.

Note *All [HTMLAllCollection](#)^{p90} objects are rooted at a [Document](#)^{p102} and have a filter that matches all elements, so the elements represented by the collection^{p51} of an [HTMLAllCollection](#)^{p90} object consist of all the descendant elements of the root [Document](#)^{p102}.*

IDL

```
interface HTMLAllCollection : HTMLCollection {  
    // inherits length and 'getter'  
    Element? item(unsigned long index);  
    (HTMLCollection or Element)? item(DOMString name);  
    legacycaller getter (HTMLCollection or Element)? namedItem(DOMString name); // shadows inherited  
    namedItem()  
};
```

Note [collection.length](#)^{p51}

Returns the number of elements in the collection.

element = collection . item^{p91}(index)

collection[index]

Returns the item with index *index* from the collection. The items are sorted in [tree order^{p42}](#).

element = collection . item^{p91}(name)

collection = collection . item^{p91}(name)

element = collection . namedItem^{p91}(name)

collection = collection . namedItem^{p91}(name)

element = collection(name)

collection = collection(name)

collection[name]

Returns the item with [ID^{p51}](#) or name *name* from the collection.

If there are multiple matching items, then an [HTMLCollection^{p51}](#) object containing all those elements is returned.

Only [button^{p495}](#), [form^{p447}](#), [iframe^{p299}](#), [input^{p452}](#), [map^{p389}](#), [meta^{p145}](#), [object^{p310}](#), [select^{p498}](#), and [textarea^{p508}](#) elements can have a name for the purpose of this method; their name is given by the value of their `name` attribute.

The object's [supported property indices^{p49}](#) are as defined for [HTMLCollection^{p51}](#) objects.

The `item()` method, when invoked with a numeric argument, must act like the `item()p51` method inherited from [HTMLCollection^{p51}](#).

The following elements are "all"-named elements: [a^{p208}](#), [applet^{p1101}](#), [button^{p495}](#), [embed^{p307}](#), [form^{p447}](#), [frame^{p1105}](#), [frameset^{p1104}](#), [iframe^{p299}](#), [img^{p272}](#), [input^{p452}](#), [map^{p389}](#), [meta^{p145}](#), [object^{p310}](#), [select^{p498}](#), and [textarea^{p508}](#)

The [supported property names^{p49}](#) consist of the non-empty values of all the `idp122` attributes of all the elements [represented by the collection^{p51}](#), and the non-empty values of all the `name` attributes of all the "all"-named elements^{p91} [represented by the collection^{p51}](#), in [tree order^{p42}](#), ignoring later duplicates, with the `idp122` of an element preceding its `name` if it contributes both, they differ from each other, and neither is the duplicate of an earlier entry.

The properties exposed in this way must be [unenumerable^{p49}](#).

The `item(name)` and `namedItem(name)` methods must act according to the following algorithm:

1. If *name* is the empty string, return null and stop the algorithm.
2. Let *collection* be an [HTMLCollection^{p51}](#) object rooted at the same [Document^{p102}](#) as the [HTMLAllCollection^{p90}](#) object on which the method was invoked, whose filter matches only elements that are either:
 - "all"-named elements^{p91} with a `name` attribute equal to *name*, or,
 - elements with an [ID^{p51}](#) equal to *name*.
3. If, at the time the method is called, there is exactly one node in *collection*, then return that node and stop the algorithm.
4. Otherwise, if, at the time the method is called, *collection* is empty, return null and stop the algorithm.
5. Otherwise, return *collection*.

2.7.2.2 The [HTMLFormControlsCollection^{p91}](#) interface

The [HTMLFormControlsCollection^{p91}](#) interface is used for [collections^{p51}](#) of [listed elements^{p446}](#) in [form^{p447}](#) and [fieldset^{p524}](#) elements.

IDL

```
interface HTMLFormControlsCollection : HTMLCollection {  
    // inherits length and item()  
    legacycaller getter (RadioNodeList or Element)? namedItem(DOMString name); // shadows inherited  
    namedItem()
```

```

};

interface RadioNodeList : NodeList {
    attribute DOMString value;
};

```

Note

collection.length^{p51}

Returns the number of elements in the collection.

element = collection.item^{p51}(index)

collection[index]

Returns the item with index *index* from the collection. The items are sorted in [tree order^{p42}](#).

element = collection.namedItem^{p92}(name)

radioNodeList = collection.namedItem^{p92}(name)

collection[name]

collection(name)

Returns the item with [ID^{p51}](#) or [name^{p529}](#) *name* from the collection.

If there are multiple matching items, then a [RadioNodeList^{p92}](#) object containing all those elements is returned.

radioNodeList.value [= value]

Returns the value of the first checked radio button represented by the object.

Can be set, to check the first radio button with the given value represented by the object.

The object's [supported property indices^{p49}](#) are as defined for [HTMLCollection^{p51}](#) objects.

The [supported property names^{p49}](#) consist of the non-empty values of all the [id^{p122}](#) and [name^{p529}](#) attributes of all the elements [represented by the collection^{p51}](#), in [tree order^{p42}](#), ignoring later duplicates, with the [id^{p122}](#) of an element preceding its [name^{p529}](#) if it contributes both, they differ from each other, and neither is the duplicate of an earlier entry.

The properties exposed in this way must be [unenumerable^{p49}](#).

The [namedItem\(name\)](#) method must act according to the following algorithm:

1. If *name* is the empty string, return null and stop the algorithm.
2. If, at the time the method is called, there is exactly one node in the collection that has either an [id^{p122}](#) attribute or a [name^{p529}](#) attribute equal to *name*, then return that node and stop the algorithm.
3. Otherwise, if there are no nodes in the collection that have either an [id^{p122}](#) attribute or a [name^{p529}](#) attribute equal to *name*, then return null and stop the algorithm.
4. Otherwise, create a new [RadioNodeList^{p92}](#) object representing a [live^{p43}](#) view of the [HTMLFormControlsCollection^{p91}](#) object, further filtered so that the only nodes in the [RadioNodeList^{p92}](#) object are those that have either an [id^{p122}](#) attribute or a [name^{p529}](#) attribute equal to *name*. The nodes in the [RadioNodeList^{p92}](#) object must be sorted in [tree order^{p42}](#).
5. Return that [RadioNodeList^{p92}](#) object.

Members of the [RadioNodeList^{p92}](#) interface inherited from the [NodeList^{p51}](#) interface must behave as they would on a [NodeList^{p51}](#) object.

The [value](#) IDL attribute on the [RadioNodeList^{p92}](#) object, on getting, must return the value returned by running the following steps:

1. Let *element* be the first element in [tree order^{p42}](#) represented by the [RadioNodeList^{p92}](#) object that is an [input^{p452}](#) element whose [type^{p454}](#) attribute is in the [Radio Button^{p475}](#) state and whose [checkedness^{p527}](#) is true. Otherwise, let it be null.
2. If *element* is null, return the empty string.

3. If *element* is an element with no `value`^{p457} attribute, return the string "on".
4. Otherwise, return the value of *element*'s `value`^{p457} attribute.

On setting, the `value`^{p92} IDL attribute must run the following steps:

1. If the new value is the string "on": let *element* be the first element in `tree order`^{p42} represented by the `RadioNodeList`^{p92} object that is an `input`^{p452} element whose `type`^{p454} attribute is in the `Radio Button`^{p475} state and whose `value`^{p457} content attribute is either absent, or present and equal to the new value, if any. If no such element exists, then instead let *element* be null.
Otherwise: let *element* be the first element in `tree order`^{p42} represented by the `RadioNodeList`^{p92} object that is an `input`^{p452} element whose `type`^{p454} attribute is in the `Radio Button`^{p475} state and whose `value`^{p457} content attribute is present and equal to the new value, if any. If no such element exists, then instead let *element* be null.
2. If *element* is not null, then set its `checkedness`^{b527} to true.

2.7.2.3 The `HTMLOptionsCollection`^{p93} interface

The `HTMLOptionsCollection`^{p93} interface is used for `collections`^{p51} of `option`^{p505} elements. It is always rooted on a `select`^{p498} element and has attributes and methods that manipulate that element's descendants.

```
IDL interface HTMLOptionsCollection : HTMLCollection {
  // inherits item()
  attribute unsigned long length; // shadows inherited length
  Legacycaller HTMLOptionElement? (DOMString name);
  setter creator void (unsigned long index, HTMLOptionElement? option);
  void add(HTMLOptionElement or HTMLOptGroupElement) element, optional (HTMLElement or long)? before
= null;
  void remove(long index);
  attribute long selectedIndex;
};
```

Note

`collection.length`^{p94} [= *value*]

Returns the number of elements in the collection.

When set to a smaller number, truncates the number of `option`^{p505} elements in the corresponding container.

When set to a greater number, adds new blank `option`^{p505} elements to that container.

`element = collection.item`^{b51}(*index*)

`collection[index]`

Returns the item with index *index* from the collection. The items are sorted in `tree order`^{p42}.

`element = collection.namedItem`^{p94}(*name*)

`nodeList = collection.namedItem`^{p94}(*name*)

`collection[name]`

`collection(name)`

Returns the item with `ID`^{p51} or `name`^{p1097} *name* from the collection.

If there are multiple matching items, then the first is returned.

`collection.add`^{p94}(*element* [, *before*])

Inserts *element* before the node given by *before*.

The *before* argument can be a number, in which case *element* is inserted before the item with that number, or an element from the collection, in which case *element* is inserted before that element.

If *before* is omitted, null, or a number out of range, then *element* will be added at the end of the list.

This method will throw a [HierarchyRequestError^{p50}](#) exception if *element* is an ancestor of the element into which it is to be inserted.

collection.selectedIndex^{p95} [= value]

Returns the index of the first selected item, if any, or -1 if there is no selected item.

Can be set, to change the selection.

The object's [supported property indices^{p49}](#) are as defined for [HTMLCollection^{p51}](#) objects.

On getting, the **length** attribute must return the number of nodes [represented by the collection^{p51}](#).

On setting, the behaviour depends on whether the new value is equal to, greater than, or less than the number of nodes [represented by the collection^{p51}](#) at that time. If the number is the same, then setting the attribute must do nothing. If the new value is greater, then *n* new [option^{p505}](#) elements with no attributes and no child nodes must be appended to the [select^{p498}](#) element on which the [HTMLOptionsCollection^{p93}](#) is rooted, where *n* is the difference between the two numbers (new value minus old value). Mutation events must be fired as if a [DocumentFragment^{p51}](#) containing the new [option^{p505}](#) elements had been inserted. If the new value is lower, then the last *n* nodes in the collection must be removed from their parent nodes, where *n* is the difference between the two numbers (old value minus new value).

Note Setting [length^{p94}](#) never removes or adds any [optgroup^{p504}](#) elements, and never adds new children to existing [optgroup^{p504}](#) elements (though it can remove children from them).

The [supported property names^{p49}](#) consist of the non-empty values of all the [id^{p122}](#) and [name^{p1097}](#) attributes of all the elements [represented by the collection^{p51}](#), in [tree order^{p42}](#), ignoring later duplicates, with the [id^{p122}](#) of an element preceding its [name^{p1097}](#) if it contributes both, they differ from each other, and neither is the duplicate of an earlier entry.

The properties exposed in this way must be [unenumerable^{p49}](#).

The **legacy caller** of the [HTMLOptionsCollection^{p93}](#) interface must act like the [namedItem\(\)^{p51}](#) method on the ancestor [HTMLCollection^{p51}](#) interface.

When the user agent is to **set the value of a new indexed property or set the value of an existing indexed property** for a given property index *index* to a new value *value*, it must run the following algorithm:

1. If *value* is null, invoke the steps for the [remove^{p95}](#) method with *index* as the argument, and abort these steps.
2. Let *length* be the number of nodes [represented by the collection^{p51}](#).
3. Let *n* be *index* minus *length*.
4. If *n* is greater than zero, then [append^{p51}](#) a [DocumentFragment^{b51}](#) consisting of *n*-1 new [option^{p505}](#) elements with no attributes and no child nodes to the [select^{p498}](#) element on which the [HTMLOptionsCollection^{p93}](#) is rooted.
5. If *n* is greater than or equal to zero, [append^{p51}](#) *value* to the [select^{p498}](#) element. Otherwise, [replace^{p51}](#) the *index*th element in the collection by *value*.

The **add(*element*, *before*)** method must act according to the following algorithm:

1. If *element* is an ancestor of the [select^{p498}](#) element on which the [HTMLOptionsCollection^{p93}](#) is rooted, then throw a [HierarchyRequestError^{p50}](#) exception and abort these steps.
2. If *before* is an element, but that element isn't a descendant of the [select^{p498}](#) element on which the [HTMLOptionsCollection^{p93}](#) is rooted, then throw a [NotFoundError^{p50}](#) exception and abort these steps.
3. If *element* and *before* are the same element, then return and abort these steps.
4. If *before* is a node, then let *reference* be that node. Otherwise, if *before* is an integer, and there is a *before*th node in the collection, let *reference* be that node. Otherwise, let *reference* be null.
5. If *reference* is not null, let *parent* be the parent node of *reference*. Otherwise, let *parent* be the [select^{p498}](#) element on which the [HTMLOptionsCollection^{p93}](#) is rooted.

6. Act as if the DOM `insertBefore()`^{p51} method was invoked on the *parent* node, with *element* as the first argument and *reference* as the second argument.

The `remove(index)` method must act according to the following algorithm:

1. If the number of nodes `represented by the collection`^{p51} is zero, abort these steps.
2. If *index* is not a number greater than or equal to 0 and less than the number of nodes `represented by the collection`^{p51}, abort these steps.
3. Let *element* be the *index*th element in the collection.
4. Remove *element* from its parent node.

The `selectedIndex` IDL attribute must act like the identically named attribute on the `select`^{p498} element on which the `HTMLOptionsCollection`^{p93} is rooted

2.7.2.4 The `HTMLPropertiesCollection`^{p95} interface

The `HTMLPropertiesCollection`^{p95} interface is used for `collections`^{p51} of elements that add `name-value pairs`^{p694} to a particular `item`^{p689} in the `microdata`^{p683} model.

IDL

```
interface HTMLPropertiesCollection : HTMLCollection {
  // inherits length and item()
  getter PropertyNodeList? namedItem(DOMString name); // shadows inherited namedItem()
  [SameObject] readonly attribute DOMString[] names;
};

typedef sequence<any> PropertyValueArray;

interface PropertyNodeList : NodeList {
  PropertyValueArray getValues();
};
```

Note

`collection.length`^{p51}

Returns the number of elements in the collection.

`element = collection.itemp51(index)`

`collection[index]`

Returns the element with index *index* from the collection. The items are sorted in `tree order`^{p42}.

`propertyNodeList = collection.namedItemp96(name)`

Returns a `PropertyNodeList`^{p95} object containing any elements that add a property named *name*.

`collection[name]`

Returns a `PropertyNodeList`^{p95} object containing any elements that add a property named *name*. The *name* index has to be one of the values listed in the `names`^{p96} list.

`collection.names`^{p96}

Returns an array with the `property names`^{p692} of the elements in the collection.

`propertyNodeList.getValuesp96()`

Returns an array of the various values that the relevant elements have.

The object's `supported property indices`^{p49} are as defined for `HTMLCollection`^{p51} objects.

The [supported property names](#)^{p49} consist of the [property names](#)^{p692} of all the elements [represented by the collection](#)^{p51}, in [tree order](#)^{p42}, ignoring later duplicates.

The properties exposed in this way must be [unenumerable](#)^{p49}.

The [names](#) attribute must return a [live](#)^{p43} [read only](#)^{p49} array object giving the [property names](#)^{p692} of all the elements [represented by the collection](#)^{p51}, listed in [tree order](#)^{p42}, but with duplicates removed, leaving only the first occurrence of each name.

The [namedItem \(name\)](#) method must return a [PropertyNodeList](#)^{p95} object representing a [live](#)^{p43} view of the [HTMLPropertiesCollection](#)^{p95} object, further filtered so that the only nodes in the [PropertyNodeList](#)^{p95} object are those that have a [property name](#)^{p692} equal to *name*. The nodes in the [PropertyNodeList](#)^{p95} object must be sorted in [tree order](#)^{p42}, and the same object must be returned each time a particular *name* is queried from a given [HTMLPropertiesCollection](#)^{p95} object.

Members of the [PropertyNodeList](#)^{p95} interface inherited from the [NodeList](#)^{p51} interface must behave as they would on a [NodeList](#)^{p51} object.

The [getValues](#) method the [PropertyNodeList](#)^{p95} object must return a newly constructed array whose values are the values obtained from the [itemValue](#)^{p696} IDL attribute of each of the elements represented by the object, in [tree order](#)^{p42}.

2.7.3 The [DOMStringMap](#)^{p96} interface

Spec bugs: [28104](#), [28118](#),
[28121](#)

The [DOMStringMap](#)^{p96} interface represents a set of name-value pairs. It exposes these using the scripting language's native mechanisms for property access.

When a [DOMStringMap](#)^{p96} object is instantiated, it is associated with three algorithms, one for getting the list of name-value pairs, one for setting names to certain values, and one for deleting names.

IDL

```
[OverrideBuiltins, Exposed=(Window,Worker)]
interface DOMStringMap {
    getter DOMString (DOMString name);
    setter creator void (DOMString name, DOMString value);
    deleter void (DOMString name);
};
```

The [supported property names](#)^{p49} on a [DOMStringMap](#)^{p96} object at any instant are the names of each pair returned from the algorithm for getting the list of name-value pairs at that instant, in the order returned.

To **determine the value of a named property *name* in a [DOMStringMap](#)^{p96}**, the user agent must return the value component of the name-value pair whose name component is *name* in the list returned by the algorithm for getting the list of name-value pairs.

To set the value of a **new or existing** named property *name* to value *value*, the algorithm for setting names to certain values must be run, passing *name* as the name and the result of converting *value* to a [DOMString](#)^{p49} as the value.

To **delete an existing named property *name***, the algorithm for deleting names must be run, passing *name* as the name.

Note *The [DOMStringMap](#)^{p96} interface definition here is only intended for JavaScript environments. Other language bindings will need to define how [DOMStringMap](#)^{p96} is to be implemented for those languages.*

Example

The [dataset](#)^{p129} attribute on elements exposes the [data-*](#)^{p128} attributes on the element.

Given the following fragment and elements with similar constructions:

```

```

...one could imagine a function `splashDamage()` that takes some arguments, the first of which is the element to process:

```

function splashDamage(node, x, y, damage) {
    if (node.classList.contains('tower') && // checking the 'class' attribute
        node.dataset.x == x && // reading the 'data-x' attribute
        node.dataset.y == y) { // reading the 'data-y' attribute
        var hp = parseInt(node.dataset.hp); // reading the 'data-hp' attribute
        hp = hp - damage;
        if (hp < 0) {
            hp = 0;
            node.dataset.ai = 'dead'; // setting the 'data-ai' attribute
            delete node.dataset.ability; // removing the 'data-ability' attribute
        }
        node.dataset.hp = hp; // setting the 'data-hp' attribute
    }
}

```

2.7.4 DOMElementMap

The [DOMElementMap^{p97}](#) interface represents a set of name-element mappings. It exposes these using the scripting language's native mechanisms for property access.

When a [DOMElementMap^{p97}](#) object is instantiated, it is associated with three algorithms, one for getting the list of name-element mappings, one for mapping a name to a certain element, and one for deleting mappings by name.

IDL

```

interface DOMElementMap {
    getter Element (DOMString name);
    setter creator void (DOMString name, Element value);
    deleter void (DOMString name);
};

```

The [supported property names^{p49}](#) on a [DOMElementMap^{p97}](#) object at any instant are the names for each mapping returned from the algorithm for getting the list of name-element mappings at that instant, in the order returned.

To **determine the value of a named property *name*** in a [DOMElementMap^{p97}](#), the user agent must return the element component of the name-element mapping whose name component is *name* in the list returned by the algorithm for getting the list of name-element mappings.

To set the value of a **new or existing** named property *name* to value *value*, the algorithm for mapping a name to a certain element must be run, passing *name* as the name *value* as the element.

To **delete an existing named property *name***, the algorithm for deleting mappings must be run, passing *name* as the name component of the mapping to be deleted.

Note *The [DOMElementMap^{p97}](#) interface definition here is only intended for JavaScript environments. Other language bindings will need to define how [DOMElementMap^{p97}](#) is to be implemented for those languages.*

2.7.5 Transferable objects

Some objects support being copied and closed in one operation. This is called *transferring* the object, and is used in particular to transfer ownership of unshareable or expensive resources across worker boundaries.

The following [Transferable^{p98}](#) types exist:

- [ArrayBuffer^{p50}](#) [[ECMA262^{p1150}](#)]
- [CanvasProxy^{p611}](#) (defined in this specification)
- [MessagePort^{p904}](#) (defined in this specification)

The following IDL block formalizes this:

IDL `typedef (ArrayBuffer or CanvasProxy or MessagePort) Transferable;`

To transfer a **Transferable** object to a new owner, the user agent must run the steps defined for the type of object in question. The steps will return a new object of the same type, and will permanently **neuter** the original object. (This is an irreversible and non-idempotent operation: once an object has been transferred, it cannot be transferred, or indeed used, again.)

Spec bugs: 27031

To transfer^{p98} an ArrayBuffer^{p50} object *old* to a new owner *owner*, a user agent must create a new ArrayBuffer^{p50} object pointing at the same underlying data as *old*, thus obtaining *new*, must neuter^{p98} the *old* object, and must finally return *new*. [ECMA262]^{p1150}

Note Rules for how to transfer a CanvasProxy object^{p612} and how to transfer a MessagePort object^{p906} are given in the relevant sections of this specification.

Spec bugs: 21652

2.7.6 Safe passing of structured data

When a user agent is required to obtain a **structured clone** of a value, optionally with a *transfer map*, it must run the following algorithm, which either returns a separate value, or throws an exception. If a *transfer map* is provided, it consists of an association list of Transferable^{p98} objects to placeholder objects.

1. Let *input* be the value being cloned.
2. Let *transfer map* be the *transfer map* passed to the algorithm, if any, or the empty list otherwise.
3. Let *memory* be an association list of pairs of objects, initially empty. This is used to handle duplicate references. In each pair of objects, one is called the *source* object and the other the *destination* object.
4. For each mapping in *transfer map*, add a mapping from the Transferable^{p98} object (the source object) to the placeholder object (the destination object) to *memory*.
5. Let *output* be the value resulting from calling the internal structured cloning algorithm^{p98} with *input* as the "input" argument, and *memory* as the "memory" argument.
6. Return *output*.

The **internal structured cloning algorithm** is always called with two arguments, *input* and *memory*, and its behaviour is as follows:

1. If *input* is the source object of a pair of objects in *memory*, then return the destination object in that pair of objects and abort these steps.
2. If *input* is a primitive value, then return that value and abort these steps.
3. Let *deep clone* be *none*.
4. The *input* value is an object. Jump to the appropriate step below:
 - ↪ **If *input* is a Boolean^{p49} object**
Let *output* be a newly constructed Boolean object with the same value as *input*.
 - ↪ **If *input* is a Number^{p49} object**
Let *output* be a newly constructed Number object with the same value as *input*.
 - ↪ **If *input* is a String^{p50} object**
Let *output* be a newly constructed String object with the same value as *input*.
 - ↪ **If *input* is a Date^{p49} object**
Let *output* be a newly constructed Date^{p49} object with the same value as *input*.
 - ↪ **If *input* is a RegExp^{p49} object**
Let *output* be a newly constructed RegExp^{p49} object with the same pattern and flags as *input*.

Note The value of the *lastIndex* property is not copied.

↪ If *input* is a [Blob](#)^{p52} object

If *input* has been disabled through the [close\(\)](#)^{p52} method, throw a [DataCloneError](#)^{p50} exception and abort the overall [structured clone](#)^{p98} algorithm. Otherwise, let *output* be a newly constructed object of the same class as *input*, corresponding to the same underlying data.

↪ If *input* is a [FileList](#)^{p52} object

Let *output* be a newly constructed [FileList](#)^{p52} object containing a list of newly constructed [File](#)^{p52} objects corresponding to the same underlying data as those in *input*, maintaining their relative order.

↪ If *input* is an [ImageData](#)^{p616} object

Let *output* be a newly constructed [ImageData](#)^{p616} object whose [width](#)^{p660} and [height](#)^{p660} have values equal to the corresponding attributes on *input*, and whose [data](#)^{p660} attribute has the value obtained from invoking the [internal structured cloning algorithm](#)^{p98} recursively with the value of the [data](#)^{p660} attribute on *input* as the new "input" argument and *memory* as the new "memory" argument.

↪ If *input* is an [ImageBitmap](#)^{p874} object

Let *output* be a newly constructed [ImageBitmap](#)^{p874} object whose bitmap data is a copy of *input*'s bitmap data.

↪ If *input* is an [ArrayBuffer](#)^{p50} object

If *input* has been [neutered](#)^{p98}, throw a [DataCloneError](#)^{p50} exception and abort the overall [structured clone](#)^{p98} algorithm. Otherwise, let *output* be a newly constructed [ArrayBuffer](#)^{p50} object whose contents are a copy of *input*'s contents, with the same length.

↪ If *input* is an object with a [\[\[DataView\]\]](#) internal slot

Let *output* be a newly constructed object of the same class as *input*, with its [\[\[DataView\]\]](#) internal property present, its [\[\[ViewedArrayBuffer\]\]](#) internal property set to the value obtained from invoking the [internal structured cloning algorithm](#)^{p98} recursively with the value of the internal property on *input* as the new "input" argument and *memory* as the new "memory" argument, and with the [\[\[ByteLength\]\]](#) and [\[\[ByteOffset\]\]](#) internal properties set to the same value as their counterparts on *input*.

↪ If *input* is an [Array](#)^{p49} object

Let *output* be a newly constructed empty [Array](#)^{p49} object whose [length](#) is equal to the [length](#) of *input*, and set *deep clone* to *own*.

Note This means that the length of sparse arrays is preserved.

↪ If *input* is an [Object](#)^{p49} object

Let *output* be a newly constructed empty [Object](#)^{p49} object, and set *deep clone* to *own*.

↪ If *input* is a [Map](#)^{p49} object

Let *output* be a newly constructed empty [Map](#)^{p49} object, and set *deep clone* to *map*.

↪ If *input* is a [Set](#)^{p50} object

Let *output* be a newly constructed empty [Set](#)^{p50} object, and set *deep clone* to *set*.

↪ If *input* is an object that another specification defines how to clone

Let *output* be a clone of the object as defined by the other specification.

↪ If *input* is another native object type (e.g. [Error](#)^{p49}, [Function](#)^{p49})

↪ If *input* is a host object (e.g. a DOM node)

Throw a [DataCloneError](#)^{p50} exception and abort the overall [structured clone](#)^{p98} algorithm.

For the purposes of the algorithm above, an object is a particular type of object *class* if its [\[\[Class\]\]](#) internal property is equal to *class*.

Example For example, "*input* is an [Object](#)^{p49} object" if *input*'s [\[\[Class\]\]](#) internal property is equal to the string "Object".

5. Add a mapping from *input* (the source object) to *output* (the destination object) to *memory*.
6. If *deep clone* is set to *map*, then run these substeps. These substeps use the terminology and typographic conventions used in the JavaScript specification's definition of Maps. [\[ECMA262\]](#)^{p1150}

- Let *source* be the List that is the value of *input*'s `[[MapData]]` internal slot, if any. If there is no such slot, then instead throw a [DataCloneError^{p50}](#) exception and abort the overall [structured clone^{p98}](#) algorithm. [\[ECMA262\]^{p1150}](#)
 - Let *target* be the List that is the value of *output*'s `[[MapData]]` internal slot.
 - For each Record `{[[key]], [[value]]}` *entry* that is an element of *source*, run the following substeps:
 - Let *key* have the value obtained from invoking the [internal structured cloning algorithm^{p98}](#) recursively with *entry.[[key]]* as the new "input" argument and *memory* as the new "memory" argument.
 - Let *value* have the value obtained from invoking the [internal structured cloning algorithm^{p98}](#) recursively with *entry.[[value]]* as the new "input" argument and *memory* as the new "memory" argument.
 - Let *new entry* be the Record `{[[key]]: key, [[value]]: value}`.
 - Append *new entry* as the last element of *target*.
 - Set *deep clone* to *own*.
7. If *deep clone* is set to *set*, then run these substeps. These substeps use the terminology and typographic conventions used in the JavaScript specification's definition of Sets. [\[ECMA262\]^{p1150}](#)
- Let *source* be the List that is the value of *input*'s `[[SetData]]` internal slot, if any. If there is no such slot, then instead throw a [DataCloneError^{p50}](#) exception and abort the overall [structured clone^{p98}](#) algorithm. [\[ECMA262\]^{p1150}](#)
 - Let *target* be the List that is the value of *output*'s `[[SetData]]` internal slot.
 - For each *entry* that is an element of *source* that is not *empty*, run the following substeps:
 - Let *new entry* have the value obtained from invoking the [internal structured cloning algorithm^{p98}](#) recursively with *entry* as the new "input" argument and *memory* as the new "memory" argument.
 - Append *new entry* as the last element of *target*.
 - Set *deep clone* to *own*.
8. If *deep clone* is set to *own*, then, for each enumerable own property in *input*, run the following steps:
- Let *name* be the name of the property.
 - Let *source value* be the result of calling the `[[Get]]` internal method of *input* with the argument *name*. If the `[[Get]]` internal method of a property involved executing script, and that script threw an uncaught exception, then abort the overall [structured clone^{p98}](#) algorithm, with that exception being passed through to the caller.
 - Let *cloned value* be the result of invoking the [internal structured cloning algorithm^{p98}](#) recursively with *source value* as the "input" argument and *memory* as the "memory" argument. If this results in an exception, then abort the overall [structured clone^{p98}](#) algorithm, with that exception being passed through to the caller.
 - Add a new property to *output* having the name *name*, and having the value *cloned value*.

The order of the properties in the *input* and *output* objects must be the same, and any properties whose `[[Get]]` internal method involves running script must be processed in that same order.

Note *This does not walk the prototype chain.*

Note *Property descriptors, setters, getters, and analogous features are not copied in this process. For example, the property in the input could be marked as read-only, but in the output it would just have the default state (typically read-write, though that could depend on the scripting environment).*

Note *Properties of Array objects are not treated any differently than those of other Objects. In particular, this means that non-index properties of arrays are copied as well.*

- Return *output*.

Note *This algorithm preserves cycles and preserves the identity of duplicate objects in graphs.*

2.7.7 Callbacks

The following callback function type is used in various APIs that interact with [File](#)^{p52} objects:

```
IDL   callback FileCallback = void (File file);
```

2.7.8 Garbage collection

There is an **implied strong reference** from any IDL attribute that returns a pre-existing object to that object.

Example

For example, the [document.location](#)^{p788} attribute means that there is a strong reference from a [Document](#)^{p102} object to its [Location](#)^{p788} object. Similarly, there is always a strong reference from a [Document](#)^{p102} to any descendant nodes, and from any node to its owner [Document](#)^{p102}.

2.8 Namespaces

The **HTML namespace** is: <http://www.w3.org/1999/xhtml>

The **MathML namespace** is: <http://www.w3.org/1998/Math/MathML>

The **SVG namespace** is: <http://www.w3.org/2000/svg>

The **XLink namespace** is: <http://www.w3.org/1999/xlink>

The **XML namespace** is: <http://www.w3.org/XML/1998/namespace>

The **XMLNS namespace** is: <http://www.w3.org/2000/xmlns/>

Data mining tools and other user agents that perform operations on content without running scripts, evaluating CSS or XPath expressions, or otherwise exposing the resulting DOM to arbitrary content, may "support namespaces" by just asserting that their DOM node analogues are in certain namespaces, without actually exposing the above strings.

Note In the [HTML syntax](#)^{p941}, namespace prefixes and namespace declarations do not have the same effect as in XML. For instance, the colon has no special meaning in HTML element names.

3 Semantics, structure, and APIs of HTML documents

3.1 Documents

Every XML and HTML document in an HTML UA is represented by a [Document](#) object. [\[DOM\]](#)

[The document's address](#) is the *URL associated with a Document* (as defined in the DOM standard). It is initially set when the [Document](#) is created, but that can change during the lifetime of the [Document](#), for example, it changes when the user [navigates](#) to a [fragment identifier](#) on the page and when the [pushState\(\)](#) method is called with a new [URL](#). [\[DOM\]](#)

⚠ Warning! *Interactive user agents typically expose the document's address in their user interface. This is the primary mechanism by which a user can tell if a site is attempting to impersonate another.*

When a [Document](#) is created by a [script](#) using the [createDocument\(\)](#) or [createHTMLDocument\(\)](#) APIs, [the document's address](#) is the same as [the document's address](#) of the [responsible document](#) specified by the script's [settings object](#), and the [Document](#) is both [ready for post-load tasks](#) and [completely loaded](#) immediately.

[The document's referrer](#) is an [absolute URL](#) that can be set when the [Document](#) is created. If it is not explicitly set, then its value is the empty string.

Each [Document](#) object has a **reload override flag** that is originally unset. The flag is set by the [document.open\(\)](#) and [document.write\(\)](#) methods in certain situations. When the flag is set, the [Document](#) also has a **reload override buffer** which is a Unicode string that is used as the source of the document when it is reloaded.

When the user agent is to perform **an overridden reload**, given a [source browsing context](#), it must act as follows:

1. Let *source* be the value of the [browsing context](#)'s [active document](#)'s [reload override buffer](#).
2. Let *address* be the [browsing context](#)'s [active document](#)'s [address](#).
3. [Navigate](#) the [browsing context](#) to a resource whose source is *source*, with [replacement enabled](#) and [exceptions enabled](#).
The [source browsing context](#) is that given to the [overridden reload](#) algorithm. When the [navigate](#) algorithm creates a [Document](#) object for this purpose, set that [Document](#)'s [reload override flag](#) and set its [reload override buffer](#) to *source*.

When it comes time to [set the document's address](#) in the [navigation algorithm](#), use *address* as the [override URL](#).

3.1.1 The [Document](#) object

Spec bugs: 20302

The DOM specification defines a [Document](#) interface, which this specification extends significantly:

IDL

```
enum DocumentReadyState { "loading", "interactive", "complete" };

[OverrideBuiltins]
partial /*sealed*/ interface Document {
    // resource metadata management
    [PutForwards=href, Unforgeable] readonly attribute Location? location;
    attribute DOMString domain;
    readonly attribute DOMString referrer;
    attribute DOMString cookie;
    readonly attribute DOMString lastModified;
    readonly attribute DocumentReadyState readyState;

    // DOM tree accessors
    getter object (DOMString name);
    attribute DOMString title;
```

```

attribute DOMString dir;
attribute HTMLElement? body;
readonly attribute HTMLHeadElement? head;
[SameObject] readonly attribute HTMLCollection images;
[SameObject] readonly attribute HTMLCollection embeds;
[SameObject] readonly attribute HTMLCollection plugins;
[SameObject] readonly attribute HTMLCollection links;
[SameObject] readonly attribute HTMLCollection forms;
[SameObject] readonly attribute HTMLCollection scripts;
NodeList getElementsByName(DOMString elementName);
NodeList getItems(optional DOMString typeNames = ""); // microdata
[SameObject] readonly attribute DOMElementMap cssElementMap;
readonly attribute HTMLScriptElement? currentScript;

// dynamic markup insertion
Document open(optional DOMString type = "text/html", optional DOMString replace = "");
WindowProxy open(DOMString url, DOMString name, DOMString features, optional boolean replace = false);
void close();
void write(DOMString... text);
void writeln(DOMString... text);

// user interaction
readonly attribute WindowProxy? defaultView;
readonly attribute Element? activeElement;
boolean hasFocus();
attribute DOMString designMode;
boolean execCommand(DOMString commandId, optional boolean showUI = false, optional DOMString value = "");
boolean queryCommandEnabled(DOMString commandId);
boolean queryCommandIndeterm(DOMString commandId);
boolean queryCommandState(DOMString commandId);
boolean queryCommandSupported(DOMString commandId);
DOMString queryCommandValue(DOMString commandId);
readonly attribute HTMLCollection commands;

// special event handler IDL attributes that only apply to Document objects
[LenientThis] attribute EventHandler onreadystatechange;

// also has obsolete members
};

Document implements GlobalEventHandlers;

```

3.1.2 Resource metadata management

Note

document.referrer^{p103}

Returns the address of the Document^{p102} from which the user navigated to this one, unless it was blocked or there was no such document, in which case it returns the empty string.

The noreferrer^{p255} link type can be used to block the referrer.

The referrer attribute must return the document's referrer^{p102}.

Note In the case of HTTP, the referrer^{p103} IDL attribute will match the Referer^{p49} (sic) header that was sent when fetching^{p84} the current page.

Note Typically user agents are configured to not report referrers in the case where the referrer uses an encrypted protocol and the current page does not (e.g. when navigating from an [https:](#) page to an [http:](#) page).

Note

document.cookie^{p104} [= value]

Returns the HTTP cookies that apply to the [Document^{p102}](#). If there are no cookies or cookies can't be applied to this resource, the empty string will be returned.

Can be set, to add a new cookie to the element's set of HTTP cookies.

If the contents are [sandboxed into a unique origin^{p780}](#) (e.g. in an [iframe^{p299}](#) with the [sandbox^{p303}](#) attribute), a [SecurityError^{p50}](#) exception will be thrown on getting and setting.

The [cookie](#) attribute represents the cookies of the resource identified by [the document's address](#).

A [Document^{p102}](#) object that falls into one of the following conditions is a **cookie-averse Document object**:

- A [Document^{p102}](#) that has no [browsing context^{b762}](#).
- A [Document^{p102}](#) whose [address](#) does not use a server-based naming authority.

On getting, if the document is a [cookie-averse Document object^{p104}](#), then the user agent must return the empty string. Otherwise, if the [Document^{p102}](#)'s [origin^{p776}](#) is not a scheme/host/port tuple, the user agent must throw a [SecurityError^{p50}](#) exception. Otherwise, the user agent must first [obtain the storage mutex^{p838}](#) and then return the [cookie-string^{p49}](#) for [the document's address](#) for a "non-HTTP" API, decoded using the [UTF-8 decoder^{p47}](#). [COOKIES]^{p1148} Spec bugs: 27817

On setting, if the document is a [cookie-averse Document object^{p104}](#), then the user agent must do nothing. Otherwise, if the [Document^{p102}](#)'s [origin^{p776}](#) is not a scheme/host/port tuple, the user agent must throw a [SecurityError^{p50}](#) exception. Otherwise, the user agent must [obtain the storage mutex^{p838}](#) and then act as it would when [receiving a set-cookie-string^{p49}](#) for [the document's address](#) via a "non-HTTP" API, consisting of the new value encoded as UTF-8. [COOKIES]^{p1148} [ENCODING]^{p1150}

Note Since the [cookie^{p104}](#) attribute is accessible across frames, the path restrictions on cookies are only a tool to help manage which cookies are sent to which parts of the site, and are not in any way a security feature.

Note

document.lastModified^{b104}

Returns the date of the last modification to the document, as reported by the server, in the form "MM/DD/YYYY hh:mm:ss", in the user's local time zone.

If the last modification date is not known, the current time is returned instead.

The [lastModified](#) attribute, on getting, must return the date and time of the [Document^{p102}](#)'s source file's last modification, in the user's local time zone, in the following format:

1. The month component of the date.
2. A U+002F SOLIDUS character (/).
3. The day component of the date.
4. A U+002F SOLIDUS character (/).
5. The year component of the date.
6. A U+0020 SPACE character.
7. The hours component of the time.
8. A U+003A COLON character (:).
9. The minutes component of the time.

10. A U+003A COLON character (:).

11. The seconds component of the time.

All the numeric components above, other than the year, must be given as two [ASCII digits](#)^{p58} representing the number in base ten, zero-padded if necessary. The year must be given as the shortest possible string of four or more [ASCII digits](#)^{p58} representing the number in base ten, zero-padded if necessary.

The [Document](#)^{p102}'s source file's last modification date and time must be derived from relevant features of the networking protocols used, e.g. from the value of the HTTP [Last-Modified](#)^{p49} header of the document, or from metadata in the file system for local files. If the last modification date and time are not known, the attribute must return the current date and time in the above format.

Note

`document.readyState`^{p105}

Returns "loading" while the [Document](#)^{p102} is loading, "interactive" once it is finished parsing but still loading sub-resources, and "complete" once it has loaded.

The [readystatechange](#)^{p1144} event fires on the [Document](#)^{p102} object when this value changes.

Each document has a **current document readiness**. When a [Document](#)^{p102} object is created, it must have its [current document readiness](#)^{p105} set to the string "loading" if the document is associated with an [HTML parser](#)^{p952}, an [XML parser](#)^{p1054}, or an XSLT processor, and to the string "complete" otherwise. Various algorithms during page loading affect this value. When the value is set, the user agent must [fire a simple event](#)^{p846} named [readystatechange](#)^{p1144} at the [Document](#)^{p102} object.

A [Document](#)^{p102} is said to have an **active parser** if it is associated with an [HTML parser](#)^{p952} or an [XML parser](#)^{p1054} that has not yet been [stopped](#)^{p1033} or [aborted](#)^{p1033}.

The [readyState](#) IDL attribute must, on getting, return the [current document readiness](#)^{p105}.

3.1.3 DOM tree accessors

The [html](#) element of a document is the document's root element, if there is one and it's an [html](#)^{p137} element, or null otherwise.

Note

`document.head`^{p105}

Returns [the head element](#)^{p105}.

The [head](#) element of a document is the first [head](#)^{p138} element that is a child of [the html element](#)^{p105}, if there is one, or null otherwise.

The [head](#) attribute, on getting, must return [the head element](#)^{p105} of the document (a [head](#)^{p138} element or null).

Note

`document.title`^{p105} [= value]

Returns the document's title, as given by [the title element](#)^{p105} for HTML and as given by the SVG [title](#) element for SVG.

Can be set, to update the document's title. If there is no appropriate element to update, the new value is ignored.

The [title](#) element of a document is the first [title](#)^{p139} element in the document (in [tree order](#)^{p42}), if there is one, or null otherwise.

The [title](#) attribute must, on getting, run the following algorithm:

1. If the [root element](#)^{p42} is an [svg](#)^{p396} element in the [SVG namespace](#)^{p101}, then let *value* be a concatenation of the data of all the child [Text](#)^{p51} nodes of the first [title](#) element in the [SVG namespace](#)^{p101} that is a child of the [root element](#)^{p42}. [SVG]^{p1153}

2. Otherwise, let *value* be a concatenation of the data of all the child [Text](#)^{p51} nodes of [the title element](#)^{p105}, in [tree order](#)^{p42}, or the empty string if [the title element](#)^{p105} is null.
3. [Strip and collapse whitespace](#)^{p59} in *value*.
4. Return *value*.

On setting, the steps corresponding to the first matching condition in the following list must be run:

- ↪ If the [root element](#)^{p42} is an [svg](#)^{p396} element in the [SVG namespace](#)^{p101} [[SVG](#)]^{p1153}
 1. Let *element* be the first [title](#) element in the [SVG namespace](#)^{p101} that is a child of the [root element](#)^{p42}, if any. If there isn't one, create a [title](#) element in the [SVG namespace](#)^{p101}, append it to the [root element](#)^{p42}, and let *element* be that element. [[SVG](#)]^{p1153}
 2. Act as if the [textContent](#)^{p51} IDL attribute of *element* was set to the new value being assigned.
- ↪ If the [root element](#)^{p42} is in the [HTML namespace](#)^{p101}
 1. If [the title element](#)^{p105} is null and [the head element](#)^{p105} is null, then abort these steps.
 2. If [the title element](#)^{p105} is null, then create a new [title](#)^{p139} element and [append](#)^{p51} it to [the head element](#)^{p105}, and let *element* be the newly created element; otherwise, let *element* be [the title element](#)^{p105}.
 3. Act as if the [textContent](#)^{p51} IDL attribute of *element* was set to the new value being assigned.
- ↪ Otherwise

Do nothing.

Note `document.body`^{p106} [= *value*]

Returns [the body element](#)^{p106}.

Can be set, to replace [the body element](#)^{p106}.

If the new value is not a [body](#)^{p157} or [frameset](#)^{p1104} element, this will throw a [HierarchyRequestError](#)^{p50} exception.

The **body element** of a document is the first child of [the html element](#)^{p105} that is either a [body](#)^{p157} element or a [frameset](#)^{p1104} element. If there is no such element, it is null.

The **body** attribute, on getting, must return [the body element](#)^{p106} of the document (either a [body](#)^{p157} element, a [frameset](#)^{p1104} element, or null). On setting, the following algorithm must be run:

1. If the new value is not a [body](#)^{p157} or [frameset](#)^{p1104} element, then throw a [HierarchyRequestError](#)^{p50} exception and abort these steps.
2. Otherwise, if the new value is the same as [the body element](#)^{p106}, do nothing. Abort these steps.
3. Otherwise, if [the body element](#)^{p106} is not null, then replace that element with the new value in the DOM, as if the root element's [replaceChild\(\)](#) method had been called with the new value and [the incumbent body element](#)^{p106} as its two arguments respectively, then abort these steps.
4. Otherwise, if there is no root element, throw a [HierarchyRequestError](#)^{p50} exception and abort these steps.
5. Otherwise, [the body element](#)^{p106} is null, but there's a root element. Append the new value to the root element.

Note `document.images`^{p107}

Returns an [HTMLCollection](#)^{p51} of the [img](#)^{p272} elements in the [Document](#)^{p102}.

`document.embedsp107`
`document.pluginsp107`

Return an [HTMLCollection^{p51}](#) of the [embed^{p307}](#) elements in the [Document^{p102}](#).

`document.linksp107`

Returns an [HTMLCollection^{p51}](#) of the [a^{p208}](#) and [area^{p390}](#) elements in the [Document^{p102}](#) that have [href^{p245}](#) attributes.

`document.formsp107`

Return an [HTMLCollection^{p51}](#) of the [form^{p447}](#) elements in the [Document^{p102}](#).

`document.scriptsp107`

Return an [HTMLCollection^{p51}](#) of the [script^{p591}](#) elements in the [Document^{p102}](#).

The [images](#) attribute must return an [HTMLCollection^{p51}](#) rooted at the [Document^{p102}](#) node, whose filter matches only [img^{p272}](#) elements.

The [embeds](#) attribute must return an [HTMLCollection^{p51}](#) rooted at the [Document^{p102}](#) node, whose filter matches only [embed^{p307}](#) elements.

The [plugins](#) attribute must return the same object as that returned by the [embeds^{p107}](#) attribute.

The [links](#) attribute must return an [HTMLCollection^{p51}](#) rooted at the [Document^{p102}](#) node, whose filter matches only [a^{p208}](#) elements with [href^{p245}](#) attributes and [area^{p390}](#) elements with [href^{p245}](#) attributes.

The [forms](#) attribute must return an [HTMLCollection^{p51}](#) rooted at the [Document^{p102}](#) node, whose filter matches only [form^{p447}](#) elements.

The [scripts](#) attribute must return an [HTMLCollection^{p51}](#) rooted at the [Document^{p102}](#) node, whose filter matches only [script^{p591}](#) elements.

Note

`collection = document.getElementsByNamep107(name)`

Returns a [NodeList^{p51}](#) of elements in the [Document^{p102}](#) that have a `name` attribute with the value `name`.

The [getElementsByName \(name\)](#) method takes a string `name`, and must return a [live^{p43}](#) [NodeList^{p51}](#) containing all the [HTML elements^{p42}](#) in that document that have a `name` attribute whose value is equal to the `name` argument (in a [case-sensitive^{p58}](#) manner), in [tree order^{p42}](#). When the method is invoked on a [Document^{p102}](#) object again with the same argument, the user agent may return the same as the object returned by the earlier call. In other cases, a new [NodeList^{p51}](#) object must be returned.

Note

`element.cssElementMapp107`

Returns a [DOMElementMap^{p97}](#) object for the [Document^{p102}](#) representing the current [CSS element reference identifiers^{p53}](#).

The [cssElementMap](#) IDL attribute allows authors to define [CSS element reference identifiers^{p53}](#), which are used in certain CSS features to override the normal [ID^{p51}](#)-based mapping. [\[CSSIMAGES\]^{p1149}](#)

When a [Document^{p102}](#) is created, it must be associated with an initially-empty **CSS ID overrides list**, which consists of a list of mappings each of which consists of a string name mapped to an [Element^{p51}](#) node.

Each entry in the [CSS ID overrides list^{p107}](#), while it is in the list and is either [in the Document^{p42}](#) or is an [img^{p272}](#), [video^{p317}](#), or [canvas^{p607}](#) element, defines a [CSS element reference identifier^{p53}](#) mapping the given name to the given [Element^{p51}](#). [\[CSSIMAGES\]^{p1149}](#)

On getting, the [cssElementMap^{p107}](#) IDL attribute must return a [DOMElementMap^{p97}](#) object, associated with the following algorithms, which expose the current mappings:

The algorithm for getting the list of name-element mappings

Return the [Document^{p102}](#)'s [CSS ID overrides list^{p107}](#), maintaining the order in which the entries were originally added to the list.

The algorithm for mapping a name to a certain element

Let *name* be the name passed to the algorithm and *element* be the [Element^{p51}](#) passed to the algorithm.

If *element* is null, run the algorithm for deleting mappings by name, passing it *name*.

Otherwise, if there is an entry in the [Document^{p102}](#)'s [CSS ID overrides list^{p107}](#) whose name is *name*, replace its current value with *element*.

Otherwise, add a mapping to the [Document^{p102}](#)'s [CSS ID overrides list^{p107}](#) whose name is *name* and whose element is *element*.

The algorithm for deleting mappings by name

If there is an entry in the [Document^{p102}](#)'s [CSS ID overrides list^{p107}](#) whose name is the name passed to this algorithm, remove it. This also undefines the [CSS element reference identifier^{p53}](#) for that name. [\[CSSIMAGES\]^{p1149}](#)

Note

`document.currentScriptp108`

Returns the [script^{p591}](#) element that is currently executing. In the case of reentrant [script^{p591}](#) execution, returns the one that most recently started executing amongst those that have not yet finished executing.

Returns null if the [Document^{p102}](#) is not currently executing a [script^{p591}](#) element (e.g. because the running script is an event handler, or a timeout).

The [currentScript](#) attribute, on getting, must return the value to which it was most recently initialised. When the [Document^{p102}](#) is created, the [currentScript^{p108}](#) must be initialised to null.

The [Document^{p102}](#) interface [supports named properties^{p49}](#). The [supported property names^{p49}](#) at any moment consist of the values of the [name](#) content attributes of all the [applet^{p1101}](#), [exposed^{p108}](#) [embed^{p307}](#), [form^{p447}](#), [iframe^{p299}](#), [img^{p272}](#), and [exposed^{p108}](#) [object^{p310}](#) elements in the [Document^{p102}](#) that have non-empty [name](#) content attributes, and the values of the [id^{p122}](#) content attributes of all the [applet^{p1101}](#) and [exposed^{p108}](#) [object^{p310}](#) elements in the [Document^{p102}](#) that have non-empty [id^{p122}](#) content attributes, and the values of the [id^{p122}](#) content attributes of all the [img^{p272}](#) elements in the [Document^{p102}](#) that have both non-empty [name](#) content attributes and non-empty [id^{p122}](#) content attributes. The [supported property names^{p49}](#) must be in [tree order^{p42}](#), ignoring later duplicates, with values from [id^{p122}](#) attributes coming before values from [name](#) attributes when the same element contributes both.

To [determine the value of a named property^{p49}](#) *name* when the [Document](#) object is indexed for property retrieval, the user agent must return the value obtained using the following steps:

1. Let *elements* be the list of [named elements^{p108}](#) with the name *name* in the [Document^{p102}](#).

Note There will be at least one such element, by definition.

2. If *elements* has only one element, and that element is an [iframe^{p299}](#) element, then return the [WindowProxy^{p775}](#) object of the [nested browsing context^{p763}](#) represented by that [iframe^{p299}](#) element, and abort these steps.
3. Otherwise, if *elements* has only one element, return that element and abort these steps.
4. Otherwise return an [HTMLCollection^{p51}](#) rooted at the [Document^{p102}](#) node, whose filter matches only [named elements^{p108}](#) with the name *name*.

Named elements with the name *name*, for the purposes of the above algorithm, are those that are either:

- [applet^{p1101}](#), [exposed^{p108}](#) [embed^{p307}](#), [form^{p447}](#), [iframe^{p299}](#), [img^{p272}](#), or [exposed^{p108}](#) [object^{p310}](#) elements that have a [name](#) content attribute whose value is *name*, or
- [applet^{p1101}](#) or [exposed^{p108}](#) [object^{p310}](#) elements that have an [id^{p122}](#) content attribute whose value is *name*, or
- [img^{p272}](#) elements that have an [id^{p122}](#) content attribute whose value is *name*, and that have a non-empty [name](#) content attribute present also.

An [embed^{p307}](#) or [object^{p310}](#) element is said to be **exposed** if it has no [exposed^{p108}](#) [object^{p310}](#) ancestor, and, for [object^{p310}](#) elements, is additionally either not showing its [fallback content^{p116}](#) or has no [object^{p310}](#) or [embed^{p307}](#) descendants.

Note The `dir`^{p127} attribute on the `Document`^{p102} interface is defined along with the `dir`^{p125} content attribute.

3.1.4 Loading XML documents

IDL

```
partial interface XMLHttpRequest {
  boolean load(DOMString url);
};
```

The `load(url)` method must run the following steps:

1. Let `document` be the `XMLDocument`^{p51} object on which the method was invoked.
2. Resolve^{p82} the method's first argument, relative to the API base URL^{p829} specified by the entry settings object^{p831}. If this is not successful, throw a `SyntaxError`^{p50} exception and abort these steps. Otherwise, let `url` be the resulting absolute URL^{p48}.
3. If the `origin`^{p776} of `url` is not the same as the `origin`^{p776} of `document`, throw a `SecurityError`^{p50} exception and abort these steps.
4. Remove all child nodes of `document`, without firing any mutation events.
5. Set the current document readiness^{p105} of `document` to "loading".
6. Run the remainder of these steps in parallel^{p41}, and return true from the method.
7. Let `result` be a `Document`^{p102} object.
8. Let `success` be false.
9. Fetch^{p84} `url` from the `origin`^{p776} of `document`, using the referrer source^{p829} specified by the entry settings object^{p831}, with the blocking flag set and the force same-origin flag set.
10. If the fetch attempt was successful, and the resource's Content-Type metadata^{p86} is an XML MIME type^{p42}, then run these substeps:
 1. Create a new `XML_parser`^{p1054} associated with the `result` document.
 2. Pass this parser the fetched document.
 3. If there is an XML well-formedness or XML namespace well-formedness error, then remove all child nodes from `result`. Otherwise let `success` be true.
11. Queue a task^{p835} to run the following steps.
 1. Set the current document readiness^{p105} of `document` to "complete".
 2. Replace all the children of `document` by the children of `result` (even if it has no children), firing mutation events as if a `DocumentFragment`^{p51} containing the new children had been inserted.
 3. Fire a simple event^{p846} named `load`^{p1144} at `document`.

3.2 Elements

Spec bugs: 25325

3.2.1 Semantics

Spec bugs: 28078

Elements, attributes, and attribute values in HTML are defined (by this specification) to have certain meanings (semantics). For example, the `ol`^{p195} element represents an ordered list, and the `lang`^{p123} attribute represents the language of the content.

These definitions allow HTML processors, such as Web browsers or search engines, to present and use documents and applications in a wide variety of contexts that the author might not have considered.

Example

As a simple example, consider a Web page written by an author who only considered desktop computer Web browsers:

```

<!DOCTYPE HTML>
<html>
  <head>
    <title>My Page</title>
  </head>
  <body>
    <h1>Welcome to my page</h1>
    <p>I like cars and lorries and have a big Jeep!</p>
    <h2>Where I live</h2>
    <p>I live in a small hut on a mountain!</p>
  </body>
</html>

```

Because HTML conveys *meaning*, rather than presentation, the same page can also be used by a small browser on a mobile phone, without any change to the page. Instead of headings being in large letters as on the desktop, for example, the browser on the mobile phone might use the same size text for the whole the page, but with the headings in bold.

But it goes further than just differences in screen size: the same page could equally be used by a blind user using a browser based around speech synthesis, which instead of displaying the page on a screen, reads the page to the user, e.g. using headphones. Instead of large text for the headings, the speech browser might use a different volume or a slower voice.

That's not all, either. Since the browsers know which parts of the page are the headings, they can create a document outline that the user can use to quickly navigate around the document, using keys for "jump to next heading" or "jump to previous heading". Such features are especially common with speech browsers, where users would otherwise find quickly navigating a page quite difficult.

Even beyond browsers, software can make use of this information. Search engines can use the headings to more effectively index a page, or to provide quick links to subsections of the page from their results. Tools can use the headings to create a table of contents (that is in fact how this very specification's table of contents is generated).

This example has focused on headings, but the same principle applies to all of the semantics in HTML.

Authors must not use elements, attributes, or attribute values for purposes other than their appropriate intended semantic purpose, as doing so prevents software from correctly processing the page.

Example

For example, the following snippet, intended to represent the heading of a corporate site, is non-conforming because the second line is not intended to be a heading of a subsection, but merely a subheading or subtitle (a subordinate heading for the same section).

```

<body>
  <h1>ACME Corporation</h1>
  <h2>The leaders in arbitrary fast delivery since 1920</h2>
  ...

```

The hgroup^{p170} element is intended for these kinds of situations:

```

<body>
  <hgroup>
    <h1>ACME Corporation</h1>
    <h2>The leaders in arbitrary fast delivery since 1920</h2>
  </hgroup>
  ...

```

Example

The document in this next example is similarly non-conforming, despite being syntactically correct, because the data placed in the cells is clearly not tabular data, and the cite^{p214} element mis-used:

```

<!DOCTYPE HTML>
<html lang="en-GB">
  <head> <title> Demonstration </title> </head>
  <body>
    <table>
      <tr> <td> My favourite animal is the cat. </td> </tr>
      <tr>

```

```

<td>
  <a href="http://example.org/~ernest/"><cite>Ernest</cite></a>,
  in an essay from 1992
</td>
</tr>
</table>
</body>
</html>

```

This would make software that relies on these semantics fail: for example, a speech browser that allowed a blind user to navigate tables in the document would report the quote above as a table, confusing the user; similarly, a tool that extracted titles of works from pages would extract "Ernest" as the title of a work, even though it's actually a person's name, not a title.

A corrected version of this document might be:

```

<!DOCTYPE HTML>
<html lang="en-GB">
  <head> <title> Demonstration </title> </head>
  <body>
    <blockquote>
      <p> My favourite animal is the cat. </p>
    </blockquote>
    <p>
      <a href="http://example.org/~ernest/">Ernest</a>,
      in an essay from 1992
    </p>
  </body>
</html>

```

Authors must not use elements, attributes, or attribute values that are not permitted by this specification or [other applicable specifications^{p56}](#), as doing so makes it significantly harder for the language to be extended in the future.

Example

In the next example, there is a non-conforming attribute value ("carpet") and a non-conforming attribute ("texture"), which is not permitted by this specification:

```
<label>Carpet: <input type="carpet" name="c" texture="deep pile"></label>
```

Here would be an alternative and correct way to mark this up:

```
<label>Carpet: <input type="text" class="carpet" name="c" data-texture="deep pile"></label>
```

Through scripting and using other mechanisms, the values of attributes, text, and indeed the entire structure of the document may change dynamically while a user agent is processing it. The semantics of a document at an instant in time are those represented by the state of the document at that instant in time, and the semantics of a document can therefore change over time. User agents must update their presentation of the document as this occurs.

Example

HTML has a [progress^{p518}](#) element that describes a progress bar. If its "value" attribute is dynamically updated by a script, the UA would update the rendering to show the progress changing.

Spec bugs: [27877](#)

3.2.2 Elements in the DOM

The nodes representing [HTML elements^{p42}](#) in the DOM must implement, and expose to scripts, the interfaces listed for them in the relevant sections of this specification. This includes [HTML elements^{p42}](#) in [XML documents^{p51}](#), even when those documents are in another context (e.g. inside an XSLT transform).

Elements in the DOM **represent** things; that is, they have intrinsic *meaning*, also known as semantics.

Example

For example, an [ol^{p195}](#) element represents an ordered list.

The basic interface, from which all the [HTML elements](#)^{p42}, interfaces inherit, and which must be used by elements that have no additional requirements, is the [HTMLElement](#)^{p112} interface.

IDL

```
interface HTMLElement : Element {
    // metadata attributes
    attribute DOMString title;
    attribute DOMString lang;
    attribute boolean translate;
    attribute DOMString dir;
    [SameObject] readonly attribute DOMStringMap dataset;

    // microdata
    attribute boolean itemScope;
    [PutForwards=value] readonly attribute DOMSettableTokenList itemType;
    attribute DOMString itemId;
    [PutForwards=value] readonly attribute DOMSettableTokenList itemRef;
    [PutForwards=value] readonly attribute DOMSettableTokenList itemProp;
    readonly attribute HTMLPropertiesCollection properties;
    attribute any itemValue; // acts as DOMString on setting

    // user interaction
    attribute boolean hidden;
    void click();
    attribute long tabIndex;
    void focus();
    void blur();
    attribute DOMString accessKey;
    readonly attribute DOMString accessKeyLabel;
    attribute boolean draggable;
    [PutForwards=value] readonly attribute DOMSettableTokenList dropzone;
    attribute HTMLMenuElement? contextMenu;
    attribute boolean spellcheck;
    void forceSpellCheck();

    // command API
    readonly attribute DOMString? commandType;
    readonly attribute DOMString? commandLabel;
    readonly attribute DOMString? commandIcon;
    readonly attribute boolean? commandHidden;
    readonly attribute boolean? commandDisabled;
    readonly attribute boolean? commandChecked;
};

HTMLElement implements GlobalEventHandlers;
HTMLElement implements ElementContentEditable;

interface HTMLUnknownElement : HTMLElement { };
```

The [HTMLElement](#)^{p112} interface holds methods and attributes related to a number of disparate features, and the members of this interface are therefore described in various different sections of this specification.

The [HTMLUnknownElement](#)^{p112} interface must be used for [HTML elements](#)^{p42} that are not defined by this specification (or [other applicable specifications](#)^{p56}).

3.2.3 Element definitions

Each element in this specification has a definition that includes the following information:

Categories

A list of [categories](#)^{p114} to which the element belongs. These are used when defining the [content models](#)^{p113} for each element.

Contexts in which this element can be used

A non-normative description of where the element can be used. This information is redundant with the content models of elements that allow this one as a child, and is provided only as a convenience.

Note *For simplicity, only the most specific expectations are listed. For example, an element that is both [flow content](#)^{p115} and [phrasing content](#)^{p116} can be used anywhere that either [flow content](#)^{p115} or [phrasing content](#)^{p116} is expected, but since anywhere that [flow content](#)^{p115} is expected, [phrasing content](#)^{p116} is also expected (since all [phrasing content](#)^{p116} is [flow content](#)^{p115}), only "where [phrasing content](#)^{p116} is expected" will be listed.*

Content model

A normative description of what content must be included as children and descendants of the element.

Tag omission in text/html

A non-normative description of whether, in the [text/html](#)^{p116} syntax, the [start](#)^{p944} and [end](#)^{p944} tags can be omitted. This information is redundant with the normative requirements given in the [optional tags](#)^{p946} section, and is provided in the element definitions only as a convenience.

Content attributes

A normative list of attributes that may be specified on the element (except where otherwise disallowed), along with non-normative descriptions of those attributes. (The content to the left of the dash is normative, the content to the right of the dash is not.)

DOM interface

A normative definition of a DOM interface that such elements must implement.

This is then followed by a description of what the element [represents](#)^{p111}, along with any additional normative conformance criteria that may apply to authors and implementations. Examples are sometimes also included.

3.2.3.1 Attributes

Except where otherwise specified, attributes on [HTML elements](#)^{p42} may have any string value, including the empty string. Except where explicitly stated, there is no restriction on what text can be specified in such attributes.

Spec bugs: [28139](#) :

3.2.4 Content models

Each element defined in this specification has a content model: a description of the element's expected [contents](#)^{p113}. An [HTML element](#)^{p42} must have contents that match the requirements described in the element's content model. The [contents](#) of an element are its children in the DOM, except for [template](#)^{p604} elements, where the children are those in the [template contents](#)^{p605} (a separate [DocumentFragment](#)^{p51} assigned to the element when the element is created).

The [space characters](#)^{p58} are always allowed between elements. User agents represent these characters between elements in the source markup as [Text](#)^{p51} nodes in the DOM. Empty [Text](#)^{p51} nodes and [Text](#)^{p51} nodes consisting of just sequences of those characters are considered [inter-element whitespace](#).

[Inter-element whitespace](#)^{p113}, comment nodes, and processing instruction nodes must be ignored when establishing whether an element's contents match the element's content model or not, and must be ignored when following algorithms that define document and element semantics.

Note *Thus, an element A is said to be preceded or followed by a second element B if A and B have the same parent node and there are no other element nodes or [Text](#)^{p51} nodes (other than [inter-element whitespace](#)^{p113}) between them. Similarly, a node is the only child of an element if that element contains no other nodes other than [inter-element whitespace](#)^{p113}, comment nodes, and processing instruction nodes.*

Authors must not use [HTML elements](#)^{p42} anywhere except where they are explicitly allowed, as defined for each element, or as explicitly required by other specifications. For XML compound documents, these contexts could be inside elements from other namespaces, if those elements are defined as providing the relevant contexts.

Example

For example, the Atom specification defines a `content` element. When its `type` attribute has the value `xhtml`, the Atom specification requires that it contain a single HTML `div`^{p207} element. Thus, a `div`^{p207} element is allowed in that context, even though this is not explicitly normatively stated by this specification. [ATOM]^{p1148}

In addition, [HTML elements](#)^{p42} may be orphan nodes (i.e. without a parent node).

Example

For example, creating a `td`^{p412} element and storing it in a global variable in a script is conforming, even though `td`^{p412} elements are otherwise only supposed to be used inside `tr`^{p411} elements.

```
var data = {
    name: "Banana",
    cell: document.createElement('td'),
};
```

3.2.4.1 The "nothing" content model

When an element's content model is **nothing**, the element must contain no `Text`^{p51} nodes (other than [inter-element whitespace](#)^{p113}) and no element nodes.

Note Most HTML elements whose content model is "nothing" are also, for convenience, [void elements](#)^{p942} (elements that have no [end tag](#)^{p944} in the [HTML syntax](#)^{p941}). However, these are entirely separate concepts.

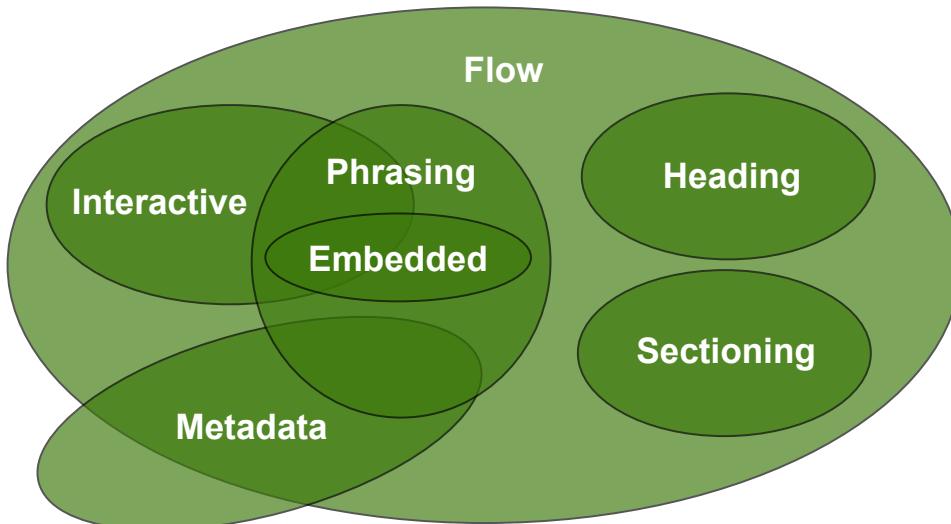

3.2.4.2 Kinds of content

Each element in HTML falls into zero or more **categories** that group elements with similar characteristics together. The following broad categories are used in this specification:

- [Metadata content](#)^{p115}
- [Flow content](#)^{p115}
- [Sectioning content](#)^{p116}
- [Heading content](#)^{p116}
- [Phrasing content](#)^{p116}
- [Embedded content](#)^{p116}
- [Interactive content](#)^{p116}

Note Some elements also fall into other categories, which are defined in other parts of this specification.

These categories are related as follows:

Sectioning content, heading content, phrasing content, embedded content, and interactive content are all types of flow content. Metadata is sometimes flow content. Metadata and interactive content are sometimes phrasing content. Embedded content is also a type of phrasing content, and sometimes is interactive content.

Other categories are also used for specific purposes, e.g. form controls are specified using a number of categories to define common requirements. Some elements have unique requirements and do not fit into any particular category.

3.2.4.2.1 Metadata content

Metadata content is content that sets up the presentation or behaviour of the rest of the content, or that sets up the relationship of the document with other documents, or that conveys other "out of band" information.

⇒ [base^{p140}](#), [link^{p141}](#), [meta^{p145}](#), [noscript^{p602}](#), [script^{p591}](#), [style^{p154}](#), [template^{p604}](#), [title^{p139}](#)

Elements from other namespaces whose semantics are primarily metadata-related (e.g. RDF) are also [metadata content^{p115}](#).

Example

Thus, in the XML serialisation, one can use RDF, like this:

```
<html xmlns="http://www.w3.org/1999/xhtml"
      xmlns:r="http://www.w3.org/1999/02/22-rdf-syntax-ns#>
<head>
  <title>Hederal's Home Page</title>
  <r:RDF>
    <Person xmlns="http://www.w3.org/2000/10/swap/pim/contact#"
            r:about="http://hederal.example.com/#">
      <fullName>Cat Hederal</fullName>
      <mailbox r:resource="mailto:hederal@damowmow.com"/>
      <personalTitle>Sir</personalTitle>
    </Person>
  </r:RDF>
</head>
<body>
  <h1>My home page</h1>
  <p>I like playing with string, I guess. Sister says squirrels are fun
  too so sometimes I follow her to play with them.</p>
</body>
</html>
```

This isn't possible in the HTML serialisation, however.

3.2.4.2.2 Flow content

Most elements that are used in the body of documents and applications are categorised as **flow content**.

⇒ [a^{p208}](#), [abbr^{p218}](#), [address^{p175}](#), [area^{p390}](#) (if it is a descendant of a [map^{p389}](#) element), [article^{p159}](#), [aside^{p166}](#), [audio^{p321}](#), [b^{p236}](#), [bdi^{p240}](#), [bdo^{p241}](#), [blockquote^{p193}](#), [br^{p242}](#), [button^{p495}](#), [canvas^{p607}](#), [cite^{p214}](#), [code^{p231}](#), [data^{p226}](#), [datalist^{p503}](#), [del^{p262}](#), [details^{p567}](#), [dfn^{p217}](#), [dialog^{p586}](#), [div^{p207}](#), [dl^{p199}](#), [em^{p210}](#), [embed^{p307}](#), [fieldset^{p524}](#), [figure^{p202}](#), [footer^{p173}](#), [form^{p447}](#), [h1^{p168}](#), [h2^{p168}](#), [h3^{p168}](#), [h4^{p168}](#), [h5^{p168}](#), [h6^{p168}](#), [header^{p171}](#), [hgroup^{p170}](#), [hr^{p190}](#), [i^{p235}](#), [iframe^{p299}](#), [img^{p272}](#), [input^{p452}](#), [ins^{p260}](#), [kbd^{p234}](#), [keygen^{p513}](#), [label^{p451}](#), [link^{p141}](#) (if the [itemprop^{p692}](#) attribute is present), [main^{p205}](#), [map^{p389}](#), [mark^{p238}](#), [math^{p395}](#), [menu^{p571}](#), [meta^{p145}](#) (if the [itemprop^{p692}](#) attribute is present), [meter^{p519}](#), [nav^{p163}](#), [noscript^{p602}](#), [object^{p310}](#), [ol^{p195}](#), [output^{p516}](#), [p^{p187}](#), [pre^{p191}](#), [progress^{p518}](#), [q^{p215}](#), [ruby^{p219}](#), [s^{p214}](#), [samp^{p233}](#), [script^{p591}](#), [section^{p161}](#), [select^{p498}](#), [small^{p212}](#), [span^{p242}](#), [strong^{p211}](#), [style^{p154}](#) (if the [scoped^{p154}](#) attribute is present), [sub^{p235}](#), [sup^{p235}](#), [svg^{p396}](#), [table^{p398}](#), [template^{p604}](#), [textarea^{p508}](#), [time^{p227}](#), [u^{p237}](#), [ul^{p197}](#), [var^{p232}](#), [video^{p317}](#), [wbr^{p243}](#), [text^{p116}](#)

3.2.4.2.3 Sectioning content

Sectioning content is content that defines the scope of [headings^{p116}](#) and [footers^{p173}](#).

⇒ [article^{p159}](#), [aside^{p166}](#), [nav^{p163}](#), [section^{p161}](#)

Each [sectioning content^{p116}](#) element potentially has a heading and an [outline^{p178}](#). See the section on [headings and sections^{p176}](#) for further details.

Note *There are also certain elements that are [sectioning roots^{p176}](#). These are distinct from [sectioning content^{p116}](#), but they can also have an [outline^{p178}](#).*

3.2.4.2.4 Heading content

Heading content defines the header of a section (whether explicitly marked up using [sectioning content^{p116}](#) elements, or implied by the heading content itself).

⇒ [h1^{p168}](#), [h2^{p168}](#), [h3^{p168}](#), [h4^{p168}](#), [h5^{p168}](#), [h6^{p168}](#), [hgroup^{p170}](#)

3.2.4.2.5 Phrasing content

Spec bugs: [25493](#)

Phrasing content is the text of the document, as well as elements that mark up that text at the intra-paragraph level. Runs of [phrasing content^{p116}](#) form [paragraphs^{p118}](#).

⇒ [a^{p208}](#), [abbr^{p218}](#), [area^{p390}](#) (if it is a descendant of a [map^{p389}](#) element), [audio^{b321}](#), [b^{b236}](#), [bdi^{p240}](#), [bdo^{p241}](#), [br^{p242}](#), [button^{p495}](#), [canvas^{p607}](#), [cite^{p214}](#), [code^{p231}](#), [data^{p226}](#), [datalist^{p503}](#), [del^{b262}](#), [dfn^{p217}](#), [em^{p210}](#), [embed^{b307}](#), [i^{p235}](#), [iframe^{p299}](#), [img^{p272}](#), [input^{p452}](#), [ins^{p260}](#), [kbd^{p234}](#), [keygen^{p513}](#), [label^{p451}](#), [link^{p141}](#) (if the [itemprop^{p692}](#) attribute is present), [map^{b389}](#), [mark^{p238}](#), [math^{p395}](#), [meta^{p145}](#) (if the [itemprop^{p692}](#) attribute is present), [meter^{p519}](#), [noscript^{p602}](#), [object^{p310}](#), [output^{p516}](#), [progress^{p518}](#), [q^{p215}](#), [ruby^{p219}](#), [s^{p214}](#), [samp^{p233}](#), [script^{p591}](#), [select^{p498}](#), [small^{p212}](#), [span^{p242}](#), [strong^{p211}](#), [sub^{p235}](#), [sup^{p235}](#), [svg^{p396}](#), [template^{p604}](#), [textarea^{p508}](#), [time^{p227}](#), [u^{p237}](#), [var^{p232}](#), [video^{p317}](#), [wbr^{p243}](#), [text^{p116}](#)

Note *Most elements that are categorised as phrasing content can only contain elements that are themselves categorised as phrasing content, not any flow content.*

Text, in the context of content models, means either nothing, or [Text^{p51}](#) nodes. [Text^{p116}](#) is sometimes used as a content model on its own, but is also [phrasing content^{p116}](#), and can be [inter-element whitespace^{p113}](#) (if the [Text^{p51}](#) nodes are empty or contain just [space characters^{p51}](#)). Spec bugs: [23152](#)

[Text^{p51}](#) nodes and attribute values must consist of [Unicode characters^{p44}](#), must not contain U+0000 characters, must not contain permanently undefined Unicode characters (noncharacters), and must not contain [control characters^{p58}](#) other than [space characters^{p58}](#). This specification includes extra constraints on the exact value of [Text^{p51}](#) nodes and attribute values depending on their precise context.

3.2.4.2.6 Embedded content

Embedded content is content that imports another resource into the document, or content from another vocabulary that is inserted into the document.

⇒ [audio^{b321}](#), [canvas^{p607}](#), [embed^{p307}](#), [iframe^{p299}](#), [img^{p272}](#), [math^{p395}](#), [object^{p310}](#), [svg^{p396}](#), [video^{p317}](#)

Elements that are from namespaces other than the [HTML namespace^{p101}](#) and that convey content but not metadata, are [embedded content^{p116}](#) for the purposes of the content models defined in this specification. (For example, MathML, or SVG.)

Some embedded content elements can have **fallback content**: content that is to be used when the external resource cannot be used (e.g. because it is of an unsupported format). The element definitions state what the fallback is, if any.

3.2.4.2.7 Interactive content

Spec bugs: [15948](#)

Interactive content is content that is specifically intended for user interaction.

⇒ [a^{p208}](#), [audio^{p321}](#) (if the [controls^{p382}](#) attribute is present), [button^{p495}](#), [details^{p567}](#), [embed^{p307}](#), [iframe^{p299}](#), [img^{p272}](#) (if the [usemap^{p393}](#) attribute is present), [input^{p452}](#) (if the [type^{p454}](#) attribute is *not* in the [hidden^{p458}](#) state), [keygen^{p513}](#), [label^{p451}](#), [object^{p310}](#) (if the [usemap^{p393}](#) attribute is present), [select^{p498}](#), [textarea^{p508}](#), [sorting interface th elements^{p423}](#), [video^{p317}](#) (if the [controls^{p382}](#) attribute is present)

The [tabindex^{p729}](#) attribute can also make any element into [interactive content^{p116}](#).

Spec bugs: 18052

3.2.4.2.8 Palpable content

As a general rule, elements whose content model allows any [flow content^{p115}](#) or [phrasing content^{p116}](#) should have at least one node in its [contents^{p113}](#) that is **palpable content** and that does not have the [hidden^{p723}](#) attribute specified.

This requirement is not a hard requirement, however, as there are many cases where an element can be empty legitimately, for example when it is used as a placeholder which will later be filled in by a script, or when the element is part of a template and would on most pages be filled in but on some pages is not relevant.

Conformance checkers are encouraged to provide a mechanism for authors to find elements that fail to fulfill this requirement, as an authoring aid.

The following elements are palpable content:

⇒ [a^{p208}](#), [abbr^{p218}](#), [address^{p175}](#), [article^{p159}](#), [aside^{p166}](#), [audio^{p321}](#) (if the [controls^{p382}](#) attribute is present), [b^{p236}](#), [bdi^{p240}](#), [bdo^{p241}](#), [blockquote^{p193}](#), [button^{p495}](#), [canvas^{p607}](#), [cite^{p214}](#), [code^{p231}](#), [data^{p226}](#), [details^{p567}](#), [dfn^{p217}](#), [div^{p207}](#), [dl^{p199}](#) (if the element's children include at least one name-value group), [em^{p210}](#), [embed^{p307}](#), [fieldset^{p524}](#), [figure^{p202}](#), [footer^{p173}](#), [form^{p447}](#), [h1^{p168}](#), [h2^{p168}](#), [h3^{p168}](#), [h4^{p168}](#), [h5^{p168}](#), [h6^{p168}](#), [header^{p171}](#), [hgroup^{p170}](#), [i^{p235}](#), [iframe^{p299}](#), [img^{p272}](#), [input^{p452}](#) (if the [type^{p454}](#) attribute is *not* in the [hidden^{p458}](#) state), [ins^{p260}](#), [kbd^{p234}](#), [keygen^{p513}](#), [label^{p451}](#), [main^{p205}](#), [map^{p389}](#), [mark^{p238}](#), [math^{p395}](#), [menu^{p571}](#) (if the [type^{p572}](#) attribute is in the [toolbar^{p572}](#) state), [meter^{p519}](#), [nav^{p163}](#), [object^{p310}](#), [ol^{p195}](#) (if the element's children include at least one [li^{p198}](#) element), [output^{p516}](#), [p^{p187}](#), [pre^{p191}](#), [progress^{p518}](#), [q^{p215}](#), [ruby^{p219}](#), [s^{p214}](#), [samp^{p233}](#), [section^{p161}](#), [select^{p498}](#), [small^{p212}](#), [span^{p242}](#), [strong^{p211}](#), [sub^{p235}](#), [sup^{p235}](#), [svg^{p396}](#), [table^{p398}](#), [textarea^{p508}](#), [time^{p227}](#), [u^{p237}](#), [ul^{p197}](#) (if the element's children include at least one [li^{p198}](#) element), [var^{p232}](#), [video^{p317}](#), [text^{p116}](#) that is not [inter-element whitespace^{p113}](#)

3.2.4.2.9 Script-supporting elements

Script-supporting elements are those that do not [represent^{p111}](#) anything themselves (i.e. they are not rendered), but are used to support scripts, e.g. to provide functionality for the user.

The following elements are script-supporting elements:

⇒ [script^{p591}](#), [template^{p604}](#)

3.2.4.3 Transparent content models

Some elements are described as **transparent**; they have "transparent" in the description of their content model. The content model of a [transparent^{p117}](#) element is derived from the content model of its parent element: the elements required in the part of the content model that is "transparent" are the same elements as required in the part of the content model of the parent of the transparent element in which the transparent element finds itself.

Example

For instance, an [ins^{p260}](#) element inside a [ruby^{p219}](#) element cannot contain an [rt^{b225}](#) element, because the part of the [ruby^{p219}](#) element's content model that allows [ins^{p260}](#) elements is the part that allows [phrasing content^{p116}](#), and the [rt^{b225}](#) element is not [phrasing content^{p116}](#).

Note

In some cases, where transparent elements are nested in each other, the process has to be applied iteratively.

Example

Consider the following markup fragment:

```
<p><object><param><ins><map><a href="/">Apples</a></map></ins></object></p>
```

To check whether "Apples" is allowed inside the [a^{p208}](#) element, the content models are examined. The [a^{p208}](#) element's content model is transparent, as is the [map^{p389}](#) element's, as is the [ins^{p260}](#) element's, as is the part of the [object^{p310}](#) element's in which the [ins^{p260}](#) element is found. The [object^{p310}](#) element is found in the [p^{p187}](#) element, whose content model is [phrasing content^{p116}](#). Thus, "Apples" is allowed, as text is phrasing content.

When a transparent element has no parent, then the part of its content model that is "transparent" must instead be treated as accepting any [flow content^{p115}](#).

3.2.4.4 Paragraphs

Note *The term [paragraph^{p118}](#) as defined in this section is used for more than just the definition of the [p^{p187}](#) element. The [paragraph^{p118}](#) concept defined here is used to describe how to interpret documents. The [p^{p187}](#) element is merely one of several ways of marking up a [paragraph^{p118}](#).*

A **paragraph** is typically a run of [phrasing content^{p116}](#) that forms a block of text with one or more sentences that discuss a particular topic, as in typography, but can also be used for more general thematic grouping. For instance, an address is also a paragraph, as is a part of a form, a byline, or a stanza in a poem.

Example

In the following example, there are two paragraphs in a section. There is also a heading, which contains phrasing content that is not a paragraph. Note how the comments and [inter-element whitespace^{p113}](#) do not form paragraphs.

```
<section>
  <h1>Example of paragraphs</h1>
  This is the <em>first</em> paragraph in this example.
  <p>This is the second.</p>
  <!-- This is not a paragraph. -->
</section>
```

Paragraphs in [flow content^{p115}](#) are defined relative to what the document looks like without the [a^{p208}](#), [ins^{p260}](#), [del^{p262}](#), and [map^{p389}](#) elements complicating matters, since those elements, with their hybrid content models, can straddle paragraph boundaries, as shown in the first two examples below.

Note *Generally, having elements straddle paragraph boundaries is best avoided. Maintaining such markup can be difficult.*

Example

The following example takes the markup from the earlier example and puts [ins^{p260}](#) and [del^{p262}](#) elements around some of the markup to show that the text was changed (though in this case, the changes admittedly don't make much sense). Notice how this example has exactly the same paragraphs as the previous one, despite the [ins^{p260}](#) and [del^{p262}](#) elements — the [ins^{p260}](#) element straddles the heading and the first paragraph, and the [del^{p262}](#) element straddles the boundary between the two paragraphs.

```
<section>
  <ins><h1>Example of paragraphs</h1>
  This is the <em>first</em> paragraph in</ins> this example<del>.
  <p>This is the second.</p></del>
  <!-- This is not a paragraph. -->
</section>
```

Let *view* be a view of the DOM that replaces all [a^{p208}](#), [ins^{p260}](#), [del^{p262}](#), and [map^{p389}](#) elements in the document with their [contents^{p113}](#). Then, in *view*, for each run of sibling [phrasing content^{p116}](#) nodes uninterrupted by other types of content, in an element that accepts content other than [phrasing content^{p116}](#) as well as [phrasing content^{p116}](#), let *first* be the first node of the run, and let *last* be the last node of the run. For each such run that consists of at least one node that is neither [embedded content^{p116}](#) nor [inter-element whitespace^{p113}](#), a paragraph exists in the original DOM from immediately before *first* to immediately after *last*. (Paragraphs can thus span across [a^{p208}](#), [ins^{p260}](#), [del^{p262}](#), and [map^{p389}](#) elements.)

Conformance checkers may warn authors of cases where they have paragraphs that overlap each other (this can happen with [object^{p310}](#), [video^{p317}](#), [audio^{p321}](#), and [canvas^{p607}](#) elements, and indirectly through elements in other namespaces that allow HTML to be further embedded therein, like [svg^{p396}](#) or [math^{p395}](#)).

A [paragraph](#)^{p118} is also formed explicitly by [p](#)^{p187} elements.

Note The [p](#)^{p187} element can be used to wrap individual paragraphs when there would otherwise not be any content other than phrasing content to separate the paragraphs from each other.

Example

In the following example, the link spans half of the first paragraph, all of the heading separating the two paragraphs, and half of the second paragraph. It straddles the paragraphs and the heading.

```
<header>
  Welcome!
  <a href="about.html">
    This is home of...
    <h1>The Falcons!</h1>
    The Lockheed Martin multirole jet fighter aircraft!
  </a>
  This page discusses the F-16 Fighting Falcon's innermost secrets.
</header>
```

Here is another way of marking this up, this time showing the paragraphs explicitly, and splitting the one link element into three:

```
<header>
  <p>Welcome! <a href="about.html">This is home of...</a></p>
  <h1><a href="about.html">The Falcons!</a></h1>
  <p><a href="about.html">The Lockheed Martin multirole jet
  fighter aircraft!</a> This page discusses the F-16 Fighting
  Falcon's innermost secrets.</p>
</header>
```

Example

It is possible for paragraphs to overlap when using certain elements that define fallback content. For example, in the following section:

```
<section>
  <h1>My Cats</h1>
  You can play with my cat simulator.
  <object data="cats.sim">
    To see the cat simulator, use one of the following links:
    <ul>
      <li><a href="cats.sim">Download simulator file</a>
      <li><a href="http://sims.example.com/watch?v=LYds5xY4INU">Use online simulator</a>
    </ul>
    Alternatively, upgrade to the Mellblom Browser.
  </object>
  I'm quite proud of it.
</section>
```

There are five paragraphs:

1. The paragraph that says "You can play with my cat simulator. [object](#) I'm quite proud of it.", where [object](#) is the [object](#)^{b310} element.
2. The paragraph that says "To see the cat simulator, use one of the following links:".
3. The paragraph that says "Download simulator file".
4. The paragraph that says "Use online simulator".
5. The paragraph that says "Alternatively, upgrade to the Mellblom Browser.".

The first paragraph is overlapped by the other four. A user agent that supports the "cats.sim" resource will only show the first one, but a user agent that shows the fallback will confusingly show the first sentence of the first paragraph as if it was in the same paragraph as the second one, and will show the last paragraph as if it was at the start of the second sentence of the first paragraph.

To avoid this confusion, explicit [p](#)^{p187} elements can be used. For example:

```
<section>
  <h1>My Cats</h1>
  <p>You can play with my cat simulator.</p>
```

```

<object data="cats.sim">
  <p>To see the cat simulator, use one of the following links:</p>
  <ul>
    <li><a href="cats.sim">Download simulator file</a>
    <li><a href="http://sims.example.com/watch?v=LYds5xY4INU">Use online simulator</a>
  </ul>
  <p>Alternatively, upgrade to the Mellblom Browser.</p>
</object>
<p>I'm quite proud of it.</p>

```

3.2.5 Global attributes

The following attributes are common to and may be specified on all [HTML elements^{p42}](#) (even those not defined in this specification):

- [accesskey^{p738}](#)
- [class^{p128}](#)
- [contenteditable^{p739}](#)
- [contextmenu^{p577}](#)
- [dir^{p125}](#)
- [draggable^{p758}](#)
- [dropzone^{p759}](#)
- [hidden^{p723}](#)
- [id^{p122}](#)
- [itemid^{p690}](#)
- [itemprop^{p692}](#)
- [itemref^{p690}](#)
- [itemscope^{p689}](#)
- [itemtype^{p689}](#)
- [lang^{p123}](#)
- [spellcheck^{p741}](#)
- [style^{p128}](#)
- [tabindex^{p729}](#)
- [title^{p122}](#)
- [translate^{p124}](#)

These attributes are only defined by this specification as attributes for [HTML elements^{p42}](#). When this specification refers to elements having these attributes, elements from namespaces that are not defined as having these attributes must not be considered as being elements with these attributes.

Example

For example, in the following XML fragment, the "bogus" element does not have a [dir^{p125}](#) attribute as defined in this specification, despite having an attribute with the literal name "dir". Thus, [the directionality^{p125}](#) of the inner-most [span^{p242}](#) element is '[rtl^{p125}](#)', inherited from the [div^{p207}](#) element indirectly through the "bogus" element.

```

<div xmlns="http://www.w3.org/1999/xhtml" dir="rtl">
  <bogus xmlns="http://example.net/ns" dir="ltr">
    <span xmlns="http://www.w3.org/1999/xhtml">
      </span>
    </bogus>
  </div>

```

To enable assistive technology products to expose a more fine-grained interface than is otherwise possible with HTML elements and attributes, a set of [annotations for assistive technology products^{p132}](#) can be specified (the ARIA [role^{p54}](#) and [aria-*^{p55}](#) attributes). [\[ARIA\]^{p1148}](#)

The following [event handler content attributes^{p839}](#) may be specified on any [HTML element^{p42}](#):

- [onabort^{p843}](#)
- [onautocomplete^{p843}](#)
- [onautocompleteerror^{p843}](#)
- [onblur^{p844*}](#)
- [oncancel^{p843}](#)

- oncanplay^{p843}
- oncanplaythrough^{p843}
- onchange^{p843}
- onclick^{p843}
- onclose^{p843}
- oncontextmenu^{p843}
- oncuechange^{p843}
- ondblclick^{p843}
- ondrag^{p843}
- ondragend^{p843}
- ondragenter^{p843}
- ondragexit^{p843}
- ondragleave^{p843}
- ondragover^{p843}
- ondragstart^{p843}
- ondrop^{p843}
- ondurationchange^{p843}
- onemptied^{p843}
- onended^{p843}
- onerror^{p844*}
- onfocus^{p844*}
- oninput^{p843}
- oninvalid^{p843}
- onkeydown^{p843}
- onkeypress^{p843}
- onkeyup^{p843}
- onload^{p844*}
- onloadeddata^{p843}
- onloadedmetadata^{p843}
- onloadstart^{p843}
- onmousedown^{p843}
- onmouseenter^{p843}
- onmouseleave^{p843}
- onmousemove^{p843}
- onmouseout^{p843}
- onmouseover^{p843}
- onmouseup^{p843}
- onmousewheel^{p843}
- onpause^{p843}
- onplay^{p843}
- onplaying^{p843}
- onprogress^{p843}
- onratechange^{p843}
- onreset^{p843}
- onresize^{p844*}
- onscroll^{p844*}
- onseeked^{p843}
- onseeking^{p843}
- onselect^{p844}
- onshow^{p844}
- onsort^{p844}
- onstalled^{p844}
- onsubmit^{p844}
- onsuspend^{p844}
- ontimeupdate^{p844}
- ontoggle^{p844}
- onvolumechange^{p844}
- onwaiting^{p844}

Note The attributes marked with an asterisk have a different meaning when specified on body^{p157} elements as those elements expose event handlers^{p839} of the Window^{p768} object with the same names.

Note While these attributes apply to all elements, they are not useful on all elements. For example, only media elements^{p326} will ever receive a volumechange^{p387} event fired by the user agent.

Custom data attributes^{p128} (e.g. data-foldername or data-msgid) can be specified on any HTML element^{p42}, to store custom data specific to the page.

In [HTML documents](#)^{p51}, elements in the [HTML namespace](#)^{p101} may have an `xmlns` attribute specified, if, and only if, it has the exact value "`http://www.w3.org/1999/xhtml`". This does not apply to [XML documents](#)^{p51}.

Note In HTML, the `xmlns` attribute has absolutely no effect. It is basically a talisman. It is allowed merely to make migration to and from XHTML mildly easier. When parsed by an [HTML parser](#)^{p952}, the attribute ends up in no namespace, not the "`http://www.w3.org/2000/xmlns/`" namespace like namespace declaration attributes in XML do.

Note In XML, an `xmlns` attribute is part of the namespace declaration mechanism, and an element cannot actually have an `xmlns` attribute in no namespace specified.

The XML specification also allows the use of the `xml:space`^{p48} attribute in the [XML namespace](#)^{p101} on any element in an [XML document](#)^{p51}. This attribute has no effect on [HTML elements](#)^{p42}, as the default behaviour in HTML is to preserve whitespace. [XML]^{p1154}

Note There is no way to serialise the `xml:space`^{p48} attribute on [HTML elements](#)^{p42} in the `text/html`^{p1116} syntax.

3.2.5.1 The `id` attribute

Spec bugs: [17298](#)

The `id`^{p122} attribute specifies its element's [unique identifier \(ID\)](#)^{p51}. [DOM]^{p1149}

The value must be unique amongst all the [IDs](#)^{p51} in the element's [home subtree](#)^{p42} and must contain at least one character. The value must not contain any [space characters](#)^{p58}.

Note There are no other restrictions on what form an ID can take; in particular, IDs can consist of just digits, start with a digit, start with an underscore, consist of just punctuation, etc.

Note An element's [unique identifier](#)^{p51} can be used for a variety of purposes, most notably as a way to link to specific parts of a document using fragment identifiers, as a way to target an element when scripting, and as a way to style a specific element from CSS.

Identifiers are opaque strings. Particular meanings should not be derived from the value of the `id`^{p122} attribute.

3.2.5.2 The `title`^{p122} attribute

The `title` attribute [represents](#)^{p111} advisory information for the element, such as would be appropriate for a tooltip. On a link, this could be the title or a description of the target resource; on an image, it could be the image credit or a description of the image; on a paragraph, it could be a footnote or commentary on the text; on a citation, it could be further information about the source; on [interactive content](#)^{p116}, it could be a label for, or instructions for, use of the element; and so forth. The value is text.

Note Relying on the `title`^{p122} attribute is currently discouraged as many user agents do not expose the attribute in an accessible manner as required by this specification (e.g. requiring a pointing device such as a mouse to cause a tooltip to appear, which excludes keyboard-only users and touch-only users, such as anyone with a modern phone or tablet).

If this attribute is omitted from an element, then it implies that the `title`^{p122} attribute of the nearest ancestor [HTML element](#)^{p42} with a `title`^{p122} attribute set is also relevant to this element. Setting the attribute overrides this, explicitly stating that the advisory information of any ancestors is not relevant to this element. Setting the attribute to the empty string indicates that the element has no advisory information.

If the `title`^{p122} attribute's value contains U+000A LINE FEED (LF) characters, the content is split into multiple lines. Each U+000A LINE FEED (LF) character represents a line break.

Example

Caution is advised with respect to the use of newlines in `title`^{p122} attributes.

For instance, the following snippet actually defines an abbreviation's expansion *with a line break in it*:

```
<p>My logs show that there was some interest in <abbr title="Hypertext  
Transport Protocol">HTTP</abbr> today.</p>
```

Some elements, such as [link^{p141}](#), [abbr^{p218}](#), and [input^{p452}](#), define additional semantics for the [title^{p122}](#) attribute beyond the semantics described above.

The **advisory information** of an element is the value that the following algorithm returns, with the algorithm being aborted once a value is returned. When the algorithm returns the empty string, then there is no advisory information.

1. If the element is a [link^{p141}](#), [style^{p154}](#), [dfn^{p217}](#), [abbr^{p218}](#), or [menuitem^{p574}](#) element, then: if the element has a [title](#) attribute, return the value of that attribute, otherwise, return the empty string.
2. Otherwise, if the element has a [title^{p122}](#) attribute, then return its value.
3. Otherwise, if the element has a parent element, then return the parent element's [advisory information^{p123}](#).
4. Otherwise, return the empty string.

User agents should inform the user when elements have [advisory information^{p123}](#), otherwise the information would not be discoverable.

The [title](#) IDL attribute must [reflect^{p88}](#) the [title^{p122}](#) content attribute.

Spec bugs: [23626](#)

3.2.5.3 The [lang^{p123}](#) and [xml:lang^{p123}](#) attributes

The [lang](#) attribute (in no namespace) specifies the primary language for the element's contents and for any of the element's attributes that contain text. Its value must be a valid BCP 47 language tag, or the empty string. Setting the attribute to the empty string indicates that the primary language is unknown. [\[BCP47\]^{p1148}](#)

The [lang](#) attribute in the [XML namespace^{p101}](#) is defined in XML. [\[XML\]^{p1154}](#)

If these attributes are omitted from an element, then the language of this element is the same as the language of its parent element, if any.

The [lang^{p123}](#) attribute in no namespace may be used on any [HTML element^{p42}](#).

The [lang attribute in the XML namespace^{p123}](#) may be used on [HTML elements^{p42}](#) in [XML documents^{p51}](#), as well as elements in other namespaces if the relevant specifications allow it (in particular, MathML and SVG allow [Lang attributes in the XML namespace^{p123}](#) to be specified on their elements). If both the [lang^{p123}](#) attribute in no namespace and the [lang attribute in the XML namespace^{p123}](#) are specified on the same element, they must have exactly the same value when compared in an [ASCII case-insensitive^{p58}](#) manner.

Authors must not use the [lang attribute in the XML namespace^{p123}](#) on [HTML elements^{p42}](#) in [HTML documents^{p51}](#). To ease migration to and from XHTML, authors may specify an attribute in no namespace with no prefix and with the literal localname "`xml:lang`" on [HTML elements^{p42}](#) in [HTML documents^{p51}](#), but such attributes must only be specified if a [lang^{p123}](#) attribute in no namespace is also specified, and both attributes must have the same value when compared in an [ASCII case-insensitive^{p58}](#) manner.

Note *The attribute in no namespace with no prefix and with the literal localname "`xml:lang`" has no effect on language processing.*

To determine the **language** of a node, user agents must look at the nearest ancestor element (including the element itself if the node is an element) that has a [lang attribute in the XML namespace^{p123}](#) set or is an [HTML element^{p42}](#) and has a [lang^{p123}](#) in no namespace attribute set. That attribute specifies the language of the node (regardless of its value).

If both the [lang^{p123}](#) attribute in no namespace and the [lang attribute in the XML namespace^{p123}](#) are set on an element, user agents must use the [lang attribute in the XML namespace^{p123}](#), and the [lang^{p123}](#) attribute in no namespace must be [ignored^{p42}](#) for the purposes of determining the element's language.

If neither the node nor any of the node's ancestors, including the [root element^{p42}](#), have either attribute set, but there is a [pragma-set default language^{p149}](#) set, then that is the language of the node. If there is no [pragma-set default language^{p149}](#) set, then language information from a higher-level protocol (such as HTTP), if any, must be used as the final fallback language instead. In the absence of any such language information, and in cases where the higher-level protocol reports multiple languages, the language of the node is unknown, and the corresponding language tag is the empty string.

⋮

If the resulting value is not a recognised language tag, then it must be treated as an unknown language having the given language tag, distinct from all other languages. For the purposes of round-tripping or communicating with other services that expect language tags, user agents should pass unknown language tags through unmodified, and tagged as being BCP 47 language tags, so that subsequent services do not interpret the data as another type of language description. [BCP47]^{p1148}

Example Thus, for instance, an element with `lang="xyzzy"` would be matched by the selector `:lang(xyzzy)` (e.g. in CSS), but it would not be matched by `:lang(abcd)`, even though both are equally invalid. Similarly, if a Web browser and screen reader working in unison communicated about the language of the element, the browser would tell the screen reader that the language was "xyzzy", even if it knew it was invalid, just in case the screen reader actually supported a language with that tag after all. Even if the screen reader supported both BCP 47 and another syntax for encoding language names, and in that other syntax the string "xyzzy" was a way to denote the Belarusian language, it would be *incorrect* for the screen reader to then start treating text as Belarusian, because "xyzzy" is not how Belarusian is described in BCP 47 codes (BCP 47 uses the code "be" for Belarusian).

If the resulting value is the empty string, then it must be interpreted as meaning that the language of the node is explicitly unknown.

User agents may use the element's language to determine proper processing or rendering (e.g. in the selection of appropriate fonts or pronunciations, for dictionary selection, or for the user interfaces of form controls such as date pickers).

The `lang` IDL attribute must [reflect^{p88}](#) the `langp123` content attribute in no namespace.

3.2.5.4 The `translatep124` attribute

The `translate` attribute is an [enumerated attribute^{p60}](#) that is used to specify whether an element's attribute values and the values of its `Textp51` node children are to be translated when the page is localized, or whether to leave them unchanged.

The attribute's keywords are the empty string, `yes`, and `no`. The empty string and the `yes` keyword map to the `yes` state. The `no` keyword maps to the `no` state. In addition, there is a third state, the `inherit` state, which is the [missing value default^{p60}](#) (and the [invalid value default^{p60}](#)).

Each element (even non-HTML elements) has a **translation mode**, which is in either the `translate-enabledp124` state or the `no-translatep124` state. If an [HTML element^{p42}](#)'s `translatep124` attribute is in the `yes` state, then the element's `translation modep124` is in the `translate-enabledp124` state; otherwise, if the element's `translatep124` attribute is in the `no` state, then the element's `translation modep124` is in the `no-translatep124` state. Otherwise, either the element's `translatep124` attribute is in the `inherit` state, or the element is not an [HTML element^{p42}](#) and thus does not have a `translatep124` attribute; in either case, the element's `translation modep124` is in the same state as its parent element's, if any, or in the `translate-enabledp124` state, if the element is a [root element^{p42}](#).

When an element is in the `translate-enabled` state, the element's [translatable attributes^{p124}](#) and the values of its `Textp51` node children are to be translated when the page is localized.

When an element is in the `no-translate` state, the element's attribute values and the values of its `Textp51` node children are to be left as-is when the page is localized, e.g. because the element contains a person's name or the name of a computer program.

The following attributes are **translatable attributes**:

- `abbrp415` on `thp414` elements
- `alt` on `areab391`, `imgb273`, and `inputp480` elements
- `contentp146` on `metab145` elements, if the `namep146` attribute specifies a metadata name whose value is known to be translatable
- `downloadp246` on `ap208` and `areap390` elements
- `label` on `menuitemp575`, `menup572`, `optgroupb505`, `optionp506`, and `trackp325` elements
- `langp123` on [HTML elements^{p42}](#); must be "translated" to match the language used in the translation
- `placeholder` on `inputp490` and `textareap511` elements
- `srcdocp300` on `iframeb299` elements; must be parsed and recursively processed
- `stylep128` on [HTML elements^{p42}](#); must be parsed and recursively processed (e.g. for the values of 'content' properties)
- `titlep122` on all [HTML elements^{p42}](#)
- `valuep457` on `inputp452` elements with a `typep454` attribute in the `Buttonp482` state or the `Reset Buttonp481` state

Other specifications may define other attributes that are also [translatable attributes^{p124}](#). For example, ARIA would define the `aria-label` attribute as translatable.

The `translate` IDL attribute must, on getting, return true if the element's [translation mode^{p124}](#) is [translate-enabled^{p124}](#), and false otherwise. On setting, it must set the content attribute's value to "yes" if the new value is true, and set the content attribute's value to "no" otherwise.

Example

In this example, everything in the document is to be translated when the page is localized, except the sample keyboard input and sample program output:

```
<!DOCTYPE HTML>
<html> <!-- default on the root element is translate=yes -->
<head>
  <title>The Bee Game</title> <!-- implied translate=yes inherited from ancestors -->
</head>
<body>
  <p>The Bee Game is a text adventure game in English.</p>
  <p>When the game launches, the first thing you should do is type
    <kbd translate=no>eat honey</kbd>. The game will respond with:</p>
    <pre><samp translate=no>Yum yum! That was some good honey!</samp></pre>
</body>
</html>
```

3.2.5.5 The `xml:base` attribute (XML only)

The `xml:basep125` attribute is defined in XML Base. [\[XMLBASE\]^{p1154}](#)

The `xml:basep125` attribute may be used on [HTML elements^{p42}](#) of [XML documents^{p51}](#). Authors must not use the `xml:basep125` attribute on [HTML elements^{p42}](#) in [HTML documents^{p51}](#).

3.2.5.6 The `dir` attribute

The `dirp125` attribute specifies the element's text directionality. The attribute is an [enumerated attribute^{p60}](#) with the following keywords and states:

The `ltr` keyword, which maps to the `ltr` state

Indicates that the contents of the element are explicitly directionally isolated left-to-right text.

The `rtl` keyword, which maps to the `rtl` state

Indicates that the contents of the element are explicitly directionally isolated right-to-left text.

The `auto` keyword, which maps to the `auto` state

Indicates that the contents of the element are explicitly directionally isolated text, but that the direction is to be determined programmatically using the contents of the element (as described below).

Note *The heuristic used by this state is very crude (it just looks at the first character with a strong directionality, in a manner analogous to the Paragraph Level determination in the bidirectional algorithm). Authors are urged to only use this value as a last resort when the direction of the text is truly unknown and no better server-side heuristic can be applied. [IDI]^{p1148}*

Note *For `textareap508` and `prep191` elements, the heuristic is applied on a per-paragraph level.*

The attribute has no [invalid value default^{p60}](#) and no [missing value default^{p60}](#).

The **directionality** of an element (any element, not just an [HTML element^{p42}](#)) is either 'ltr' or 'rtl', and is determined as per the first appropriate set of steps from the following list:

- ↪ If the element's `dirp125` attribute is in the `ltrp125` state
- ↪ If the element is a `root elementp42` and the `dirp125` attribute is not in a defined state (i.e. it is not present or has an invalid value)
- ↪ If the element is an `inputp452` element whose `typep454` attribute is in the `Telephonep459` state, and the `dirp125` attribute is not in a defined state (i.e. it is not present or has an invalid value)

`The directionalityp125` of the element is '`ltrp125`'.
- ↪ If the element's `dirp125` attribute is in the `rtlp125` state

`The directionalityp125` of the element is '`rtlp125`'.
- ↪ If the element is an `inputp452` element whose `typep454` attribute is in the `Textp458`, `Searchp458`, `Telephonep459`, `URLp460`, or `E-mailp461` state, and the `dirp125` attribute is in the `autop125` state
- ↪ If the element is a `textareap508` element and the `dirp125` attribute is in the `autop125` state

If the element's `valuep527` contains a character of bidirectional character type AL or R, and there is no character of bidirectional character type L anywhere before it in the element's `valuep527`, then `the directionalityp125` of the element is '`rtlp125`'. [BIDI]^{p1148}

Otherwise, if the element's `valuep527` is not the empty string, or if the element is a `root elementp42`, `the directionalityp125` of the element is '`ltrp125`'.

Otherwise, `the directionalityp125` of the element is the same as the element's parent element's `directionalityp125`.
- ↪ If the element's `dirp125` attribute is in the `autop125` state
- ↪ If the element is a `bdip240` element and the `dirp125` attribute is not in a defined state (i.e. it is not present or has an invalid value)

Find the first character in `tree orderp42` that matches the following criteria:

 - The character is from a `Textp51` node that is a descendant of the element whose `directionalityp125` is being determined.
 - The character is of bidirectional character type L, AL, or R. [BIDI]^{p1148}
 - The character is not in a `Textp51` node that has an ancestor element that is a descendant of the element whose `directionalityp125` is being determined and that is either:
 - A `bdip240` element.
 - A `scriptp591` element.
 - A `stylep154` element.
 - A `textareap508` element.
 - An element with a `dirp125` attribute in a defined state.

If such a character is found and it is of bidirectional character type AL or R, `the directionalityp125` of the element is '`rtlp125`'.

If such a character is found and it is of bidirectional character type L, `the directionalityp125` of the element is '`ltrp125`'.

Otherwise, if the element is a `root elementp42`, `the directionalityp125` of the element is '`ltrp125`'.

Otherwise, `the directionalityp125` of the element the same as the element's parent element's `directionalityp125`.

- ↪ If the element has a parent element and the `dirp125` attribute is not in a defined state (i.e. it is not present or has an invalid value)

`The directionalityp125` of the element is the same as the element's parent element's `directionalityp125`.

Note Since the `dirp125` attribute is only defined for `HTML elementsp42`, it cannot be present on elements from other namespaces. Thus, elements from other namespaces always just inherit their `directionalityp125` from their parent element, or, if they don't have one, default to '`ltrp125`'.

Note This attribute has rendering requirements involving the bidirectional algorithm^{p132}.

The **directionality of an attribute** of an `HTML elementp42`, which is used when the text of that attribute is to be included in the rendering in some manner, is determined as per the first appropriate set of steps from the following list:

- ↪ If the attribute is a `directionality-capable attributep127` and the element's `dirp125` attribute is in the `autop125` state

Find the first character (in logical order) of the attribute's value that is of bidirectional character type L, AL, or R. [BIDI]^{p1148}

If such a character is found and it is of bidirectional character type AL or R, the `directionality of the attributep126` is '`rtlp125`'.

Otherwise, the [directionality of the attribute](#)^{p126} is '[ltr](#)'.

↪ Otherwise

The [directionality of the attribute](#)^{p126} is the same as [the element's directionality](#)^{p125}.

The following attributes are **directionality-capable attributes**:

- [abbr](#)^{p415} on [th](#)^{p414} elements
- [alt](#) on [area](#)^{p391}, [img](#)^{p273}, and [input](#)^{p480} elements
- [content](#)^{p146} on [meta](#)^{p145} elements, if the [name](#)^{p146} attribute specifies a metadata name whose value is primarily intended to be human-readable rather than machine-readable
- [label](#) on [menuitem](#)^{p375}, [menu](#)^{p572}, [optgroup](#)^{p505}, [option](#)^{p506}, and [track](#)^{p325} elements
- [placeholder](#) on [input](#)^{p490} and [textarea](#)^{p511} elements
- [title](#)^{p122} on all [HTML elements](#)^{p42}

Note

`document.dirp127 [= value]`

Returns [the html element](#)^{p105}'s [dir](#)^{p125} attribute's value, if any.

Can be set, to either "ltr", "rtl", or "auto" to replace [the html element](#)^{p105}'s [dir](#)^{p125} attribute's value.

If there is no [html element](#)^{p105}, returns the empty string and ignores new values.

The [dir](#) IDL attribute on an element must [reflect](#)^{p88} the [dir](#)^{p125} content attribute of that element, [limited to only known values](#)^{p89}.

The [dir](#) IDL attribute on [Document](#)^{p102} objects must [reflect](#)^{p88} the [dir](#)^{p125} content attribute of [the html element](#)^{p105}, if any, [limited to only known values](#)^{p89}. If there is no such element, then the attribute must return the empty string and do nothing on setting.

Note Authors are strongly encouraged to use the [dir](#)^{p125} attribute to indicate text direction rather than using CSS, since that way their documents will continue to render correctly even in the absence of CSS (e.g. as interpreted by search engines).

Example

This markup fragment is of an IM conversation.

```
<p dir=auto class="u1"><b><bdi>Student</bdi></b> How do you write "What's your name?" in Arabic?</p>
<p dir=auto class="u2"><b><bdi>Teacher</bdi></b> ماتسماك؟</p>
<p dir=auto class="u1"><b><bdi>Student</bdi></b> Thanks.</p>
<p dir=auto class="u2"><b><bdi>Teacher</bdi></b> That's written "شكراً".</p>
<p dir=auto class="u2"><b><bdi>Teacher</bdi></b> Do you know how to write "Please"?</p>
<p dir=auto class="u1"><b><bdi>Student</bdi></b> من فضلك", right?</p>
```

Given a suitable style sheet and the default alignment styles for the [p](#)^{p187} element, namely to align the text to the *start edge* of the paragraph, the resulting rendering could be as follows:

Student: How do you write "What's your name?" in Arabic?
Teacher: ما اسمك؟
Student: Thanks.
Teacher: That's written "شكراً".
Teacher: Do you know how to write "Please"?
Student: من فضلك", right?

As noted earlier, the [auto](#)^{p125} value is not a panacea. The final paragraph in this example is misinterpreted as being right-to-left text, since it begins with an Arabic character, which causes the "right?" to be to the left of the Arabic text.

3.2.5.7 The `class` attribute

Every [HTML element^{p42}](#) may have a `classp128` attribute specified.

The attribute, if specified, must have a value that is a [set of space-separated tokens^{p80}](#) representing the various classes that the element belongs to.

The classes that an [HTML element^{p42}](#) has assigned to it consists of all the classes returned when the value of the `classp128` attribute is [split on spaces^{p80}](#). (Duplicates are ignored.)

Note Assigning classes to an element affects class matching in selectors in CSS, the [getElementsByClassName\(\)^{p51}](#) method in the DOM, and other such features.

There are no additional restrictions on the tokens authors can use in the `classp128` attribute, but authors are encouraged to use values that describe the nature of the content, rather than values that describe the desired presentation of the content.

Note The `className` and `classList` IDL attributes, defined in the DOM specification, reflect^{p88} the `classp128` content attribute. [\[DOM\]^{p1149}](#)

3.2.5.8 The `style` attribute

All [HTML elements^{p42}](#) may have the `stylep128` content attribute set. This is a [CSS styling attribute^{p53}](#) as defined by the CSS Styling Attribute Syntax specification. [\[CSSATTR\]^{p1149}](#)

In user agents that support CSS, the attribute's value must be parsed when the attribute is added or has its value changed, according to the rules given for [CSS styling attributes^{p53}](#). [\[CSSATTR\]^{p1149}](#)

Documents that use `stylep128` attributes on any of their elements must still be comprehensible and usable if those attributes were removed.

Note In particular, using the `stylep128` attribute to hide and show content, or to convey meaning that is otherwise not included in the document, is non-conforming. (To hide and show content, use the [hidden^{p723}](#) attribute.)

Note

`element.stylep128`

Returns a [CSSStyleDeclaration^{p53}](#) object for the element's `stylep128` attribute.

The `style` IDL attribute is defined in the CSS Object Model (CSSOM) specification. [\[CSSOM\]^{p1149}](#)

Example

In the following example, the words that refer to colours are marked up using the `spanp242` element and the `stylep128` attribute to make those words show up in the relevant colours in visual media.

```
<p>My sweat suit is <span style="color: green; background: transparent">green</span> and my eyes are <span style="color: blue; background: transparent">blue</span>.</p>
```

3.2.5.9 Embedding custom non-visible data with the `data-*` attributes

A **custom data attribute** is an attribute in no namespace whose name starts with the string "`data-`", has at least one character and is [XML-compatible^{p42}](#), and contains no [uppercase ASCII letters^{p58}](#).

Note All attribute names on [HTML elements^{p42}](#) in [HTML documents^{p51}](#) get ASCII-lowercased automatically, so the restriction on uppercase letters doesn't affect such documents.

Support:	
Chrome	7+
IE	11+
Chrome for Android	40+
Firefox	6+
iOS Safari	5.0-5.1+
Android Browser	3+
UC Browser for Android	9.9+
Opera Mini (limited)	5.0-8.0+
Safari	5.1+
Opera	11.1+
IE Mobile	11+
Firefox for Android	33+

Source: [caniuse.com](#)

[Custom data attributes](#)^{p128} are intended to store custom data private to the page or application, for which there are no more appropriate attributes or elements.

These attributes are not intended for use by software that is not known to the administrators of the site that uses the attributes. For generic extensions that are to be used by multiple independent tools, either this specification should be extended to provide the feature explicitly, or a technology like [microdata](#)^{p683} should be used (with a standardised vocabulary).

Example

For instance, a site about music could annotate list items representing tracks in an album with custom data attributes containing the length of each track. This information could then be used by the site itself to allow the user to sort the list by track length, or to filter the list for tracks of certain lengths.

```
<ol>
  <li data-length="2m11s">Beyond The Sea</li>
  ...
</ol>
```

It would be inappropriate, however, for the user to use generic software not associated with that music site to search for tracks of a certain length by looking at this data.

This is because these attributes are intended for use by the site's own scripts, and are not a generic extension mechanism for publicly-visible metadata.

Example

Similarly, a page author could write markup that provides information for a translation tool that they are intending to use:

```
<p>The third <span data-mytrans-de="Anspruch">claim</span> covers the case of <span
translate="no">HTML</span> markup.</p>
```

In this example, the "data-mytrans-de" attribute gives specific text for the MyTrans product to use when translating the phrase "claim" to German. However, the standard [translate](#)^{p124} attribute is used to tell it that in all languages, "HTML" is to remain unchanged. When a standard attribute is available, there is no need for a [custom data attribute](#)^{p128} to be used.

Every [HTML element](#)^{p42} may have any number of [custom data attributes](#)^{p128} specified, with any value.

Note

`element.dataset`^{p129}

Returns a [DOMStringMap](#)^{p96} object for the element's [data-*](#)^{p128} attributes.

Hyphenated names become camel-cased. For example, `data-foo-bar=""` becomes `element.dataset.fooBar`.

The [dataset](#) IDL attribute provides convenient accessors for all the [data-*](#)^{p128} attributes on an element. On getting, the [dataset](#)^{p129} IDL attribute must return a [DOMStringMap](#)^{p96} object, associated with the following algorithms, which expose these attributes on their element:

The algorithm for getting the list of name-value pairs

1. Let `list` be an empty list of name-value pairs.
2. For each content attribute on the element whose first five characters are the string "data-" and whose remaining characters (if any) do not include any [uppercase ASCII letters](#)^{p58}, in the order that those attributes are listed in the element's [attribute list](#)^{p51}, add a name-value pair to `list` whose name is the attribute's name with the first five characters removed and whose value is the attribute's value.
3. For each name in `list`, for each U+002D HYPHEN-MINUS character (-) in the name that is followed by a [lowercase ASCII letter](#)^{p58}, remove the U+002D HYPHEN-MINUS character (-) and replace the character that followed it by the same character [converted to ASCII uppercase](#)^{p58}.
4. Return `list`.

The algorithm for setting names to certain values

1. Let `name` be the name passed to the algorithm.

2. Let *value* be the value passed to the algorithm.
3. If *name* contains a U+002D HYPHEN-MINUS character (-) followed by a [lowercase ASCII letter](#)^{p58}, throw a [SyntaxError](#)^{p50} exception and abort these steps.
4. For each [uppercase ASCII letter](#)^{p58} in *name*, insert a U+002D HYPHEN-MINUS character (-) before the character and replace the character with the same character [converted to ASCII lowercase](#)^{p58}.
5. Insert the string `data-` at the front of *name*.
6. Set the value of the attribute with the name *name*, to the value *value*, replacing any previous value if the attribute already existed. If `setAttribute()` would have thrown an exception when setting an attribute with the name *name*, then this must throw the same exception.

The algorithm for deleting names

1. Let *name* be the name passed to the algorithm.
2. For each [uppercase ASCII letter](#)^{p58} in *name*, insert a U+002D HYPHEN-MINUS character (-) before the character and replace the character with the same character [converted to ASCII lowercase](#)^{p58}.
3. Insert the string `data-` at the front of *name*.
4. Remove the attribute with the name *name*, if such an attribute exists. Do nothing otherwise.

Note *This algorithm will only get invoked by the Web IDL specification for names that are given by the earlier algorithm for getting the list of name-value pairs. [WEBIDL](#)*^{p1154}

Example

If a Web page wanted an element to represent a space ship, e.g. as part of a game, it would have to use the [class](#)^{p128} attribute along with [data-*](#)^{p128} attributes:

```
<div class="spaceship" data-ship-id="92432"
    data-weapons="laser 2" data-shields="50%"
    data-x="30" data-y="10" data-z="90">
    <button class="fire"
        onclick="spaceships[this.parentNode.dataset.shipId].fire()">
        Fire
    </button>
</div>
```

Notice how the hyphenated attribute name becomes camel-cased in the API.

Authors should carefully design such extensions so that when the attributes are ignored and any associated CSS dropped, the page is still usable.

User agents must not derive any implementation behaviour from these attributes or values. Specifications intended for user agents must not define these attributes to have any meaningful values.

JavaScript libraries may use the [custom data attributes](#)^{p128}, as they are considered to be part of the page on which they are used. Authors of libraries that are reused by many authors are encouraged to include their name in the attribute names, to reduce the risk of clashes. Where it makes sense, library authors are also encouraged to make the exact name used in the attribute names customizable, so that libraries whose authors unknowingly picked the same name can be used on the same page, and so that multiple versions of a particular library can be used on the same page even when those versions are not mutually compatible.

Example

For example, a library called "DoQuery" could use attribute names like `data-doquery-range`, and a library called "jJo" could use attributes names like `data-jjo-range`. The jJo library could also provide an API to set which prefix to use (e.g. `J.setDataPrefix('j2')`, making the attributes have names like `data-j2-range`).

3.2.6 Requirements relating to the bidirectional algorithm

3.2.6.1 Authoring conformance criteria for bidirectional-algorithm formatting characters

[Text content^{p116}](#) in [HTML elements^{p42}](#) with [Text^{p51}](#) nodes in their [contents^{p113}](#), and text in attributes of [HTML elements^{p42}](#) that allow free-form text, may contain characters in the ranges U+202A to U+202E and U+2066 to U+2069 (the bidirectional-algorithm formatting characters). However, the use of these characters is restricted so that any embedding or overrides generated by these characters do not start and end with different parent elements, and so that all such embeddings and overrides are explicitly terminated by a U+202C POP DIRECTIONAL FORMATTING character. This helps reduce incidences of text being reused in a manner that has unforeseen effects on the bidirectional algorithm. [\[BIDI\]^{p1148}](#)

The aforementioned restrictions are defined by specifying that certain parts of documents form [bidirectional-algorithm formatting character ranges^{p131}](#), and then imposing a requirement on such ranges.

The strings resulting from applying the following algorithm to an [HTML element^{p42}](#) *element* are [bidirectional-algorithm formatting character ranges^{p131}](#):

1. Let *output* be an empty list of strings.
2. Let *string* be an empty string.
3. Let *node* be the first child node of *element*, if any, or null otherwise.
4. *Loop*: If *node* is null, jump to the step labeled *end*.
5. Process *node* according to the first matching step from the following list:
 - ↪ **If *node* is a [Text^{p51}](#) node**
Append the text data of *node* to *string*.
 - ↪ **If *node* is a [br^{p242}](#) element**
 - ↪ **If *node* is an [HTML element^{p42}](#) that is [flow content^{p115}](#) but that is not also [phrasing content^{p116}](#)**
If *string* is not the empty string, push *string* onto *output*, and let *string* be empty string.
 - ↪ **Otherwise**
Do nothing.
6. Let *node* be *node*'s next sibling, if any, or null otherwise.
7. Jump to the step labeled *loop*.
8. *End*: If *string* is not the empty string, push *string* onto *output*.
9. Return *output* as the [bidirectional-algorithm formatting character ranges^{p131}](#).

The value of a namespace-less attribute of an [HTML element^{p42}](#) is a [bidirectional-algorithm formatting character range^{p131}](#).

Any strings that, as described above, are [bidirectional-algorithm formatting character ranges](#) must match the `string` production in the following ABNF, the character set for which is Unicode. [\[ABNF\]^{p1148}](#)

```
string      = *( plaintext ( embedding / override / isolation ) ) plaintext
embedding   = ( lre / rle ) string pdf
override    = ( lro / rlo ) string pdf
isolation   = ( lri / rli / fsi ) string pdi
lre         = %x202A ; U+202A LEFT-TO-RIGHT EMBEDDING
rle         = %x202B ; U+202B RIGHT-TO-LEFT EMBEDDING
lro         = %x202D ; U+202D LEFT-TO-RIGHT OVERRIDE
rlo         = %x202E ; U+202E RIGHT-TO-LEFT OVERRIDE
pdf         = %x202C ; U+202C POP DIRECTIONAL FORMATTING
lri         = %x2066 ; U+2066 LEFT-TO-RIGHT ISOLATE
rli         = %x2067 ; U+2067 RIGHT-TO-LEFT ISOLATE
fsi         = %x2068 ; U+2068 FIRST STRONG ISOLATE
pdi         = %x2069 ; U+2069 POP DIRECTIONAL ISOLATE
plaintext   = *( %x0000-2029 / %x202F-2065 / %x206A-10FFFF )
                ; any string with no bidirectional-algorithm formatting characters
```

Note While the U+2069 POP DIRECTIONAL ISOLATE character implicitly also ends open embeddings and overrides, text that relies on this implicit scope closure is not conforming to this specification. All strings of embeddings, overrides, and isolations need to be explicitly terminated to conform to this section's requirements.

Note Authors are encouraged to use the `dir`^{p125} attribute, the `bdo`^{p241} element, and the `bdi`^{p240} element, rather than maintaining the bidirectional-algorithm formatting characters manually. The bidirectional-algorithm formatting characters interact poorly with CSS.

3.2.6.2 User agent conformance criteria

User agents must implement the Unicode bidirectional algorithm to determine the proper ordering of characters when rendering documents and parts of documents. [BIDI]^{p1148}

The mapping of HTML to the Unicode bidirectional algorithm must be done in one of three ways. Either the user agent must implement CSS, including in particular the CSS 'unicode-bidi', 'direction', and 'content' properties, and must have, in its user agent style sheet, the rules using those properties given in this specification's `rendering`^{p1058} section, or, alternatively, the user agent must act as if it implemented just the aforementioned properties and had a user agent style sheet that included all the aforementioned rules, but without letting style sheets specified in documents override them, or, alternatively, the user agent must implement another styling language with equivalent semantics. [CSSWMI]^{p1149} [CSSGC]^{p1149}

The following elements and attributes have requirements defined by the `rendering`^{p1058} section that, due to the requirements in this section, are requirements on all user agents (not just those that [support the suggested default rendering](#)^{p46}):

- `dir`^{p125} attribute
- `bdi`^{p240} element
- `bdo`^{p241} element
- `br`^{p242} element
- `pre`^{p191} element
- `textarea`^{p508} element
- `wbr`^{p243} element

3.2.7 Annotations for assistive technology products (ARIA)

Spec bugs: 28123

Authors may use the ARIA `role`^{p54} and `aria-*`^{p55} attributes on [HTML elements](#)^{p42}, in accordance with the requirements described in the ARIA specifications, except where these conflict with the [strong native semantics](#) or are equal to the [default implicit ARIA semantics](#) described below. These exceptions are intended to prevent authors from making assistive technology products report nonsensical states that do not represent the actual state of the document. [ARIA]^{p1148}

Spec bugs: 10919

Authors must not set the ARIA `role`^{p54} and `aria-*`^{p55} attributes in a manner that conflicts with the semantics described in the following table, except that the `presentation` role may always be used. Authors must not set the ARIA `role`^{p54} and `aria-*`^{p55} attributes to values that match the [default implicit ARIA semantics](#) defined in the following two tables.

User agents must implement ARIA semantics on all [HTML elements](#)^{p42}, as defined in the ARIA specifications. The [default implicit ARIA semantics](#) defined below must be recognised by implementations for the purposes of ARIA processing. [ARIAIMPL]^{p1148}

Note The ARIA attributes defined in the ARIA specifications, and the [strong native semantics](#) and [default implicit ARIA semantics](#) defined below, do not have any effect on CSS pseudo-class matching, user interface modalities that don't use assistive technologies, or the default actions of user interaction events as described in this specification.

The following table defines the [strong native semantics](#) and corresponding [default implicit ARIA semantics](#) that apply to [HTML elements](#)^{p42}. Each language feature (element or attribute) in a cell in the first column implies the ARIA semantics (any role, states, and properties) given in the cell in the second column of the same row. When multiple rows apply to an element, the role from the last row to define a role must be applied, and the states and properties from all the rows must be combined.

Spec bugs: 24272

Language feature	Strong native semantics and default implicit ARIA semantics
<code>area</code> ^{p390} element that creates a hyperlink ^{p245}	<code>link</code> role
<code>base</code> ^{p140} element	No role ^{p136}
<code>datalist</code> ^{p503} element	<code>listbox</code> role, with the <code>aria-multiselectable</code> property set to "false"
<code>details</code> ^{p567} element	<code>aria-expanded</code> state set to "true" if the element's <code>open</code> ^{p567} attribute is present, and set to "false" otherwise
<code>dialog</code> ^{p586} element without an <code>open</code> ^{p586} attribute	The <code>aria-hidden</code> state set to "true"

Language feature	Strong native semantics and default implicit ARIA semantics
<code>fieldset^{p524}</code> element	<code>group</code> role
<code>head^{p138}</code> element	No role ^{p136} , with the <code>aria-hidden</code> state set to "true"
<code>hgroup^{p170}</code> element	<code>heading</code> role, with the <code>aria-level</code> property set to the element's <code>outline depth^{p180}</code>
<code>hr^{p190}</code> element	<code>separator</code> role
<code>html^{p137}</code> element	No role ^{p136}
<code>img^{b272}</code> element whose <code>alt^{p273}</code> attribute's value is empty	<code>presentation</code> role
<code>input^{p452}</code> element with a <code>type^{p454}</code> attribute in the <code>Checkbox^{p475}</code> state	<code>aria-checked</code> state set to "mixed" if the element's <code>indeterminate^{p457}</code> IDL attribute is true, or "true" if the element's <code>checkedness^{p527}</code> is true, or "false" otherwise
<code>input^{p452}</code> element with a <code>type^{p454}</code> attribute in the <code>Colour^{p474}</code> state	No role ^{p136}
<code>input^{p452}</code> element with a <code>type^{p454}</code> attribute in the <code>Date^{p464}</code> state	No role ^{p136} , with the <code>aria-readonly</code> property set to "true" if the element has a <code>readonly^{p483}</code> attribute
<code>input^{p452}</code> element with a <code>type^{p454}</code> attribute in the <code>Date and Time^{p463}</code> state	No role ^{p136} , with the <code>aria-readonly</code> property set to "true" if the element has a <code>readonly^{p483}</code> attribute
<code>input^{p452}</code> element with a <code>type^{p454}</code> attribute in the <code>Local Date and Time^{p468}</code> state	No role ^{p136} , with the <code>aria-readonly</code> property set to "true" if the element has a <code>readonly^{p483}</code> attribute
<code>input^{p452}</code> element with a <code>type^{p454}</code> attribute in the <code>E-mail^{p461}</code> state with no <code>suggestions source element^{p489}</code>	<code>textbox</code> role, with the <code>aria-readonly</code> property set to "true" if the element has a <code>readonly^{p483}</code> attribute
<code>input^{p452}</code> element with a <code>type^{p454}</code> attribute in the <code>File Upload^{p476}</code> state	No role ^{p136}
<code>input^{p452}</code> element with a <code>type^{p454}</code> attribute in the <code>Hidden^{p458}</code> state	No role ^{p136}
<code>input^{p452}</code> element with a <code>type^{p454}</code> attribute in the <code>Month^{p465}</code> state	No role ^{p136} , with the <code>aria-readonly</code> property set to "true" if the element has a <code>readonly^{p483}</code> attribute
<code>input^{p452}</code> element with a <code>type^{p454}</code> attribute in the <code>Number^{p469}</code> state	<code>spinbutton</code> role, with the <code>aria-readonly</code> property set to "true" if the element has a <code>readonly^{p483}</code> attribute, the <code>aria-valuemax</code> property set to the element's <code>maximum^{p487}</code> , the <code>aria-valuemin</code> property set to the element's <code>minimum^{p487}</code> , and, if the result of applying the <code>rules for parsing floating-point number values^{b62}</code> to the element's <code>value^{p527}</code> is a number, with the <code>aria-valuenow</code> property set to that number
<code>input^{p452}</code> element with a <code>type^{p454}</code> attribute in the <code>Password^{p462}</code> state	<code>textbox</code> role, with the <code>aria-readonly</code> property set to "true" if the element has a <code>readonly^{p483}</code> attribute
<code>input^{p452}</code> element with a <code>type^{p454}</code> attribute in the <code>Radio Button^{b475}</code> state	<code>aria-checked</code> state set to "true" if the element's <code>checkedness^{p527}</code> is true, or "false" otherwise
<code>input^{p452}</code> element with a <code>type^{p454}</code> attribute in the <code>Range^{p470}</code> state and the <code>multiple^{p485}</code> attribute not specified	<code>slider</code> role, with the <code>aria-valuemax</code> property set to the element's <code>maximum^{p487}</code> , the <code>aria-valuemin</code> property set to the element's <code>minimum^{p487}</code> , and the <code>aria-valuenow</code> property set to the result of applying the <code>rules for parsing floating-point number values^{b62}</code> to the element's <code>value^{p527}</code> , if that results in a number, or the <code>default value^{p471}</code> otherwise
<code>input^{p452}</code> element with a <code>type^{p454}</code> attribute in the <code>Range^{p470}</code> state and the <code>multiple^{p485}</code> attribute not specified	<code>aria-valuemax</code> property set to the element's <code>maximum^{p487}</code> , and the <code>aria-valuemin</code> property set to the element's <code>minimum^{p487}</code>
<code>input^{p452}</code> element with a <code>type^{p454}</code> attribute in the <code>Reset Button^{p481}</code> state	<code>button</code> role
<code>input^{p452}</code> element with a <code>type^{p454}</code> attribute in the <code>Search^{p458}</code> state with no <code>suggestions source element^{p489}</code>	<code>textbox</code> role, with the <code>aria-readonly</code> property set to "true" if the element has a <code>readonly^{p483}</code> attribute
<code>input^{p452}</code> element with a <code>type^{p454}</code> attribute in the <code>Submit Button^{p478}</code> state	<code>button</code> role
<code>input^{p452}</code> element with a <code>type^{p454}</code> attribute in the <code>Telephone^{p459}</code> state with no <code>suggestions source element^{p489}</code>	<code>textbox</code> role, with the <code>aria-readonly</code> property set to "true" if the element has a <code>readonly^{p483}</code> attribute
<code>input^{p452}</code> element with a <code>type^{p454}</code> attribute in the <code>Text^{p458}</code> state with no <code>suggestions source element^{p489}</code>	<code>textbox</code> role, with the <code>aria-readonly</code> property set to "true" if the element has a <code>readonly^{p483}</code> attribute
<code>input^{p452}</code> element with a <code>type^{p454}</code> attribute in the <code>Text^{p458}, Search^{p458}, Telephone^{p459}, URL^{p460}, or E-mail^{p461}</code> states with a <code>suggestions source element^{p489}</code>	<code>combobox</code> role, with the <code>aria-owns</code> property set to the same value as the <code>list^{p489}</code> attribute, and the <code>aria-readonly</code> property set to "true" if the element has a <code>readonly^{p483}</code> attribute
<code>input^{p452}</code> element with a <code>type^{p454}</code> attribute in the <code>Time^{p467}</code> state	No role ^{p136} , with the <code>aria-readonly</code> property set to "true" if the element has a <code>readonly^{p483}</code> attribute
<code>input^{p452}</code> element with a <code>type^{p454}</code> attribute in the <code>URL^{p460}</code> state with no <code>suggestions source element^{p489}</code>	<code>textbox</code> role, with the <code>aria-readonly</code> property set to "true" if the element has a <code>readonly^{p483}</code> attribute
<code>input^{p452}</code> element with a <code>type^{p454}</code> attribute in the <code>Week^{b466}</code> state	No role ^{p136} , with the <code>aria-readonly</code> property set to "true" if the element has a <code>readonly^{p483}</code> attribute
<code>input^{p452}</code> element that is <code>required^{p484}</code>	The <code>aria-required</code> state set to "true"

Language feature	Strong native semantics and default implicit ARIA semantics
<code>keygen</code> ^{p513} element	<code>No role</code> ^{p136}
<code>label</code> ^{p451} element	<code>No role</code> ^{p136}
<code>link</code> ^{p141} element that creates a hyperlink ^{b245}	<code>link</code> role
<code>menu</code> ^{p571} element with a <code>type</code> ^{p572} attribute in the <code>popup</code>	<code>No role</code> ^{p136}
<code>menu</code> ^{p572} state	
<code>meta</code> ^{p145} element	<code>No role</code> ^{p136}
<code>meter</code> ^{p519} element	<code>No role</code> ^{p136}
<code>nav</code> ^{p163} element	<code>navigation</code> role
<code>noscript</code> ^{p602} element, when scripting is enabled	<code>No role</code> ^{p136} , with the <code>aria-hidden</code> state set to "true"
<code>optgroup</code> ^{p504} element	<code>No role</code> ^{p136}
<code>option</code> ^{p505} element that is in a list of options ^{b499}	<code>aria-selected</code> and <code>aria-checked</code> states set to "true" if the element's <code>selectedness</code> ^{b507} is true, and "false" otherwise
<code>option</code> ^{p505} element that represents a suggestion in a <code>datalist</code> ^{p503} element or that is in a list of options ^{b499} of a <code>select</code> ^{p498} element with a <code>multiple</code> ^{p499} attribute or a <code>display size</code> ^{p499} greater than 1	<code>option</code> role
<code>param</code> ^{p316} element	<code>No role</code> ^{p136}
<code>progress</code> ^{p518} element	<code>progressbar</code> role, with, if the progress bar is determinate, the <code>aria-valuemax</code> property set to the maximum value of the progress bar, the <code>aria-valuemin</code> property set to zero, and the <code>aria-valuenow</code> property set to the current value of the progress bar
<code>script</code> ^{p591} element	<code>No role</code> ^{p136} , with the <code>aria-hidden</code> state set to "true"
<code>select</code> ^{p498} element with a <code>multiple</code> ^{p499} attribute	<code>listbox</code> role, with the <code>aria-multiselectable</code> property set to "true"
<code>select</code> ^{p498} element with no <code>multiple</code> ^{p499} attribute and with a <code>display size</code> ^{p499} equal to 1	<code>aria-multiselectable</code> property set to "false"
<code>select</code> ^{p498} element with no <code>multiple</code> ^{p499} attribute and with a <code>display size</code> ^{p499} greater than 1	<code>listbox</code> role, with the <code>aria-multiselectable</code> property set to "false"
<code>select</code> ^{p498} element with a <code>required</code> ^{p499} attribute	The <code>aria-required</code> state set to "true"
<code>source</code> ^{p322} element	<code>No role</code> ^{p136}
<code>style</code> ^{p154} element	<code>No role</code> ^{p136} , with the <code>aria-hidden</code> state set to "true"
<code>summary</code> ^{b571} element	<code>No role</code> ^{p136}
<code>table</code> ^{p398} element	<code>grid</code> role with the <code>aria-readonly</code> property set to "true"
<code>tbody</code> ^{p408} element	<code>rowgroup</code> role
<code>td</code> ^{p412} element	<code>gridcell</code> role
<code>template</code> ^{p604} element	<code>No role</code> ^{p136} , with the <code>aria-hidden</code> state set to "true"
<code>textarea</code> ^{p508} element	<code>textbox</code> role, with the <code>aria-multiline</code> property set to "true", and the <code>ariareadonly</code> property set to "true" if the element has a <code>readonly</code> ^{p509} attribute
<code>textarea</code> ^{p508} element with a <code>required</code> ^{p511} attribute	The <code>aria-required</code> state set to "true"
<code>tfoot</code> ^{p410} element	<code>rowgroup</code> role
<code>thead</code> ^{p409} element	<code>rowgroup</code> role
<code>th</code> ^{p414} element that is a sorting-capable th element ^{p423} whose <code>column key ordinality</code> ^{p423} is 1	<code>columnheader</code> role, with the <code>aria-sort</code> state set to "ascending" if the element's <code>column sort direction</code> ^{p423} is <code>normal</code> , and "descending" otherwise.
<code>title</code> ^{p139} element	<code>No role</code> ^{p136}
<code>tr</code> ^{p411} element	<code>row</code> role
Element that is <code>disabled</code> ^{b530}	The <code>aria-disabled</code> state set to "true"
Element that is <code>inert</code> ^{b724}	The <code>aria-hidden</code> state set to "true"
Element with a <code>hidden</code> ^{b723} attribute	The <code>aria-hidden</code> state set to "true"
Element that is a candidate for constraint validation ^{p553} but that does not <code>satisfy its constraints</code> ^{b553}	The <code>aria-invalid</code> state set to "true"

Spec bugs: [22195](#), [25990](#)

Some [HTML elements](#)^{p42} have native semantics that can be overridden. The following table lists these elements and their [default implicit ARIA semantics](#), along with the restrictions that apply to those elements. Each language feature (element or attribute) in a cell in the first column implies, unless otherwise overridden, the ARIA semantic (role, state, or property) given in the cell in the second column of the same row, but this semantic may be overridden under the conditions listed in the cell in the third column of that row. In addition, any element may be given the `presentation` role, regardless of the restrictions below.

Language feature	Default implicit ARIA semantic	Restrictions
<code>a^{p208}</code> element that creates a hyperlink^{p245}	<code>link</code> role	Role must be either <code>link</code> , <code>menuitem</code> , <code>tab</code> , or <code>treeitem</code>
<code>address^{b175}</code> element	<code>No role^{p136}</code>	If specified, role must be <code>contentinfo</code>
<code>article^{p159}</code> element	<code>article</code> role	Role must be either <code>article</code> , <code>document</code> , <code>application</code> , or <code>main</code>
<code>aside^{p166}</code> element	<code>complementary</code> role	Role must be either <code>complementary</code> , <code>note</code> , or <code>search</code>
<code>audio^{p321}</code> element	<code>No role^{p136}</code>	If specified, role must be <code>application</code>
<code>button^{p495}</code> element	<code>button</code> role	Role must be either <code>button</code> , <code>menuitem</code>
<code>details^{b567}</code> element	<code>group</code> role	Role must be a role that supports <code>aria-expanded</code>
<code>dialog^{p586}</code> element	<code>dialog</code> role	Role must be either <code>alert</code> , <code>alertdialog</code> , <code>application</code> , <code>contentinfo</code> , <code>dialog</code> , <code>document</code> , <code>log</code> , <code>main</code> , <code>marquee</code> , <code>region</code> , <code>search</code> , or <code>status</code>
<code>embed^{p307}</code> element	<code>No role^{p136}</code>	If specified, role must be either <code>application</code> , <code>document</code> , or <code>img</code>
<code>footer^{p173}</code> element	<code>No role^{p136}</code>	If specified, role must be <code>contentinfo</code>
<code>h1^{p168}</code> element that does not have an <code>hgroup^{p170}</code> ancestor	<code>heading</code> role, with the <code>aria-level</code> property set to the element's <code>outline depth^{p180}</code>	Role must be either <code>heading</code> or <code>tab</code>
<code>h2^{p168}</code> element that does not have an <code>hgroup^{p170}</code> ancestor	<code>heading</code> role, with the <code>aria-level</code> property set to the element's <code>outline depth^{p180}</code>	Role must be either <code>heading</code> or <code>tab</code>
<code>h3^{p168}</code> element that does not have an <code>hgroup^{p170}</code> ancestor	<code>heading</code> role, with the <code>aria-level</code> property set to the element's <code>outline depth^{p180}</code>	Role must be either <code>heading</code> or <code>tab</code>
<code>h4^{p168}</code> element that does not have an <code>hgroup^{p170}</code> ancestor	<code>heading</code> role, with the <code>aria-level</code> property set to the element's <code>outline depth^{p180}</code>	Role must be either <code>heading</code> or <code>tab</code>
<code>h5^{p168}</code> element that does not have an <code>hgroup^{p170}</code> ancestor	<code>heading</code> role, with the <code>aria-level</code> property set to the element's <code>outline depth^{p180}</code>	Role must be either <code>heading</code> or <code>tab</code>
<code>h6^{p168}</code> element that does not have an <code>hgroup^{p170}</code> ancestor	<code>heading</code> role, with the <code>aria-level</code> property set to the element's <code>outline depth^{p180}</code>	Role must be either <code>heading</code> or <code>tab</code>
<code>header^{p171}</code> element	<code>No role^{p136}</code>	If specified, role must be <code>banner</code>
<code>iframe^{p299}</code> element	<code>No role^{p136}</code>	If specified, role must be either <code>application</code> , <code>document</code> , or <code>img</code>
<code>img^{b272}</code> element whose <code>alt^{p273}</code> attribute's value is absent	<code>img</code> role	No restrictions
<code>img^{b272}</code> element whose <code>alt^{p273}</code> attribute's value is present and not empty	<code>img</code> role	No restrictions
<code>input^{p452}</code> element with a <code>type^{p454}</code> attribute in the <code>Button^{p482}</code> state	<code>button</code> role	Role must be either <code>button</code> , <code>menuitem</code>
<code>input^{p452}</code> element with a <code>type^{p454}</code> attribute in the <code>Checkbox^{p475}</code> state	<code>checkbox</code> role	Role must be either <code>checkbox</code> or <code>menuitemcheckbox</code>
<code>input^{p452}</code> element with a <code>type^{p454}</code> attribute in the <code>Image Button^{p479}</code> state	<code>button</code> role	Role must be either <code>button</code> , <code>menuitem</code>
<code>input^{p452}</code> element with a <code>type^{p454}</code> attribute in the <code>Radio Button^{p475}</code> state	<code>radio</code> role	Role must be either <code>radio</code> or <code>menuitemradio</code>
<code>li^{p198}</code> element whose parent is an <code>ol^{p195}</code> or <code>ul^{p197}</code> element	<code>listitem</code> role	Role must be either <code>listitem</code> , <code>menuitemcheckbox</code> , <code>menuitemradio</code> , <code>option</code> , <code>tab</code> , or <code>treeitem</code>
<code>main^{p205}</code> element	<code>main</code> role	Role must be either <code>document</code> , <code>application</code> , or <code>main</code>
<code>menu^{p571}</code> element with a <code>type^{p572}</code> attribute in the <code>toolbar^{p572}</code> state	<code>toolbar</code> role	Role must be either <code>directory</code> , <code>list</code> , <code>listbox</code> , <code>menu</code> , <code>menubar</code> , <code>tablist</code> , <code>toolbar</code> , or <code>tree</code>
<code>object^{p310}</code> element	<code>No role^{p136}</code>	If specified, role must be either <code>application</code> , <code>document</code> , or <code>img</code>
<code>ol^{p195}</code> element	<code>list</code> role	Role must be either <code>directory</code> , <code>group</code> , <code>list</code> , <code>listbox</code> , <code>menu</code> , <code>menubar</code> , <code>tablist</code> , <code>toolbar</code> , or <code>tree</code>
<code>option^{p505}</code> element that is in a <code>list of options^{p499}</code> of a <code>select^{p498}</code> element with no <code>multiple^{p499}</code> attribute and with a <code>display size^{p499}</code> equal to 1	<code>option</code> role	Role must be either <code>option</code> , <code>menuitem</code> , <code>menuitemradio</code> , or <code>separator</code>
<code>output^{p516}</code> element	<code>status</code> role	No restrictions
<code>section^{p161}</code> element	<code>region</code> role	Role must be either <code>alert</code> , <code>alertdialog</code> , <code>application</code> , <code>contentinfo</code> , <code>dialog</code> , <code>document</code> , <code>log</code> , <code>main</code> , <code>marquee</code> , <code>region</code> , <code>search</code> , or <code>status</code>

Language feature	Default implicit ARIA semantic	Restrictions
<code>select</code> ^{p498} element with no <code>multiple</code> ^{p499} attribute and with a <code>display size</code> ^{p499} equal to 1	<code>listbox</code> role	Role must be either <code>listbox</code> or <code>menu</code>
<code>th</code> ^{p414} element that is not a <code>sorting-capable th element</code> ^{p423} or whose <code>column key ordinality</code> ^{p423} is not 1	<code>gridcell</code> role	Role must be either <code>columnheader</code> , <code>rowheader</code> , or <code>gridcell</code>
<code>ul</code> ^{p197} element	<code>list</code> role	Role must be either <code>directory</code> , <code>group</code> , <code>list</code> , <code>listbox</code> , <code>menu</code> , <code>menubar</code> , <code>tablist</code> , <code>toolbar</code> , or <code>tree</code>
<code>video</code> ^{p317} element	<code>No role</code> ^{p136}	If specified, role must be <code>application</code>
The body element ^{p106}	<code>document</code> role	Role must be either <code>document</code> or <code>application</code> Spec bugs: 12591 12592

The entry "**no role**", when used as a [strong native semantic](#), means that no role other than [presentation](#) can be used. When used as a [default implicit ARIA semantic](#), it means the user agent has no default mapping to ARIA roles. (However, it probably will have its own mappings to the accessibility layer.)

Conformance checkers are encouraged to phrase errors such that authors are encouraged to use more appropriate elements rather than remove accessibility annotations. For example, if an `a`^{p208} element is marked as having the `button` role, a conformance checker could say "Use a more appropriate element to represent a button, for example a `button`^{p495} element or an `input`^{p452} element" rather than "The `button` role cannot be used with `a`^{p208} elements".

Example

These features can be used to make accessibility tools render content to their users in more useful ways. For example, ASCII art, which is really an image, appears to be text, and in the absence of appropriate annotations would end up being rendered by screen readers as a very painful reading of lots of punctuation. Using the features described in this section, one can instead make the ATs skip the ASCII art and just read the caption:

```
<figure role="img" aria-labelledby="fish-caption">
  <pre>
    o           .`/
      '         /  (
      O   .-'`^`'-._       .')
      _/ (o)     ' . .'
      )         ))))    >< <
      ` \ |_\     _.' ' .
      ' -_ _ .-'   ' .
    jgs      ` \_ \
  </pre>
  <figcaption id="fish-caption">
    Joan G. Stark, "<cite>fish</cite>".
    October 1997. ASCII on electrons. 28x8.
  </figcaption>
</figure>
```

4 The elements of HTML

4.1 The root element

4.1.1 The `html` element

Spec bugs: [27319](#)

Categories^{p113}:

None.

Contexts in which this element can be used^{p113}:

As the root element of a document.

Wherever a subdocument fragment is allowed in a compound document.

Content model^{p113}:

A `head`^{p138} element followed by a `body`^{p157} element.

Tag omission in text/html^{p113}:

An `html`^{p137} element's `start tag`^{p944} can be omitted if the first thing inside the `html`^{p137} element is not a `comment`^{p952}.

An `html`^{p137} element's `end tag`^{p944} can be omitted if the `html`^{p137} element is not immediately followed by a `comment`^{p952}.

Content attributes^{p113}:

[Global attributes](#)^{p120}

`manifest`^{p137} — [Application cache manifest](#)^{p809}

DOM interface^{p113}:

IDL

```
interface HTMLHtmlElement : HTMLElement {  
    // also has obsolete members  
};
```

Spec bugs: [27539](#)

The `html`^{p137} element [represents](#)^{p111} the root of an HTML document.

Authors are encouraged to specify a `lang`^{p123} attribute on the root `html`^{p137} element, giving the document's language. This aids speech synthesis tools to determine what pronunciations to use, translation tools to determine what rules to use, and so forth.

The `manifest` attribute gives the address of the document's [application cache](#)^{p809} [manifest](#)^{p809}, if there is one. If the attribute is present, the attribute's value must be a [valid non-empty URL potentially surrounded by spaces](#)^{p82}.

The `manifest`^{p137} attribute only [has an effect](#)^{p822} during the early stages of document load. Changing the attribute dynamically thus has no effect (and thus, no DOM API is provided for this attribute).

Note For the purposes of [application cache selection](#)^{p822}, later `base`^{p140} elements cannot affect the [resolving of relative URLs](#)^{p82} in `manifest`^{p137} attributes, as the attributes are processed before those elements are seen.

Note The `window.applicationCache`^{p825} IDL attribute provides scripted access to the offline [application cache](#)^{p809} mechanism.

Example

The `html`^{p137} element in the following example declares that the document's language is English.

```
<!DOCTYPE html>  
<html lang="en">  
  <head>  
    <title>Swapping Songs</title>  
  </head>  
  <body>  
    <h1>Swapping Songs</h1>  
    <p>Tonight I swapped some of the songs I wrote with some friends, who  
      gave me some of the songs they wrote. I love sharing my music.</p>
```

```
</body>
</html>
```

4.2 Document metadata

4.2.1 The `head` element

Categories^{p113}:

None.

Contexts in which this element can be used^{p113}:

As the first element in an `html`^{p137} element.

Content model^{p113}:

If the document is an `iframe srcdoc` document^{p300} or if title information is available from a higher-level protocol: Zero or more elements of `metadata content`^{p115}, of which no more than one is a `title`^{p139} element and no more than one is a `base`^{p140} element.

Otherwise: One or more elements of `metadata content`^{p115}, of which exactly one is a `title`^{p139} element and no more than one is a `base`^{p140} element.

Tag omission in text/html^{p113}:

A `head`^{p138} element's `start tag`^{p944} can be omitted if the element is empty, or if the first thing inside the `head`^{p138} element is an element.

A `head`^{p138} element's `end tag`^{p944} can be omitted if the `head`^{p138} element is not immediately followed by a `space character`^{p58} or a `comment`^{p952}.

Content attributes^{p113}:

[Global attributes](#)^{p120}

DOM interface^{p113}:

```
IDL interface HTMLHeadElement : HTMLElement { };
```

The `head`^{p138} element [represents](#)^{p111} a collection of metadata for the `Document`^{p102}.

Example

The collection of metadata in a `head`^{p138} element can be large or small. Here is an example of a very short one:

```
<!doctype html>
<html>
  <head>
    <title>A document with a short head</title>
  </head>
  <body>
    ...
  </body>
</html>
```

Here is an example of a longer one:

```
<!DOCTYPE HTML>
<HTML>
  <HEAD>
    <META CHARSET="UTF-8">
    <BASE HREF="http://www.example.com/">
    <TITLE>An application with a long head</TITLE>
    <LINK REL="STYLESHEET" HREF="default.css">
    <LINK REL="STYLESHEET ALTERNATE" HREF="big.css" TITLE="Big Text">
    <SCRIPT SRC="support.js"></SCRIPT>
    <META NAME="APPLICATION-NAME" CONTENT="Long headed application">
  </HEAD>
  <BODY>
    ...
  </BODY>
</HTML>
```

Note The `title`^{p139} element is a required child in most situations, but when a higher-level protocol provides title information, e.g. in the Subject line of an e-mail when HTML is used as an e-mail authoring format, the `title`^{p139} element can be omitted.

4.2.2 The `title` element

Categories^{p113}:

[Metadata content](#)^{p115}.

Contexts in which this element can be used^{p113}:

In a `head`^{p138} element containing no other `title`^{p139} elements.

Content model^{p113}:

[Text](#)^{p116} that is not [inter-element whitespace](#)^{p113}.

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes](#)^{p120}

DOM interface^{p113}:

IDL

```
interface HTMLTitleElement : HTMLElement {
  attribute DOMString text;
};
```

The `title`^{p139} element [represents](#)^{p111} the document's title or name. Authors should use titles that identify their documents even when they are used out of context, for example in a user's history or bookmarks, or in search results. The document's title is often different from its first heading, since the first heading does not have to stand alone when taken out of context.

There must be no more than one `title`^{p139} element per document.

Note If it's reasonable for the `Document`^{b102} to have no title, then the `title`^{b139} element is probably not required. See the `head`^{p138} element's content model for a description of when the element is required.

Note

`title.text`^{p139} [= value]

Returns the contents of the element, ignoring child nodes that aren't `Text`^{p51} nodes.

Can be set, to replace the element's children with the given value.

The IDL attribute `text` must return a concatenation of the contents of all the `Text`^{p51} nodes that are children of the `title`^{p139} element (ignoring any other nodes such as comments or elements), in [tree order](#)^{p42}. On setting, it must act the same way as the `textContent`^{p51} IDL attribute.

Example

Here are some examples of appropriate titles, contrasted with the top-level headings that might be used on those same pages.

```
<title>Introduction to The Mating Rituals of Bees</title>
...
<h1>Introduction</h1>
<p>This companion guide to the highly successful
<cite>Introduction to Medieval Bee-Keeping</cite> book is...
```

The next page might be a part of the same site. Note how the title describes the subject matter unambiguously, while the first heading assumes the reader knows what the context is and therefore won't wonder if the dances are Salsa or Waltz:

```
<title>Dances used during bee mating rituals</title>
...
<h1>The Dances</h1>
```

The string to use as the document's title is given by the [document.title](#) IDL attribute.

User agents should use the document's title when referring to the document in their user interface. When the contents of a [title](#) element are used in this way, [the directionality](#) of that [title](#) element should be used to set the directionality of the document's title in the user interface.

4.2.3 The `base` element

Categories^{p113}:

[Metadata content](#)^{p115}.

Contexts in which this element can be used^{p113}:

In a [head](#)^{p138} element containing no other [base](#)^{p140} elements.

Content model^{p113}:

[Nothing](#)^{p114}.

Tag omission in text/html^{p113}:

No [end tag](#)^{p944}.

Content attributes^{p113}:

[Global attributes](#)^{p120}

[href](#)^{p140} — [Document base URL](#)^{p82}

[target](#)^{p140} — Default [browsing context](#)^{p762} for [hyperlink](#)^{p245} [navigation](#)^{p791} and [form submission](#)^{p557}

DOM interface^{p113}:

```
IDL interface HTMLBaseElement : HTMLElement {
    attribute DOMString href;
    attribute DOMString target;
};
```

The [base](#)^{p140} element allows authors to specify the [document base URL](#)^{p82} for the purposes of [resolving relative URLs](#)^{p82}, and the name of the default [browsing context](#)^{p762} for the purposes of [following hyperlinks](#)^{p246}. The element does not [represent](#)^{p111} any content beyond this information.

There must be no more than one [base](#)^{p140} element per document.

A [base](#)^{p140} element must have either an [href](#)^{p140} attribute, a [target](#)^{p140} attribute, or both.

The [href](#) content attribute, if specified, must contain a [valid URL potentially surrounded by spaces](#)^{p82}.

A [base](#)^{p140} element, if it has an [href](#)^{p140} attribute, must come before any other elements in the tree that have attributes defined as taking [URLs](#)^{p48}, except the [html](#)^{p137} element (its [manifest](#)^{p137} attribute isn't affected by [base](#)^{p140} elements).

Note If there are multiple [base](#)^{p140} elements with [href](#)^{p140} attributes, all but the first are ignored.

The [target](#) attribute, if specified, must contain a [valid browsing context name or keyword](#)^{p766}, which specifies which [browsing context](#)^{p762} is to be used as the default when [hyperlinks](#)^{p245} and [forms](#)^{p447} in the [Document](#)^{p102} cause [navigation](#)^{p791}.

A [base](#)^{p140} element, if it has a [target](#)^{p140} attribute, must come before any elements in the tree that represent [hyperlinks](#)^{p245}.

Note If there are multiple [base](#)^{p140} elements with [target](#)^{p140} attributes, all but the first are ignored.

A [base](#)^{p140} element that is the first [base](#)^{p140} element with an [href](#)^{p140} content attribute in a particular [Document](#)^{p102} has a **frozen base URL**. The [frozen base URL](#)^{p140} must be [immediately](#)^{p41} [set](#)^{p141} whenever any of the following situations occur:

- The [base](#)^{p140} element becomes the first [base](#)^{p140} element in [tree order](#)^{p42} with an [href](#)^{p140} content attribute in its [Document](#)^{p102}.

- The `base`^{p140} element is the first `base`^{p140} element in `tree order`^{p42} with an `href`^{p140} content attribute in its `Document`^{p102}, and its `href`^{p140} content attribute is changed.

To set the frozen base URL, `resolve`^{p82} the value of the element's `href`^{p140} content attribute relative to the `Document`^{p102}'s `fallback base URL`^{p82}; if this is successful, set the `frozen base URL`^{p140} to the `resulting absolute URL`^{p83}, otherwise, set the `frozen base URL`^{p140} to the `fallback base URL`^{p82}.

The `href` IDL attribute, on getting, must return the result of running the following algorithm:

- If the `base`^{p140} element has no `href`^{p140} content attribute, then return the `document base URL`^{p82} and abort these steps.
- Let `fallback base url` be the `Document`^{p102}'s `fallback base URL`^{p82}.
- Let `url` be the value of the `href`^{p140} attribute of the `base`^{p140} element.
- `Resolve`^{p82} `url` relative to `fallback base url` (thus, the `base`^{p140} `href`^{p140} attribute isn't affected by `xml:base`^{p125} attributes or `base`^{p140} elements).
- If the previous step was successful, return the resulting `absolute URL`^{p48} and abort these steps.
- Otherwise, return the empty string.

The `href`^{p141} IDL attribute, on setting, must set the `href`^{p140} content attribute to the given new value.

The `target` IDL attribute must `reflect`^{p88} the content attribute of the same name.

Example

In this example, a `base`^{p140} element is used to set the `document base URL`^{p82}:

```
<!DOCTYPE html>
<html>
  <head>
    <title>This is an example for the &lt;base&gt; element</title>
    <base href="http://www.example.com/news/index.html">
  </head>
  <body>
    <p>Visit the <a href="archives.html">archives</a>.</p>
  </body>
</html>
```

The link in the above example would be a link to "http://www.example.com/news/archives.html".

4.2.4 The `link` element

Spec bugs: [17999](#), [20166](#), [21622](#)

Categories^{p113}:

[Metadata content](#)^{p115}.

If the `itemprop`^{p692} attribute is present: [flow content](#)^{p115}.

If the `itemprop`^{p692} attribute is present: [phrasing content](#)^{p116}.

Contexts in which this element can be used^{p113}:

Where [metadata content](#)^{p115} is expected.

In a `noscript`^{p602} element that is a child of a `head`^{p138} element.

If the `itemprop`^{p692} attribute is present: where [phrasing content](#)^{p116} is expected.

Content model^{p113}:

[Nothing](#)^{p114}.

Tag omission in text/html^{p113}:

No [end tag](#)^{p944}.

Content attributes^{p113}:

[Global attributes](#)^{p120}

`href`^{p142} — Address of the [hyperlink](#)^{p245}
`crossorigin`^{p142} — How the element handles crossorigin requests
`rel`^{p142} — Relationship between the document containing the hyperlink and the destination resource
`media`^{p143} — Applicable media
`hreflang`^{p144} — Language of the linked resource
`type`^{p144} — Hint for the type of the referenced resource
`sizes`^{p253} — Sizes of the icons (for `rel`=`"icon"`)
Also, the `title`^{p144} attribute [has special semantics](#)^{p144} on this element: Title of the link; alternative style sheet set name.

DOM interface^{p113}:

```

IDL
interface HTMLLinkElement : HTMLElement {
    attribute DOMString href;
    attribute DOMString? crossOrigin;
    attribute DOMString rel;
    readonly attribute DOMTokenList relList;
    attribute DOMString media;
    attribute DOMString hreflang;
    attribute DOMString type;
    [PutForwards=value] readonly attribute DOMSettableTokenList sizes;

    // also has obsolete members
};

HTMLLinkElement implements LinkStyle;

```

The [link](#)^{p141} element allows authors to link their document to other resources.

The destination of the link(s) is given by the `href` attribute, which must be present and must contain a [valid non-empty URL potentially surrounded by spaces](#)^{p82}. If the `href`^{p142} attribute is absent, then the element does not define a link.

A [link](#)^{p141} element must have either a `rel`^{p142} attribute or an `itemprop`^{p692} attribute, but not both.

Note *If the `rel`^{p142} attribute is used, the element is restricted to the [head](#)^{p138} element. When used with the `itemprop`^{p692} attribute, the element can be used both in the [head](#)^{p138} element and in the [body](#)^{p157} of the page, subject to the constraints of the microdata model.*

The types of link indicated (the relationships) are given by the value of the `rel` attribute, which, if present, must have a value that is a [set of space-separated tokens](#)^{p80}. The [allowed keywords and their meanings](#)^{p250} are defined in a later section. If the `rel`^{p142} attribute is absent, has no keywords, or if none of the keywords used are allowed according to the definitions in this specification, then the element does not create any links.

Two categories of links can be created using the [link](#)^{p141} element: [Links to external resources](#)^{p245} and [hyperlinks](#)^{p245}. The [link types section](#)^{p250} defines whether a particular link type is an external resource or a hyperlink. One [link](#)^{p141} element can create multiple links (of which some might be external resource links and some might be hyperlinks); exactly which and how many links are created depends on the keywords given in the `rel`^{p142} attribute. User agents must process the links on a per-link basis, not a per-element basis.

Note *Each link created for a [link](#)^{p141} element is handled separately. For instance, if there are two [link](#)^{p141} elements with `rel="stylesheet"`, they each count as a separate external resource, and each is affected by its own attributes independently. Similarly, if a single [link](#)^{p141} element has a `rel`^{p142} attribute with the value `next stylesheet`, it creates both a [hyperlink](#)^{p245} (for the `next`^{p259} keyword) and an [external resource link](#)^{p245} (for the `stylesheet`^{p256} keyword), and they are affected by other attributes (such as `media`^{p143} or `title`^{p144}) differently.*

Example

For example, the following [link](#)^{p141} element creates two hyperlinks (to the same page):

```
<link rel="author license" href="/about">
```

The two links created by this element are one whose semantic is that the target page has information about the current page's author, and one whose semantic is that the target page has information regarding the license under which the current page is provided.

The `crossorigin` attribute is a [CORS settings attribute](#)^{p87}. It is intended for use with external resource links.

The exact behaviour for links to external resources depends on the exact relationship, as defined for the relevant link type. Some of the attributes control whether or not the external resource is to be applied (as defined below).

For external resources that are represented in the DOM (for example, style sheets), the DOM representation must be made available (modulo cross-origin restrictions) even if the resource is not applied. To **obtain the resource**, the user agent must run the following steps:

1. If the [href^{p142}](#) attribute's value is the empty string, then abort these steps.
2. [Resolve^{p82}](#) the [URL^{p48}](#) given by the [href^{p142}](#) attribute, relative to the element.
3. If the previous step fails, then abort these steps.
4. Do a [potentially CORS-enabled fetch^{p87}](#) of the resulting [absolute URL^{p48}](#), with the *mode* being the current state of the element's [crossorigin^{p142}](#) content attribute, the *origin* being the [origin^{p776}](#) of the [link^{p141}](#) element's [node document](#), and the *default origin behaviour* set to *taint*.

The resource obtained in this fashion can be either [CORS-same-origin^{p87}](#) or [CORS-cross-origin^{p87}](#).

User agents may opt to only try to obtain such resources when they are needed, instead of proactively [fetching^{p84}](#) all the external resources that are not applied.

The semantics of the protocol used (e.g. HTTP) must be followed when fetching external resources. (For example, redirects will be followed and 404 responses will cause the external resource to not be applied.)

Once the attempts to obtain the resource and its [critical subresources^{p42}](#) are complete, the user agent must, if the loads were successful, [queue a task^{p835}](#) to [fire a simple event^{p846}](#) named [load^{p1144}](#) at the [link^{p141}](#) element, or, if the resource or one of its [critical subresources^{p42}](#) failed to completely load for any reason (e.g. DNS error, HTTP 404 response, a connection being prematurely closed, unsupported Content-Type), [queue a task^{p835}](#) to [fire a simple event^{p846}](#) named [error^{p1144}](#) at the [link^{p141}](#) element. Non-network errors in processing the resource or its subresources (e.g. CSS parse errors, PNG decoding errors) are not failures for the purposes of this paragraph.

The [task source^{p835}](#) for these [tasks^{p834}](#) is the [DOM manipulation task source^{p838}](#).

The element must [delay the load event^{p1033}](#) of the element's [node document](#) until all the attempts to obtain the resource and its [critical subresources^{p42}](#) are complete. (Resources that the user agent has not yet attempted to obtain, e.g. because it is waiting for the resource to be needed, do not [delay the load event^{p1033}](#).)

Interactive user agents may provide users with a means to [follow the hyperlinks^{p246}](#) created using the [link^{p141}](#) element, somewhere within their user interface. The exact interface is not defined by this specification, but it could include the following information (obtained from the element's attributes, again as defined below), in some form or another (possibly simplified), for each hyperlink created with each [link^{p141}](#) element in the document:

- The relationship between this document and the resource (given by the [rel^{p142}](#) attribute).
- The title of the resource (given by the [title^{p144}](#) attribute).
- The address of the resource (given by the [href^{p142}](#) attribute).
- The language of the resource (given by the [hreflang^{p144}](#) attribute).
- The optimum media for the resource (given by the [media^{p143}](#) attribute).

User agents could also include other information, such as the type of the resource (as given by the [type^{p144}](#) attribute).

Note *Hyperlinks created with the [link^{p141}](#) element and its [rel^{p142}](#) attribute apply to the whole page. This contrasts with the [rel^{p246}](#) attribute of [a^{p208}](#) and [area^{p390}](#) elements, which indicates the type of a link whose context is given by the link's location within the document.*

The [media](#) attribute says which media the resource applies to. The value must be a [valid media query list^{p81}](#).

If the link is a [hyperlink^{p245}](#) then the [media^{p143}](#) attribute is purely advisory, and describes for which media the document in question was designed.

However, if the link is an [external resource link^{p245}](#), then the [media^{p143}](#) attribute is prescriptive. The user agent must apply the external resource when the [media^{p143}](#) attribute's value [matches the environment^{p81}](#) and the other relevant conditions apply, and must not apply it otherwise.

Note The external resource might have further restrictions defined within that limit its applicability. For example, a CSS style sheet might have some `@media` blocks. This specification does not override such further restrictions or requirements.

The default, if the `media`^{p143} attribute is omitted, is "all", meaning that by default links apply to all media.

The `hreflang` attribute on the `link`^{p141} element has the same semantics as the [hreflang attribute on a and area elements](#)^{p246}.

The `type` attribute gives the [MIME type](#)^{p42} of the linked resource. It is purely advisory. The value must be a [valid MIME type](#)^{p42}.

For [external resource links](#)^{p245}, the `type`^{p144} attribute is used as a hint to user agents so that they can avoid fetching resources they do not support. If the attribute is present, then the user agent must assume that the resource is of the given type (even if that is not a [valid MIME type](#)^{p42}, e.g. the empty string). If the attribute is omitted, but the external resource link type has a default type defined, then the user agent must assume that the resource is of that type. If the UA does not support the given [MIME type](#)^{p42} for the given link relationship, then the UA should not [obtain](#)^{p143} the resource; if the UA does support the given [MIME type](#)^{p42} for the given link relationship, then the UA should [obtain](#)^{p143} the resource at the appropriate time as specified for the [external resource link](#)^{p245}'s particular type. If the attribute is omitted, and the external resource link type does not have a default type defined, but the user agent would [obtain](#)^{p143} the resource if the type was known and supported, then the user agent should [obtain](#)^{p143} the resource under the assumption that it will be supported.

User agents must not consider the `type`^{p144} attribute authoritative — upon fetching the resource, user agents must not use the `type`^{p144} attribute to determine its actual type. Only the actual type (as defined in the next paragraph) is used to determine whether to *apply* the resource, not the aforementioned assumed type.

If the external resource link type defines rules for processing the resource's [Content-Type metadata](#)^{p86}, then those rules apply. Otherwise, if the resource is expected to be an image, user agents may apply the [image sniffing rules](#), with the [official type](#) being the type determined from the resource's [Content-Type metadata](#)^{p86}, and use the resulting sniffed type of the resource as if it was the actual type. Otherwise, if neither of these conditions apply or if the user agent opts not to apply the image sniffing rules, then the user agent must use the resource's [Content-Type metadata](#)^{p86} to determine the type of the resource. If there is no type metadata, but the external resource link type has a default type defined, then the user agent must assume that the resource is of that type.

Note The `stylesheet`^{p256} link type defines rules for processing the resource's [Content-Type metadata](#)^{p86}.

Once the user agent has established the type of the resource, the user agent must apply the resource if it is of a supported type and the other relevant conditions apply, and must ignore the resource otherwise.

Example

If a document contains style sheet links labeled as follows:

```
<link rel="stylesheet" href="A" type="text/plain">
<link rel="stylesheet" href="B" type="text/css">
<link rel="stylesheet" href="C">
```

...then a compliant UA that supported only CSS style sheets would fetch the B and C files, and skip the A file (since `text/plain` is not the [MIME type](#)^{p42} for CSS style sheets).

For files B and C, it would then check the actual types returned by the server. For those that are sent as `text/css`^{p146}, it would apply the styles, but for those labeled as `text/plain`, or any other type, it would not.

If one of the two files was returned without a [Content-Type](#)^{p86} metadata, or with a syntactically incorrect type like `Content-Type: "null"`, then the default type for `stylesheet`^{p256} links would kick in. Since that default type is `text/css`, the style sheet would nonetheless be applied.

The `title` attribute gives the title of the link. With one exception, it is purely advisory. The value is text. The exception is for style sheet links, where the `title`^{p144} attribute defines [alternative style sheet sets](#)^{p53}.

Note The `title`^{p144} attribute on `link`^{p141} elements differs from the global `title`^{p122} attribute of most other elements in that a link without a title does not inherit the title of the parent element: it merely has no title.

The `sizes`^{p253} attribute is used with the `icon`^{p253} link type. The attribute must not be specified on `link`^{p141} elements that do not have a `rel`^{p142} attribute that specifies the `icon`^{p253} keyword.

The [activation behaviour](#)^{p725} of `link`^{p141} elements that create [hyperlinks](#)^{p245} is to run the following steps:

1. If the [link](#)^{p141} element's [node document](#) is not [fully active](#)^{p763}, then abort these steps.
2. Follow the [hyperlink](#)^{p246} created by the [link](#)^{p141} element.

HTTP [Link:](#)^{p49} headers, if supported, must be assumed to come before any links in the document, in the order that they were given in the HTTP message. These headers are to be processed according to the rules given in the relevant specifications. [HTTP]^{p1150} [WEBLINK]^{p1154}

Note *Registration of relation types in HTTP Link: headers is distinct from [HTML link types](#)^{p250}, and thus their semantics can be different from same-named HTML types.*

The IDL attributes `href`, `rel`, `media`, `hreflang`, `type`, and `sizes` each must [reflect](#)^{p88} the respective content attributes of the same name.

The `crossOrigin` IDL attribute must [reflect](#)^{p88} the `crossoverorigin`^{p142} content attribute.

The IDL attribute `relList` must [reflect](#)^{p88} the `rel`^{p142} content attribute.

The [LinkStyle](#)^{p53} interface is also implemented by this element. [CSSOM]^{p1149}

Example

Here, a set of [link](#)^{p141} elements provide some style sheets:

```
<!-- a persistent style sheet -->
<link rel="stylesheet" href="default.css">

<!-- the preferred alternate style sheet -->
<link rel="stylesheet" href="green.css" title="Green styles">

<!-- some alternate style sheets -->
<link rel="alternate stylesheet" href="contrast.css" title="High contrast">
<link rel="alternate stylesheet" href="big.css" title="Big fonts">
<link rel="alternate stylesheet" href="wide.css" title="Wide screen">
```

Example

The following example shows how you can specify versions of the page that use alternative formats, are aimed at other languages, and that are intended for other media:

```
<link rel=alternate href="/en/html" hreflang=en type=text/html title="English HTML">
<link rel=alternate href="/fr/html" hreflang=fr type=text/html title="French HTML">
<link rel=alternate href="/en/html/print" hreflang=en type=text/html media=print title="English HTML (for printing)">
<link rel=alternate href="/fr/html/print" hreflang=fr type=text/html media=print title="French HTML (for printing)">
<link rel=alternate href="/en/pdf" hreflang=en type=application/pdf title="English PDF">
<link rel=alternate href="/fr/pdf" hreflang=fr type=application/pdf title="French PDF">
```

4.2.5 The `meta` element

Categories^{p113}:

[Metadata content](#)^{p115}.

If the `itemprop`^{p692} attribute is present: [flow content](#)^{p115}.

If the `itemprop`^{p692} attribute is present: [phrasing content](#)^{p116}.

Contexts in which this element can be used^{p113}:

If the `charset`^{p146} attribute is present, or if the element's `http-equiv`^{p149} attribute is in the [Encoding declaration state](#)^{p150}: in a `head`^{p138} element.

If the `http-equiv`^{p149} attribute is present but not in the [Encoding declaration state](#)^{p150}: in a `head`^{p138} element.

If the `http-equiv`^{p149} attribute is present but not in the [Encoding declaration state](#)^{p150}: in a `noscript`^{p602} element that is a child of a `head`^{p138} element.

If the `name`^{p146} attribute is present: where [metadata content](#)^{p115} is expected.

If the `itemprop`^{p692} attribute is present: where [metadata content](#)^{p115} is expected.

If the `itemprop`^{p692} attribute is present: where [phrasing content](#)^{p116} is expected.

Content model^{p113}:

[Nothing](#)^{p114}.

Tag omission in text/html^{p113}:

No [end tag](#)^{p944}.

Content attributes^{p113}:

[Global attributes](#)^{p120}

`name`^{p146} — Metadata name

`http-equiv`^{p149} — Pragma directive

`content`^{p146} — Value of the element

`charset`^{p146} — [Character encoding declaration](#)^{p153}

DOM interface^{p113}:

```
IDL interface HTMLMetaElement : HTMLElement {
    attribute DOMString name;
    attribute DOMString httpEquiv;
    attribute DOMString content;

    // also has obsolete members
};
```

The `meta`^{p145} element [represents](#)^{p111} various kinds of metadata that cannot be expressed using the `title`^{b139}, `base`^{b140}, `link`^{b141}, `style`^{p154}, and `script`^{b591} elements.

The `meta`^{p145} element can represent document-level metadata with the `name`^{p146} attribute, pragma directives with the `http-equiv`^{p149} attribute, and the file's [character encoding declaration](#)^{p153} when an HTML document is serialised to string form (e.g. for transmission over the network or for disk storage) with the `charset`^{p146} attribute.

Exactly one of the `name`^{p146}, `http-equiv`^{p149}, `charset`^{p146}, and `itemprop`^{p692} attributes must be specified.

If either `name`^{p146}, `http-equiv`^{p149}, or `itemprop`^{p692} is specified, then the `content`^{p146} attribute must also be specified. Otherwise, it must be omitted.

The `charset` attribute specifies the character encoding used by the document. This is a [character encoding declaration](#)^{p153}. If the attribute is present in an [XML document](#)^{b51}, its value must be an [ASCII case-insensitive](#)^{p58} match for the string "UTF-8" (and the document is therefore forced to use UTF-8 as its encoding).

Note The `charset`^{p146} attribute on the `meta`^{p145} element has no effect in XML documents, and is only allowed in order to facilitate migration to and from XHTML.

There must not be more than one `meta`^{p145} element with a `charset`^{p146} attribute per document.

The `content` attribute gives the value of the document metadata or pragma directive when the element is used for those purposes. The allowed values depend on the exact context, as described in subsequent sections of this specification.

If a `meta`^{p145} element has a `name` attribute, it sets document metadata. Document metadata is expressed in terms of name-value pairs, the `name`^{p146} attribute on the `meta`^{p145} element giving the name, and the `content`^{p146} attribute on the same element giving the value. The name specifies what aspect of metadata is being set; valid names and the meaning of their values are described in the following sections. If a `meta`^{p145} element has no `content`^{p146} attribute, then the value part of the metadata name-value pair is the empty string.

The `name` and `content` IDL attributes must [reflect](#)^{p88} the respective content attributes of the same name. The IDL attribute `httpEquiv` must [reflect](#)^{p88} the content attribute `http-equiv`^{p149}.

4.2.5.1 Standard metadata names

This specification defines a few names for the `namep146` attribute of the `metap145` element.

Names are case-insensitive, and must be compared in an [ASCII case-insensitive^{p58}](#) manner.

`application-name`

The value must be a short free-form string giving the name of the Web application that the page represents. If the page is not a Web application, the `application-namep147` metadata name must not be used. Translations of the Web application's name may be given, using the `langp123` attribute to specify the language of each name.

There must not be more than one `metap145` element with a given `languagep123` and with its `namep146` attribute set to the value `application-namep147` per document.

User agents may use the application name in UI in preference to the page's `titlep139`, since the title might include status messages and the like relevant to the status of the page at a particular moment in time instead of just being the name of the application.

To find the application name to use given an ordered list of languages (e.g. British English, American English, and English), user agents must run the following steps:

1. Let `languages` be the list of languages.
 2. Let `default language` be the `languagep123` of the `Documentp102`'s `root elementp42`, if any, and if that language is not unknown.
 3. If there is a `default language`, and if it is not the same language as any of the languages in `languages`, append it to `languages`.
 4. Let `winning language` be the first language in `languages` for which there is a `metap145` element in the `Documentp102` that has its `namep146` attribute set to the value `application-namep147` and whose `languagep123` is the language in question.
- If none of the languages have such a `metap145` element, then abort these steps; there's no given application name.
5. Return the value of the `contentp146` attribute of the first `metap145` element in the `Documentp102` in `tree orderp42` that has its `namep146` attribute set to the value `application-namep147` and whose `languagep123` is `winning language`.

Note This algorithm would be used by a browser when it needs a name for the page, for instance, to label a bookmark. The languages it would provide to the algorithm would be the user's preferred languages.

`author`

The value must be a free-form string giving the name of one of the page's authors.

`description`

The value must be a free-form string that describes the page. The value must be appropriate for use in a directory of pages, e.g. in a search engine. There must not be more than one `metap145` element with its `namep146` attribute set to the value `descriptionp147` per document.

`generator`

The value must be a free-form string that identifies one of the software packages used to generate the document. This value must not be used on pages whose markup is not generated by software, e.g. pages whose markup was written by a user in a text editor.

Example Here is what a tool called "Frontweaver" could include in its output, in the page's `headp138` element, to identify itself as the tool used to generate the page:

```
<meta name=generator content="Frontweaver 8.2">
```

`keywords`

The value must be a [set of comma-separated tokens^{p80}](#), each of which is a keyword relevant to the page.

Example This page about typefaces on British motorways uses a `metap145` element to specify some keywords that users might use to look for the page:

```
<!DOCTYPE HTML>
<html>
  <head>
    <title>Typefaces on UK motorways</title>
```

```
<meta name="keywords" content="british,type face,font,fonts,highway,highways">
</head>
<body>
  ...

```

Note Many search engines do not consider such keywords, because this feature has historically been used unreliably and even misleadingly as a way to spam search engine results in a way that is not helpful for users.

To obtain the list of keywords that the author has specified as applicable to the page, the user agent must run the following steps:

1. Let *keywords* be an empty list.
2. For each `metap145` element with a `namep146` attribute and a `contentp146` attribute and whose `namep146` attribute's value is `keywordsp147`, run the following substeps:
 1. [Split the value of the element's content attribute on commas^{p81}](#).
 2. Add the resulting tokens, if any, to *keywords*.
3. Remove any duplicates from *keywords*.
4. Return *keywords*. This is the list of keywords that the author has specified as applicable to the page.

User agents should not use this information when there is insufficient confidence in the reliability of the value.

Example For instance, it would be reasonable for a content management system to use the keyword information of pages within the system to populate the index of a site-specific search engine, but a large-scale content aggregator that used this information would likely find that certain users would try to game its ranking mechanism through the use of inappropriate keywords.

4.2.5.2 Other metadata names

Extensions to the predefined set of metadata names may be registered in the [WHATWG Wiki MetaExtensions page](#). [\[WHATWGWiki\]^{p1154}](#)

Anyone is free to edit the WHATWG Wiki MetaExtensions page at any time to add a type. These new names must be specified with the following information:

Keyword

The actual name being defined. The name should not be confusingly similar to any other defined name (e.g. differing only in case).

Brief description

A short non-normative description of what the metadata name's meaning is, including the format the value is required to be in.

Specification

A link to a more detailed description of the metadata name's semantics and requirements. It could be another page on the Wiki, or a link to an external page.

Synonyms

A list of other names that have exactly the same processing requirements. Authors should not use the names defined to be synonyms, they are only intended to allow user agents to support legacy content. Anyone may remove synonyms that are not used in practice; only names that need to be processed as synonyms for compatibility with legacy content are to be registered in this way.

Status

One of the following:

Proposed

The name has not received wide peer review and approval. Someone has proposed it and is, or soon will be, using it.

Ratified

The name has received wide peer review and approval. It has a specification that unambiguously defines how to handle pages that use the name, including when they use it in incorrect ways.

Discontinued

The metadata name has received wide peer review and it has been found wanting. Existing pages are using this metadata name, but new pages should avoid it. The "brief description" and "specification" entries will give details of what authors should use instead, if anything.

If a metadata name is found to be redundant with existing values, it should be removed and listed as a synonym for the existing value.

If a metadata name is registered in the "proposed" state for a period of a month or more without being used or specified, then it may be removed from the registry.

If a metadata name is added with the "proposed" status and found to be redundant with existing values, it should be removed and listed as a synonym for the existing value. If a metadata name is added with the "proposed" status and found to be harmful, then it should be changed to "discontinued" status.

Anyone can change the status at any time, but should only do so in accordance with the definitions above.

Conformance checkers must use the information given on the WHATWG Wiki MetaExtensions page to establish if a value is allowed or not: values defined in this specification or marked as "proposed" or "ratified" must be accepted, whereas values marked as "discontinued" or not listed in either this specification or on the aforementioned page must be rejected as invalid. Conformance checkers may cache this information (e.g. for performance reasons or to avoid the use of unreliable network connectivity).

When an author uses a new metadata name not defined by either this specification or the Wiki page, conformance checkers should offer to add the value to the Wiki, with the details described above, with the "proposed" status.

Metadata names whose values are to be [URLs^{p48}](#) must not be proposed or accepted. Links must be represented using the [link^{p141}](#) element, not the [meta^{p145}](#) element.

4.2.5.3 Pragma directives

When the [http-equiv](#) attribute is specified on a [meta^{p145}](#) element, the element is a pragma directive.

The [http-equiv^{p149}](#) attribute is an [enumerated attribute^{p60}](#). The following table lists the keywords defined for this attribute. The states given in the first cell of the rows with keywords give the states to which those keywords map. Some of the keywords are non-conforming, as noted in the last column.

State	Keyword	Notes
Content Language^{p149}	content-language	Non-conforming
Encoding declaration^{p150}	content-type	
Default style^{p150}	default-style	
Refresh^{p150}	refresh	
Cookie setter^{p152}	set-cookie	Non-conforming
X-UA-Compatible^{p152}	x-ua-compatible	

When a [meta^{p145}](#) element is [inserted into the document^{p42}](#), if its [http-equiv^{p149}](#) attribute is present and represents one of the above states, then the user agent must run the algorithm appropriate for that state, as described in the following list:

Content language state ([http-equiv="content-language"](#))

Note This feature is non-conforming. Authors are encouraged to use the [lang^{p123}](#) attribute instead.

This pragma sets the [pragma-set default language](#). Until such a pragma is successfully processed, there is no [pragma-set default language^{b149}](#).

1. If the [meta^{p145}](#) element has no [content^{p146}](#) attribute, then abort these steps.
2. If the element's [content^{p146}](#) attribute contains a U+002C COMMA character (,) then abort these steps.
3. Let *input* be the value of the element's [content^{p146}](#) attribute.
4. Let *position* point at the first character of *input*.
5. [Skip whitespace^{p59}](#).

6. [Collect a sequence of characters](#)^{p59} that are not [space characters](#)^{p58}.
7. Let *candidate* be the string that resulted from the previous step.
8. If *candidate* is the empty string, abort these steps.
9. Set the [pragma-set default language](#)^{p149} to *candidate*.

Note *If the value consists of multiple space-separated tokens, tokens after the first are ignored.*

Note *This pragma is almost, but not quite, entirely unlike the HTTP [Content-Language](#)^{p49} header of the same name. [[HTTP](#)]^{p150}*

Encoding declaration state (`http-equiv="content-type"`)

The [Encoding declaration state](#)^{p150} is just an alternative form of setting the [charset](#)^{p146} attribute: it is a [character encoding declaration](#)^{p153}. This state's user agent requirements are all handled by the parsing section of the specification.

For [meta](#)^{p145} elements with an [http-equiv](#)^{p149} attribute in the [Encoding declaration state](#)^{p150}, the [content](#)^{p146} attribute must have a value that is an [ASCII case-insensitive](#)^{p58} match for a string that consists of: the literal string "text/html;", optionally followed by any number of [space characters](#)^{p58}, followed by the literal string "charset=", followed by one of the [labels](#)^{p44} of the [character encoding](#)^{p44} of the [character encoding declaration](#)^{p153}.

A document must not contain both a [meta](#)^{p145} element with an [http-equiv](#)^{p149} attribute in the [Encoding declaration state](#)^{p150} and a [meta](#)^{p145} element with the [charset](#)^{p146} attribute present.

The [Encoding declaration state](#)^{p150} may be used in [HTML documents](#)^{p51}, but elements with an [http-equiv](#)^{p149} attribute in that state must not be used in [XML documents](#)^{p51}.

Default style state (`http-equiv="default-style"`)

This pragma sets the name of the default [alternative style sheet set](#)^{p53}.

1. If the [meta](#)^{p145} element has no [content](#)^{p146} attribute, or if that attribute's value is the empty string, then abort these steps.
2. Set the [preferred style sheet set](#)^{p53} to the value of the element's [content](#)^{p146} attribute. [[CSSOM](#)]^{p1149}

Refresh state (`http-equiv="refresh"`)

This pragma acts as timed redirect.

1. If another [meta](#)^{p145} element with an [http-equiv](#)^{p149} attribute in the [Refresh state](#)^{p150} has already been successfully processed (i.e. when it was inserted the user agent processed it and reached the last step of this list of steps), then abort these steps.
2. If the [meta](#)^{p145} element has no [content](#)^{p146} attribute, or if that attribute's value is the empty string, then abort these steps.
3. Let *input* be the value of the element's [content](#)^{p146} attribute.
4. Let *position* point at the first character of *input*.
5. [Skip whitespace](#)^{p59}.
6. [Collect a sequence of characters](#)^{p59} that are [ASCII digits](#)^{p58}, and parse the resulting string using the [rules for parsing non-negative integers](#)^{p61}. If the sequence of characters collected is the empty string, then no number will have been parsed; abort these steps. Otherwise, let *time* be the parsed number.
7. [Collect a sequence of characters](#)^{p59} that are [ASCII digits](#)^{p58} and U+002E FULL STOP characters (.). Ignore any collected characters.
8. [Skip whitespace](#)^{p59}.
9. Let *url* be the address of the current page.
10. If the character in *input* pointed to by *position* is a U+003B SEMICOLON character (;) or a U+002C COMMA character (,), then advance *position* to the next character. Otherwise, jump to the last step.
11. [Skip whitespace](#)^{p59}.
12. If the character in *input* pointed to by *position* is a U+0055 LATIN CAPITAL LETTER U character (U) or a U+0075 LATIN SMALL LETTER U character (u), then advance *position* to the next character. Otherwise, jump to the last step.

13. If the character in *input* pointed to by *position* is a U+0052 LATIN CAPITAL LETTER R character (R) or a U+0072 LATIN SMALL LETTER R character (r), then advance *position* to the next character. Otherwise, jump to the last step.
14. If the character in *input* pointed to by *position* is s U+004C LATIN CAPITAL LETTER L character (L) or a U+006C LATIN SMALL LETTER L character (l), then advance *position* to the next character. Otherwise, jump to the last step.
15. [Skip whitespace^{p59}](#).
16. If the character in *input* pointed to by *position* is a U+003D EQUALS SIGN (=), then advance *position* to the next character. Otherwise, jump to the last step.
17. [Skip whitespace^{p59}](#).
18. If the character in *input* pointed to by *position* is either a U+0027 APOSTROPHE character ('') or U+0022 QUOTATION MARK character (""), then let *quote* be that character, and advance *position* to the next character. Otherwise, let *quote* be the empty string.
19. Let *url* be equal to the substring of *input* from the character at *position* to the end of the string.
20. If *quote* is not the empty string, and there is a character in *url* equal to *quote*, then truncate *url* at that character, so that it and all subsequent characters are removed.
21. Strip any trailing [space characters^{p58}](#) from the end of *url*.
22. Strip any U+0009 CHARACTER TABULATION (tab), U+000A LINE FEED (LF), and U+000D CARRIAGE RETURN (CR) characters from *url*.
23. [Resolve^{p82}](#) the *url* value to an [absolute URL^{p48}](#), relative to the [meta^{p145}](#) element. If this fails, abort these steps.
24. Perform one or more of the following steps:
 - After the refresh has come due (as defined below), if the user has not canceled the redirect and if the [meta^{p145}](#) element's [node document's active sandboxing flag set^{p782}](#) does not have the [sandboxed automatic features browsing context flag^{p780}](#) set, [navigate^{b791}](#) the [Document^{p102}](#)'s [browsing context^{p762}](#) to *url*, with [replacement enabled^{p802}](#), and with the [Document^{p102}](#)'s [browsing context^{p762}](#) as the [source browsing context^{p791}](#).

For the purposes of the previous paragraph, a refresh is said to have come due as soon as the *later* of the following two conditions occurs:

- At least *time* seconds have elapsed since the document has [completely loaded^{p1033}](#), adjusted to take into account user or user agent preferences.
- At least *time* seconds have elapsed since the [meta^{p145}](#) element was [inserted into the Document^{p42}](#), adjusted to take into account user or user agent preferences.
- Provide the user with an interface that, when selected, [navigates^{b791}](#) a [browsing context^{p762}](#) to *url*, with the [Document^{p102}](#)'s [browsing context^{p762}](#) as the [source browsing context^{b791}](#).
- Do nothing.

In addition, the user agent may, as with anything, inform the user of any and all aspects of its operation, including the state of any timers, the destinations of any timed redirects, and so forth.

For [meta^{p145}](#) elements with an [http-equiv^{p149}](#) attribute in the [Refresh state^{p150}](#), the [content^{p146}](#) attribute must have a value consisting either of:

- just a [valid non-negative integer^{p61}](#), or
- a [valid non-negative integer^{p61}](#), followed by a U+003B SEMICOLON character (;), followed by one or more [space characters^{p58}](#), followed by a substring that is an [ASCII case-insensitive^{p58}](#) match for the string "URL", followed by a U+003D EQUALS SIGN character (=), followed by a [valid URL^{p81}](#) that does not start with a literal U+0027 APOSTROPHE ('') or U+0022 QUOTATION MARK ("") character.

In the former case, the integer represents a number of seconds before the page is to be reloaded; in the latter case the integer represents a number of seconds before the page is to be replaced by the page at the given [URL^{p48}](#).

Example

A news organization's front page could include the following markup in the page's `head`^{p138} element, to ensure that the page automatically reloads from the server every five minutes:

```
<meta http-equiv="Refresh" content="300">
```

Example A sequence of pages could be used as an automated slide show by making each page refresh to the next page in the sequence, using markup such as the following:

```
<meta http-equiv="Refresh" content="20; URL=page4.html">
```

Cookie setter (`http-equiv="set-cookie"`)

This pragma sets an HTTP cookie. [\[COOKIES\]](#)^{p1148}

It is non-conforming. Real HTTP headers should be used instead.

1. If the `meta`^{p145} element has no `content`^{p146} attribute, or if that attribute's value is the empty string, then abort these steps.
2. [Obtain the storage mutex](#)^{p838}.
3. Act as if [receiving a set-cookie-string](#)^{p49} for [the document's address](#) via a "non-HTTP" API, consisting of the value of the element's `content`^{p146} attribute encoded as UTF-8. [\[COOKIES\]](#)^{p1148} [\[ENCODING\]](#)^{p1150}

X-UA-Compatible state (`http-equiv="x-ua-compatible"`)

In practice, this pragma encourages Internet Explorer to more closely follow the specifications.

For `meta`^{p145} elements with an `http-equiv`^{p149} attribute in the [X-UA-Compatible state](#)^{p152}, the `content`^{p146} attribute must have the value "IE=edge".

User agents are required to ignore this pragma.

Spec bugs: [27164](#)

There must not be more than one `meta`^{p145} element with any particular state in the document at a time.

4.2.5.4 Other pragma directives

Extensions to the predefined set of pragma directives may, under certain conditions, be registered in the [WHATWG Wiki PragmaExtensions page](#). [\[WHATWGWIKI\]](#)^{p1154}

Such extensions must use a name that is identical to an HTTP header registered in the Permanent Message Header Field Registry, and must have behaviour identical to that described for the HTTP header. [\[IANAPERMHEADERS\]](#)^{p1150}

Pragma directives corresponding to headers describing metadata, or not requiring specific user agent processing, must not be registered; instead, use [metadata names](#)^{p148}. Pragma directives corresponding to headers that affect the HTTP processing model (e.g. caching) must not be registered, as they would result in HTTP-level behaviour being different for user agents that implement HTML than for user agents that do not.

Anyone is free to edit the WHATWG Wiki PragmaExtensions page at any time to add a pragma directive satisfying these conditions. Such registrations must specify the following information:

Keyword

The actual name being defined. The name must match a previously-registered HTTP name with the same requirements.

Brief description

A short non-normative description of the purpose of the pragma directive.

Specification

A link to the specification defining the corresponding HTTP header.

Conformance checkers must use the information given on the WHATWG Wiki PragmaExtensions page to establish if a value is allowed or not: values defined in this specification or listed on the aforementioned page must be accepted, whereas values not listed in either this specification or on the aforementioned page must be rejected as invalid. Conformance checkers may cache this information (e.g. for performance reasons or to avoid the use of unreliable network connectivity).

4.2.5.5 Specifying the document's character encoding

Spec bugs: 20742, 20743.
18338

A **character encoding declaration** is a mechanism by which the [character encoding](#)^{p44} used to store or transmit a document is specified.

The following restrictions apply to [character encoding declarations](#)^{p153}:

- The character encoding name given must be an [ASCII case-insensitive](#)^{p58} match for one of the [labels](#)^{p44} of the [character encoding](#)^{p44} used to serialise the file. [\[ENCODING\]](#)^{p1150}
- The character encoding declaration must be serialised without the use of [character references](#)^{p951} or character escapes of any kind.
- The element containing the character encoding declaration must be serialised completely within the first 1024 bytes of the document.

In addition, due to a number of restrictions on [meta](#)^{p145} elements, there can only be one [meta](#)^{p145}-based character encoding declaration per document.

If an [HTML document](#)^{p51} does not start with a BOM, and its [encoding](#)^{p44} is not explicitly given by [Content-Type metadata](#)^{p86}, and the document is not [an iframe srcdoc document](#)^{p300}, then the character encoding used must be an [ASCII-compatible character encoding](#)^{p44}, and the encoding must be specified using a [meta](#)^{p145} element with a [charset](#)^{p146} attribute or a [meta](#)^{p145} element with an [http-equiv](#)^{p149} attribute in the [Encoding declaration state](#)^{p150}.

Note A character encoding declaration is required (either in the [Content-Type metadata](#)^{p86} or explicitly in the file) even if the encoding is US-ASCII, because a character encoding is needed to process non-ASCII characters entered by the user in forms, in URLs generated by scripts, and so forth.

If the document is [an iframe srcdoc document](#)^{p300}, the document must not have a [character encoding declaration](#)^{p153}. (In this case, the source is already decoded, since it is part of the document that contained the [iframe](#)^{p299}.)

If an [HTML document](#)^{p51} contains a [meta](#)^{p145} element with a [charset](#)^{p146} attribute or a [meta](#)^{p145} element with an [http-equiv](#)^{p149} attribute in the [Encoding declaration state](#)^{p150}, then the character encoding used must be an [ASCII-compatible character encoding](#)^{p44}.

Authors should use UTF-8. Conformance checkers may advise authors against using legacy encodings. [\[ENCODING\]](#)^{p1150}

Authoring tools should default to using UTF-8 for newly-created documents. [\[ENCODING\]](#)^{p1150}

Encodings in which a series of bytes in the range 0x20 to 0x7E can encode characters other than the corresponding characters in the range U+0020 to U+007E represent a potential security vulnerability: a user agent that does not support the encoding (or does not support the label used to declare the encoding, or does not use the same mechanism to detect the encoding of unlabeled content as another user agent) might end up interpreting technically benign plain text content as HTML tags and JavaScript. Authors should therefore not use these encodings. For example, this applies to encodings in which the bytes corresponding to "<script>" in ASCII can encode a different string. Authors should not use such encodings, which are known to include JIS_C6226-1983, JIS_X0212-1990, HZ-GB-2312, JOHAB (Windows code page 1361), encodings based on ISO-2022, and encodings based on EBCDIC. Furthermore, authors must not use the CESU-8, UTF-7, BOCU-1 and SCSU encodings, which also fall into this category; these encodings were never intended for use for Web content. [\[RFC1345\]](#)^{p152} [\[RFC1842\]](#)^{p1152} [\[RFC1468\]](#)^{p1152} [\[RFC2237\]](#)^{p1152} [\[RFC1554\]](#)^{p1152} [\[CP50220\]](#)^{p1148} [\[RFC1922\]](#)^{p1152} [\[RFC1557\]](#)^{p1152} [\[CESU8\]](#)^{p1148} [\[UTF7\]](#)^{p1154} [\[BOCU1\]](#)^{p1148} [\[SCSU\]](#)^{p1153}

Authors should not use UTF-32, as the encoding detection algorithms described in this specification intentionally do not distinguish it from UTF-16. [\[UNICODE\]](#)^{p1153}

Note Using non-UTF-8 encodings can have unexpected results on form submission and URL encodings, which use the [document's character encoding](#)^{p51} by default.

In XHTML, the XML declaration should be used for inline character encoding information, if necessary.

Example

In HTML, to declare that the character encoding is UTF-8, the author could include the following markup near the top of the document (in the [head](#)^{p138} element):

```
<meta charset="utf-8">
```

In XML, the XML declaration would be used instead, at the very top of the markup:

```
<?xml version="1.0" encoding="utf-8"?>
```

4.2.6 The `style` element

Categories^{p113}:

[Metadata content](#)^{p115}.

If the [scoped](#)^{p154} attribute is present: [flow content](#)^{p115}.

Contexts in which this element can be used^{p113}:

If the [scoped](#)^{p154} attribute is absent: where [metadata content](#)^{p115} is expected.

If the [scoped](#)^{p154} attribute is absent: in a [noscript](#)^{p602} element that is a child of a [head](#)^{p138} element.

If the [scoped](#)^{p154} attribute is present: where [flow content](#)^{p115} is expected, but before any other [flow content](#)^{p115} other than [inter-element whitespace](#)^{p113} and [style](#)^{p154} elements, and not as the child of an element whose content model is [transparent](#)^{p117}.

Content model^{p113}:

Depends on the value of the [type](#)^{p154} attribute, but must match requirements described in prose below.

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes](#)^{p120}

[media](#)^{p154} — Applicable media

[type](#)^{p154} — Type of embedded resource

[scoped](#)^{p154} — Whether the styles apply to the entire document or just the parent subtree

Also, the [title](#)^{p155} attribute [has special semantics](#)^{p155} on this element: Alternative style sheet set name.

DOM interface^{p113}:

```
IDL
interface HTMLStyleElement : HTMLElement {
  attribute DOMString media;
  attribute DOMString type;
  attribute boolean scoped;
};

HTMLStyleElement implements LinkStyle;
```

The [style](#)^{p154} element allows authors to embed style information in their documents. The [style](#)^{p154} element is one of several inputs to the styling processing model. The element does not [represent](#)^{p111} content for the user.

The [type](#) attribute gives the styling language. If the attribute is present, its value must be a [valid MIME type](#)^{p42} that designates a styling language. The [charset](#) parameter must not be specified. The default value for the [type](#)^{p154} attribute, which is used if the attribute is absent, is "text/css". [\[RFC2318\]](#)^{p152}

When examining types to determine if they support the language, user agents must not ignore unknown MIME parameters — types with unknown parameters must be assumed to be unsupported. The [charset](#) parameter must be treated as an unknown parameter for the purpose of comparing [MIME types](#)^{p42} here.

The [media](#) attribute says which media the styles apply to. The value must be a [valid media query list](#)^{p81}. The user agent must apply the styles when the [media](#)^{p154} attribute's value [matches the environment](#)^{p81} and the other relevant conditions apply, and must not apply them otherwise.

Note *The styles might be further limited in scope, e.g. in CSS with the use of @media blocks. This specification does not override such further restrictions or requirements.*

The default, if the [media](#)^{p154} attribute is omitted, is "all", meaning that by default styles apply to all media.

The [scoped](#) attribute is a [boolean attribute](#)^{p59}. If present, it indicates that the styles are intended just for the subtree rooted at the [style](#)^{p154} element's parent element, as opposed to the whole [Document](#)^{p102}.

If the [scoped](#)^{p154} attribute is present and the element has a parent element, then the [style](#)^{p154} element must precede any [flow](#)^{p115} parent element other than [inter-element whitespace](#)^{p113} and other [style](#)^{p154} elements, and the parent element's content model must be [transparent](#)^{p117} component.

Source: [caniuse.com](#)

Note This implies that scoped `stylep154` elements cannot be children of, e.g., `ap208` or `insp260` elements, even when those are used as `flow contentp115` containers.

Note A `stylep154` element without a `scopedp154` attribute is restricted to appearing in the `headp138` of the document.

A style sheet declared by a `stylep154` element that has a `scopedp154` attribute and has a parent node that is an element is *scoped*, with the *scoping root* being the `stylep154` element's parent element. [CSSSCOPED]^{p1149}

The `title` attribute on `stylep154` elements defines *alternative style sheet sets*^{p53}. If the `stylep154` element has no `titlep155` attribute, then it has no title; the `titlep122` attribute of ancestors does not apply to the `stylep154` element. [CSSOM]^{p1149}

Note The `titlep155` attribute on `stylep154` elements, like the `titlep144` attribute on `linkp141` elements, differs from the global `titlep122` attribute in that a `stylep154` block without a title does not inherit the title of the parent element: it merely has no title.

The `textContentp51` of a `stylep154` element must match the `style` production in the following ABNF, the character set for which is Unicode. [ABNF]^{p1148}

```
style      = no-c-start *( c-start no-c-end c-end no-c-start )
no-c-start = < any string that doesn't contain a substring that matches c-start >
c-start    = "<!--"
no-c-end   = < any string that doesn't contain a substring that matches c-end >
c-end      = "-->"
```

Whenever one of the following conditions occur for an element whose `Documentp102` is in a `browsing contextp762`:

- the element is popped off the `stack of open elementsp962` of an `HTML parserp952` or `XML parserp1054`,
- the element is not on the `stack of open elementsp962` of an `HTML parserp952` or `XML parserp1054`, and it is *inserted into a document*^{p42} or *removed from a document*^{p42},
- the element is not on the `stack of open elementsp962` of an `HTML parserp952` or `XML parserp1054`, and one of its child nodes is modified by a script,

...the user agent must run the `update a style block` algorithm that applies for the style sheet language specified by the element's `typep154` attribute, passing it the element's **style data**.

For styling languages that consist of pure text (as opposed to XML), a `stylep154` element's **style data**^{p155} is the concatenation of the contents of all the `Textp51` nodes that are children of the `stylep154` element (not any other nodes such as comments or elements), in `tree orderp42`. For XML-based styling languages, the `style data`^{p155} consists of all the child nodes of the `stylep154` element.

The `update a style blockp155` algorithm for CSS (`text/cssp1146`) is as follows:

1. Let `element` be the `stylep154` element.
2. If `element` has an `associated CSS style sheetp53`, remove the `CSS style sheetp53` in question.
3. If `element` is not *in a Document*^{p42}, then abort these steps.
4. `Create a CSS style sheetp53` with the following properties:

`typep53`
`text/css`

`owner nodep53`
`element`

`mediap53`
The `mediap154` attribute of `element`.

Note This is a reference to the (possibly absent at this time) attribute, rather than a copy of the attribute's current value. The CSSOM specification defines what happens when the attribute is dynamically set, changed, or removed.

[title](#)^{p53}

The [title](#)^{p155} attribute of [element](#).

Note Again, this is a reference to the attribute.

[alternate flag](#)^{p53}

Unset.

[origin-clean flag](#)^{p53}

Set.

[location](#)^{p53}

[parent CSS style sheet](#)^{p53}

[owner CSS rule](#)^{p53}

null

[disabled flag](#)^{p53}

Left at its default value.

[CSS rules](#)^{p53}

Left uninitialised.

This specification does not define any other styling language's [update a style block](#)^{p155} algorithm.

Once the attempts to obtain the style sheet's [critical subresources](#)^{p42}, if any, are complete, or, if the style sheet has no [critical subresources](#)^{p42}, once the style sheet has been parsed and processed, the user agent must, if the loads were successful or there were none, [queue a task](#)^{p835} to [fire a simple event](#)^{p846} named [load](#)^{p1144} at the [style](#)^{p154} element, or, if one of the style sheet's [critical subresources](#)^{p42} failed to completely load for any reason (e.g. DNS error, HTTP 404 response, a connection being prematurely closed, unsupported Content-Type), [queue a task](#)^{p835} to [fire a simple event](#)^{p846} named [error](#)^{p1144} at the [style](#)^{p154} element. Non-network errors in processing the style sheet or its subresources (e.g. CSS parse errors, PNG decoding errors) are not failures for the purposes of this paragraph.

The [task source](#)^{p835} for these [tasks](#)^{p834} is the [DOM manipulation task source](#)^{p838}.

The element must [delay the load event](#)^{p1033} of the element's [node document](#) until all the attempts to obtain the style sheet's [critical subresources](#)^{p42}, if any, are complete.

Note This specification does not specify a style system, but CSS is expected to be supported by most Web browsers. [\[CSS\]](#)^{p1149}

The [media](#), [type](#) and [scoped](#) IDL attributes must [reflect](#)^{p88} the respective content attributes of the same name.

The [LinkStyle](#)^{p53} interface is also implemented by this element. [\[CSSOM\]](#)^{p1149}

Example

The following document has its stress emphasis styled as bright red text rather than italics text, while leaving titles of works and Latin words in their default italics. It shows how using appropriate elements enables easier restyling of documents.

```
<!DOCTYPE html>
<html lang="en-US">
  <head>
    <title>My favorite book</title>
    <style>
      body { color: black; background: white; }
      em { font-style: normal; color: red; }
    </style>
  </head>
  <body>
    <p>My <em>favorite</em> book of all time has <em>got</em> to be
      <cite>A Cat's Life</cite>. It is a book by P. Rahmel that talks
      about the <i lang="la">Felis Catus</i> in modern human society.</p>
  </body>
</html>
```

4.2.7 Interactions of styling and scripting

Style sheets, whether added by a [link](#)^{p141} element, a [style](#)^{p154} element, an [<?xml-stylesheet?>](#) PI, an HTTP [Link:](#)^{p49} header, or some other mechanism, have a **style sheet ready** flag, which is initially unset.

When a style sheet is ready to be applied, its [style sheet ready](#)^{p157} flag must be set. If the style sheet referenced no other resources (e.g. it was an internal style sheet given by a [style](#)^{p154} element with no `@import` rules), then the style rules must be [immediately](#)^{p41} made available to script; otherwise, the style rules must only be made available to script once the [event loop](#)^{p834} reaches its *update the rendering* step.

A style sheet in the context of the [Document](#)^{p102} of an [HTML parser](#)^{p952} or [XML parser](#)^{p1054} is said to be a **style sheet that is blocking scripts** if the element was created by that [Document](#)^{p102}'s parser, and the element is either a [style](#)^{p154} element or a [link](#)^{p141} element that was an [external resource link that contributes to the styling processing model](#)^{p256} when the element was created by the parser, and the element's style sheet was enabled when the element was created by the parser, and the element's [style sheet ready](#)^{p157} flag is not yet set, and, the last time the [event loop](#)^{p834} reached [step 1](#)^{p836}, the element was [in that Document](#)^{p42}, and the user agent hasn't given up on that particular style sheet yet. A user agent may give up on a style sheet at any time.

Note *Giving up on a style sheet before the style sheet loads, if the style sheet eventually does still load, means that the script might end up operating with incorrect information. For example, if a style sheet sets the colour of an element to green, but a script that inspects the resulting style is executed before the sheet is loaded, the script will find that the element is black (or whatever the default colour is), and might thus make poor choices (e.g. deciding to use black as the colour elsewhere on the page, instead of green). Implementors have to balance the likelihood of a script using incorrect information with the performance impact of doing nothing while waiting for a slow network request to finish.*

A [Document](#)^{p102} has a **style sheet that is blocking scripts** if there is either [a style sheet that is blocking scripts](#)^{p157} in the context of that [Document](#)^{p102}, or if that [Document](#)^{p102} is in a [browsing context](#)^{p762} that has a [parent browsing context](#)^{p763}, and the [active document](#)^{p762} of that [parent browsing context](#)^{p763} itself [has a style sheet that is blocking scripts](#)^{p157}.

A [Document](#)^{p102} has **no style sheet that is blocking scripts** if it does not [have a style sheet that is blocking scripts](#)^{p157} as defined in the previous paragraph.

4.3 Sections

4.3.1 The `body` element

Categories^{p113}:

[Sectioning root](#)^{p176}.

Contexts in which this element can be used^{p113}:

As the second element in an [html](#)^{p137} element.

Content model^{p113}:

[Flow content](#)^{p115}.

Tag omission in text/html^{p113}:

A [body](#)^{p157} element's [start tag](#)^{p944} can be omitted if the element is empty, or if the first thing inside the [body](#)^{p157} element is not a [space character](#)^{p58} or a [comment](#)^{p952}, except if the first thing inside the [body](#)^{p157} element is a [meta](#)^{p145}, [link](#)^{p141}, [script](#)^{p591}, [style](#)^{p154}, or [template](#)^{p604} element.

A [body](#)^{p157} element's [end tag](#)^{p944} can be omitted if the [body](#)^{p157} element is not immediately followed by a [comment](#)^{p952}.

Content attributes^{p113}:

[Global attributes](#)^{p120}

[onafterprint](#)^{p844}

[onbeforeprint](#)^{p844}

[onbeforeunload](#)^{p844}

[onhashchange](#)^{p844}

[onlanguagechange](#)^{p844}

[onmessage](#)^{p844}

[onoffline](#)^{p844}

[ononline](#)^{p844}

Support:	
Chrome	6+
IE	9+
Chrome for Android	40+
Firefox	4+
iOS Safari	4.0-4.1+
Android Browser	2.2+

Source: [caniuse.com](#)

onpagehide^{p844}
onpageshow^{p844}
onpopstate^{p844}
onstorage^{p844}
onunload^{p844}

DOM interface^{p113}:

IDL	<pre>interface HTMLBodyElement : HTMLElement { // also has obsolete members }; HTMLBodyElement implements WindowEventHandlers;</pre>
-----	--

The body^{p157} element represents^{p111} the main content of the document.

In conforming documents, there is only one body^{p157} element. The document.body^{p106} IDL attribute provides scripts with easy access to a document's body^{p157} element.

Note Some DOM operations (for example, parts of the drag and drop^{p743} model) are defined in terms of "the body element^{p106}". This refers to a particular element in the DOM, as per the definition of the term, and not any arbitrary body^{p157} element.

The body^{p157} element exposes as event handler content attributes^{p839} a number of the event handlers^{p839} of the Window^{p768} object. It also mirrors their event handler IDL attributes^{p839}.

The onblur^{p844}, onerror^{p844}, onfocus^{p844}, onload^{p844}, onresize^{p844}, and onscroll^{p844} event handlers^{p839} of the Window^{p768} object, exposed on the body^{p157} element, replace the generic event handlers^{p839} with the same names normally supported by HTML elements^{p42}.

Example Thus, for example, a bubbling error^{p1144} event dispatched on a child of the body element^{p106} of a Document^{p102} would first trigger the onerror^{p844} event handler content attributes^{p839} of that element, then that of the root html^{p137} element, and only *then* would it trigger the onerror^{p844} event handler content attribute^{p839} on the body^{p157} element. This is because the event would bubble from the target, to the body^{p157}, to the html^{p137}, to the Document^{p102}, to the Window^{p768}, and the event handler^{p839} on the body^{p157} is watching the Window^{p768} not the body^{p157}. A regular event listener attached to the body^{p157} using addEventListener(), however, would be run when the event bubbled through the body^{p157} and not when it reaches the Window^{p768} object.

Example

This page updates an indicator to show whether or not the user is online:

```
<!DOCTYPE HTML>  
<html>  
  <head>  
    <title>Online or offline?</title>  
    <script>  
      function update(online) {  
        document.getElementById('status').textContent =  
          online ? 'Online' : 'Offline';  
      }  
    </script>  
  </head>  
  <body ononline="update(true)"  
        onoffline="update(false)"  
        onload="update(navigator.onLine)">  
    <p>You are: <span id="status">(Unknown)</span></p>  
  </body>  
</html>
```

4.3.2 The `article` element

Categories^{p113}:

[Flow content](#)^{p115}.
[Sectioning content](#)^{p116}.
[Palpable content](#)^{p117}.

Contexts in which this element can be used^{p113}:

Where [flow content](#)^{p115} is expected.

Content model^{p113}:

[Flow content](#)^{p115}.

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes](#)^{p120}

DOM interface^{p113}:

Uses [HTMLElement](#)^{p112}.

The [article](#)^{p159} element [represents](#)^{p111} a complete, or self-contained, composition in a document, page, application, or site and that is, in principle, independently distributable or reusable, e.g. in syndication. This could be a forum post, a magazine or newspaper article, a blog entry, a user-submitted comment, an interactive widget or gadget, or any other independent item of content.

When [article](#)^{p159} elements are nested, the inner [article](#)^{p159} elements represent articles that are in principle related to the contents of the outer article. For instance, a blog entry on a site that accepts user-submitted comments could represent the comments as [article](#)^{p159} elements nested within the [article](#)^{p159} element for the blog entry.

Author information associated with an [article](#)^{p159} element (q.v. the [address](#)^{p175} element) does not apply to nested [article](#)^{p159} elements.

Note When used specifically with content to be redistributed in syndication, the [article](#)^{p159} element is similar in purpose to the [entry](#) element in Atom. [\[ATOM\]](#)^{p1148}

Note The schema.org microdata vocabulary can be used to provide the publication date for an [article](#)^{p159} element, using one of the CreativeWork subtypes.

When the main content of the page (i.e. excluding footers, headers, navigation blocks, and sidebars) is all one single self-contained composition, that content may be marked with an [article](#)^{p159}, but it is technically redundant in that case (since it's self-evident that the page is a single composition, as it is a single document).

Example

This example shows a blog post using the [article](#)^{p159} element, with some schema.org annotations:

```
<article itemscope itemtype="http://schema.org/BlogPosting">
  <header>
    <h1 itemprop="headline">The Very First Rule of Life</h1>
    <p><time itemprop="datePublished" datetime="2009-10-09">3 days ago</time></p>
    <link itemprop="url" href="?comments=0">
  </header>
  <p>If there's a microphone anywhere near you, assume it's hot and
  sending whatever you're saying to the world. Seriously.</p>
  <p>...</p>
  <footer>
    <a itemprop="discussionUrl" href="?comments=1">Show comments...</a>
  </footer>
</article>
```

Here is that same blog post, but showing some of the comments:

```
<article itemscope itemtype="http://schema.org/BlogPosting">
  <header>
```

```

<h1 itemprop="headline">The Very First Rule of Life</h1>
<p><time itemprop="datePublished" datetime="2009-10-09">3 days ago</time></p>
<link itemprop="url" href="?comments=0">
</header>
<p>If there's a microphone anywhere near you, assume it's hot and
sending whatever you're saying to the world. Seriously.</p>
<p>...</p>
<section>
  <h1>Comments</h1>
  <article itemprop="comment" itemscope itemtype="http://schema.org/UserComments" id="c1">
    <link itemprop="url" href="#c1">
    <footer>
      <p>Posted by: <span itemprop="creator" itemscope itemtype="http://schema.org/Person">
        <span itemprop="name">George Washington</span>
      </span></p>
      <p><time itemprop="commentTime" datetime="2009-10-10">15 minutes ago</time></p>
    </footer>
    <p>Yeah! Especially when talking about your lobbyist friends!</p>
  </article>
  <article itemprop="comment" itemscope itemtype="http://schema.org/UserComments" id="c2">
    <link itemprop="url" href="#c2">
    <footer>
      <p>Posted by: <span itemprop="creator" itemscope itemtype="http://schema.org/Person">
        <span itemprop="name">George Hammond</span>
      </span></p>
      <p><time itemprop="commentTime" datetime="2009-10-10">5 minutes ago</time></p>
    </footer>
    <p>Hey, you have the same first name as me.</p>
  </article>
  </section>
</article>

```

Notice the use of [footer^{p173}](#) to give the information for each comment (such as who wrote it and when): the [footer^{p173}](#) element can appear at the start of its section when appropriate, such as in this case. (Using [header^{p171}](#) in this case wouldn't be wrong either; it's mostly a matter of authoring preference.)

Example

In this example, [article^{p159}](#) elements are used to host widgets on a portal page.

```

<!DOCTYPE HTML>
<title>eHome Portal</title>
<link rel="stylesheet" href="/styles/main.css">
<article>
  <style scoped> @import url(/widgets/stocks/look.css); </style>
  <script src="/widgets/stocks/core.js"></script>
  <h1>Stocks</h1>
  <table>
    <thead> <tr> <th> Stock <th> Value <th> Delta
    <tbody> <template> <tr> <td> <td> <td> </template>
  </table>
  <p> <input type="button" value="Refresh" onclick="stocks.refresh()">
</article>
<article>
  <style scoped> @import url(/widgets/news/look.css); </style>
  <script src="/widgets/news/core.js"></script>
  <h1>News</h1>
  <ul>
    <template>
      <li>
        <p><img> <strong></strong>
        <p>
```

```

        </template>
    </ul>
    <p> <input type="button" value="Refresh" onclick="news.refresh()">
</article>

```

4.3.3 The **section** element

Categories^{p113}:

[Flow content](#)^{p115}.
[Sectioning content](#)^{p116}.
[Palpable content](#)^{p117}.

Contexts in which this element can be used^{p113}:

Where [flow content](#)^{p115} is expected.

Content model^{p113}:

[Flow content](#)^{p115}.

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes](#)^{p120}

DOM interface^{p113}:

Uses [HTMLElement](#)^{p112}.

The [section](#)^{p161} element [represents](#)^{p111} a generic section of a document or application. A section, in this context, is a thematic grouping of content, typically with a heading.

Example Examples of sections would be chapters, the various tabbed pages in a tabbed dialog box, or the numbered sections of a thesis. A Web site's home page could be split into sections for an introduction, news items, and contact information.

Note Authors are encouraged to use the [article](#)^{p159} element instead of the [section](#)^{p161} element when it would make sense to syndicate the contents of the element.

Note The [section](#)^{p161} element is not a generic container element. When an element is needed only for styling purposes or as a convenience for scripting, authors are encouraged to use the [div](#)^{p207} element instead. A general rule is that the [section](#)^{p161} element is appropriate only if the element's contents would be listed explicitly in the document's [outline](#)^{p178}.

Example In the following example, we see an article (part of a larger Web page) about apples, containing two short sections.

```

<article>
    <hgroup>
        <h1>Apples</h1>
        <h2>Tasty, delicious fruit!</h2>
    </hgroup>
    <p>The apple is the pomaceous fruit of the apple tree.</p>
    <section>
        <h1>Red Delicious</h1>
        <p>These bright red apples are the most common found in many
            supermarkets.</p>
    </section>
    <section>
        <h1>Granny Smith</h1>
        <p>These juicy, green apples make a great filling for
            apple pies.</p>
    </section>
</article>

```

Notice how the use of `section`^{p161} means that the author can use `h1`^{p168} elements throughout, without having to worry about whether a particular section is at the top level, the second level, the third level, and so on.

Example

Here is a graduation programme with two sections, one for the list of people graduating, and one for the description of the ceremony. (The markup in this example features an uncommon style sometimes used to minimise the amount of `inter-element whitespace`^{p113}.)

```
<!DOCTYPE Html>
<Html
  ><Head
    ><Title
      >Graduation Ceremony Summer 2022</Title
    ></Head
  ><Body
    ><H1
      >Graduation</H1
    ><Section
      ><H1
        >Ceremony</H1
      ><P
        >Opening Procession</P
      ><P
        >Speech by Validactorian</P
      ><P
        >Speech by Class President</P
      ><P
        >Presentation of Diplomas</P
      ><P
        >Closing Speech by Headmaster</P
    ></Section
    ><Section
      ><H1
        >Graduates</H1
      ><Ul
        ><Li
          >Molly Carpenter</Li
        ><Li
          >Anastasia Luccio</Li
        ><Li
          >Ebenezar McCoy</Li
        ><Li
          >Karrin Murphy</Li
        ><Li
          >Thomas Raith</Li
        ><Li
          >Susan Rodriguez</Li
      ></Ul
    ></Section
  ></Body
></Html>
```

Example

In this example, a book author has marked up some sections as chapters and some as appendices, and uses CSS to style the headers in these two classes of section differently. The whole book is wrapped in an `article`^{p159} element as part of an even larger document containing other books.

```
<article class="book">
  <style>
    section { border: double medium; margin: 2em; }
    section.chapter h1 { font: 2em Roboto, Helvetica Neue, sans-serif; }
    section.appendix h1 { font: small-caps 2em Roboto, Helvetica Neue, sans-serif; }
  </style>
```

```

<header>
  <hgroup>
    <h1>My Book</h1>
    <h2>A sample with not much content</h2>
  </hgroup>
  <p><small>Published by Dummy Publicorp Ltd.</small></p>
</header>
<section class="chapter">
  <h1>My First Chapter</h1>
  <p>This is the first of my chapters. It doesn't say much.</p>
  <p>But it has two paragraphs!</p>
</section>
<section class="chapter">
  <h1>It Continutes: The Second Chapter</h1>
  <p>Bla dee bla, dee bla dee bla. Boom.</p>
</section>
<section class="chapter">
  <h1>Chapter Three: A Further Example</h1>
  <p>It's not like a battle between brightness and earthtones would go unnoticed.</p>
  <p>But it might ruin my story.</p>
</section>
<section class="appendix">
  <h1>Appendix A: Overview of Examples</h1>
  <p>These are demonstrations.</p>
</section>
<section class="appendix">
  <h1>Appendix B: Some Closing Remarks</h1>
  <p>Hopefully this long example shows that you <em>can</em> style sections, so long as they are used to indicate actual sections.</p>
</section>
</article>

```

4.3.4 The `nav` element

Spec bugs: [18245](#)

Categories^{p113}:

[Flow content](#)^{p115}.

[Sectioning content](#)^{p116}.

[Palpable content](#)^{p117}.

Contexts in which this element can be used^{p113}:

Where [flow content](#)^{p115} is expected.

Content model^{p113}:

[Flow content](#)^{p115}, but with no [main](#)^{p205} element descendants.

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes](#)^{p120}

DOM interface^{p113}:

Uses [HTMLElement](#)^{p112}.

The [nav](#)^{p163} element [represents](#)^{p111} a section of a page that links to other pages or to parts within the page: a section with navigation links.

Note Not all groups of links on a page need to be in a [nav](#)^{p163} element — the element is primarily intended for sections that consist of major navigation blocks. In particular, it is common for footers to have a short list of links to various pages of a site, such as the terms of service,

the home page, and a copyright page. The `footerp173` element alone is sufficient for such cases; while a `navp163` element can be used in such cases, it is usually unnecessary.

Note User agents (such as screen readers) that are targeted at users who can benefit from navigation information being omitted in the initial rendering, or who can benefit from navigation information being immediately available, can use this element as a way to determine what content on the page to initially skip or provide on request (or both).

Example

In the following example, there are two `navp163` elements, one for primary navigation around the site, and one for secondary navigation around the page itself.

```
<body>
  <h1>The Wiki Center Of Exampland</h1>
  <nav>
    <ul>
      <li><a href="/">Home</a></li>
      <li><a href="/events">Current Events</a></li>
        ...more...
    </ul>
  </nav>
  <article>
    <header>
      <h1>Demos in Exampland</h1>
      <p>Written by A. N. Other.</p>
    </header>
    <nav>
      <ul>
        <li><a href="#public">Public demonstrations</a></li>
        <li><a href="#destroy">Demolitions</a></li>
          ...more...
      </ul>
    </nav>
    <div>
      <section id="public">
        <h1>Public demonstrations</h1>
        <p>...more...</p>
      </section>
      <section id="destroy">
        <h1>Demolitions</h1>
        <p>...more...</p>
      </section>
      ...more...
    </div>
    <footer>
      <p><a href="?edit">Edit</a> | <a href="?delete">Delete</a> | <a href="?Rename">Rename</a></p>
    </footer>
  </article>
  <footer>
    <p><small>© copyright 1998 Exampland Emperor</small></p>
  </footer>
</body>
```

Example

In the following example, the page has several places where links are present, but only one of those places is considered a navigation section.

```
<body itemscope itemtype="http://schema.org/Blog">
  <header>
    <h1>Wake up sheeple!</h1>
    <p><a href="news.html">News</a> -
      <a href="blog.html">Blog</a> -
      <a href="forums.html">Forums</a></p>
```

```

<p>Last Modified: <span itemprop="dateModified">2009-04-01</span></p>
<nav>
  <h1>Navigation</h1>
  <ul>
    <li><a href="articles.html">Index of all articles</a></li>
    <li><a href="today.html">Things sheeple need to wake up for today</a></li>
    <li><a href="successes.html">Sheeple we have managed to wake</a></li>
  </ul>
</nav>
</header>
<main>
  <article itemprop="blogPosts" itemscope itemtype="http://schema.org/BlogPosting">
    <header>
      <h1 itemprop="headline">My Day at the Beach</h1>
    </header>
    <main itemprop="articleBody">
      <p>Today I went to the beach and had a lot of fun.</p>
      ...more content...
    </main>
    <footer>
      <p>Posted <time itemprop="datePublished" datetime="2009-10-10">Thursday</time>. </p>
    </footer>
  </article>
  ...more blog posts...
</main>
<footer>
  <p>Copyright ©
    <span itemprop="copyrightYear">2010</span>
    <span itemprop="copyrightHolder">The Example Company</span>
  </p>
  <p><a href="about.html">About</a> -
    <a href="policy.html">Privacy Policy</a> -
    <a href="contact.html">Contact Us</a></p>
</footer>
</body>

```

Notice the [main^{p205}](#) elements being used to wrap all the contents of the page other than the header and footer, and all the contents of the blog entry other than its header and footer.

You can also see microdata annotations in the above example that use the schema.org vocabulary to provide the publication date and other metadata about the blog post.

Example

A [nav^{p163}](#) element doesn't have to contain a list, it can contain other kinds of content as well. In this navigation block, links are provided in prose:

```

<nav>
  <h1>Navigation</h1>
  <p>You are on my home page. To the north lies <a href="/blog">my
  blog</a>, from whence the sounds of battle can be heard. To the east
  you can see a large mountain, upon which many <a
  href="/school">school papers</a> are littered. Far up thus mountain
  you can spy a little figure who appears to be me, desperately
  scribbling a <a href="/school/thesis">thesis</a>. </p>
  <p>To the west are several exits. One fun-looking exit is labeled <a
  href="http://games.example.com/">games</a>. Another more
  boring-looking exit is labeled <a
  href="http://isp.example.net/">ISP™</a>. </p>
  <p>To the south lies a dark and dank <a href="/about">contacts
  page</a>. Cobwebs cover its disused entrance, and at one point you

```

```
see a rat run quickly out of the page.</p>
</nav>
```

Example

In this example, `navp163` is used in an e-mail application, to let the user switch folders:

```
<p><input type=button value="Compose" onclick="compose()"></p>
<nav>
  <h1>Folders</h1>
  <ul>
    <li> <a href="/inbox" onclick="return openFolder(this.href)">Inbox</a> <span
        class=count></span>
    <li> <a href="/sent" onclick="return openFolder(this.href)">Sent</a>
    <li> <a href="/drafts" onclick="return openFolder(this.href)">Drafts</a>
    <li> <a href="/trash" onclick="return openFolder(this.href)">Trash</a>
    <li> <a href="/customers" onclick="return openFolder(this.href)">Customers</a>
  </ul>
</nav>
```

4.3.5 The `aside` element

Categories^{p113}:

[Flow content^{p115}](#).

[Sectioning content^{p116}](#).

[Palpable content^{p117}](#).

Contexts in which this element can be used^{p113}:

Where [flow content^{p115}](#) is expected.

Content model^{p113}:

[Flow content^{p115}](#), but with no [main^{p205}](#) element descendants.

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes^{p120}](#)

DOM interface^{p113}:

Uses [HTMLElement^{p112}](#).

The `asidep166` element [represents^{p111}](#) a section of a page that consists of content that is tangentially related to the content around the `asidep166` element, and which could be considered separate from that content. Such sections are often represented as sidebars in printed typography.

The element can be used for typographical effects like pull quotes or sidebars, for advertising, for groups of `navp163` elements, and for other content that is considered separate from the main content of the page.

Note *It's not appropriate to use the `asidep166` element just for parentheticals, since those are part of the main flow of the document.*

Example

The following example shows how an aside is used to mark up background material on Switzerland in a much longer news story on Europe.

```
<aside>
  <h1>Switzerland</h1>
  <p>Switzerland, a land-locked country in the middle of geographic
  Europe, has not joined the geopolitical European Union, though it is
  a signatory to a number of European treaties.</p>
</aside>
```

Example

The following example shows how an aside is used to mark up a pull quote in a longer article.

```
...  

<p>He later joined a large company, continuing on the same work.  
<q>I love my job. People ask me what I do for fun when I'm not at  
work. But I'm paid to do my hobby, so I never know what to  
answer. Some people wonder what they would do if they didn't have to  
work... but I know what I would do, because I was unemployed for a  
year, and I filled that time doing exactly what I do now.</q></p>  
  
<aside>  
  <q> People ask me what I do for fun when I'm not at work. But I'm  
  paid to do my hobby, so I never know what to answer. </q>  
</aside>  
  
<p>Of course his work – or should that be hobby? –  
isn't his only passion. He also enjoys other pleasures.</p>  
  
...

```

Example

The following extract shows how aside^{p166} can be used for blogrolls and other side content on a blog:

```
<body>  
  <header>  
    <h1>My wonderful blog</h1>  
    <p>My tagline</p>  
  </header>  
  <aside>  
    <!-- this aside contains two sections that are tangentially related  
    to the page, namely, links to other blogs, and links to blog posts  
    from this blog -->  
    <nav>  
      <h1>My blogroll</h1>  
      <ul>  
        <li><a href="http://blog.example.com/">Example Blog</a>  
      </ul>  
    </nav>  
    <nav>  
      <h1>Archives</h1>  
      <ol reversed>  
        <li><a href="/last-post">My last post</a>  
        <li><a href="/first-post">My first post</a>  
      </ol>  
    </nav>  
  </aside>  
  <aside>  
    <!-- this aside is tangentially related to the page also, it  
    contains twitter messages from the blog author -->  
    <h1>Twitter Feed</h1>  
    <blockquote cite="http://twitter.example.net/t31351234">  
      I'm on vacation, writing my blog.  
    </blockquote>  
    <blockquote cite="http://twitter.example.net/t31219752">  
      I'm going to go on vacation soon.  
    </blockquote>  
  </aside>  
  <article>  
    <!-- this is a blog post -->  
    <h1>My last post</h1>
```

```

<p>This is my last post.</p>
<footer>
  <p><a href="/last-post" rel=bookmark>Permalink</a>
</footer>
</article>
<article>
  <!-- this is also a blog post -->
  <h1>My first post</h1>
  <p>This is my first post.</p>
  <aside>
    <!-- this aside is about the blog post, since it's inside the
        <article> element; it would be wrong, for instance, to put the
        blogroll here, since the blogroll isn't really related to this post
        specifically, only to the page as a whole -->
    <h1>Posting</h1>
    <p>While I'm thinking about it, I wanted to say something about
      posting. Posting is fun!</p>
  </aside>
  <footer>
    <p><a href="/first-post" rel=bookmark>Permalink</a>
  </footer>
</article>
<footer>
  <nav>
    <a href="/archives">Archives</a> -
    <a href="/about">About me</a> -
    <a href="/copyright">Copyright</a>
  </nav>
</footer>
</body>

```

4.3.6 The **h1**, **h2**, **h3**, **h4**, **h5**, and **h6** elements

Categories^{p113}:

[Flow content](#)^{p115}.
[Heading content](#)^{p116}.
[Palpable content](#)^{p117}.

Contexts in which this element can be used^{p113}:

As a child of an [hgroup](#)^{p170} element.
 Where [flow content](#)^{p115} is expected.

Content model^{p113}:

[Phrasing content](#)^{p116}.

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes](#)^{p120}

DOM interface^{p113}:

IDL	<pre>interface HTMLHeadingElement : HTMLElement { // also has obsolete members };</pre>
-----	---

These elements [represent](#)^{p111} headings for their sections.

The semantics and meaning of these elements are defined in the section on [headings and sections^{p176}](#).

These elements have a **rank** given by the number in their name. The [h1^{p168}](#) element is said to have the highest rank, the [h6^{p168}](#) element has the lowest rank, and two elements with the same name have equal rank.

Example

As far as their respective document outlines (their heading and section structures) are concerned, these two snippets are semantically equivalent:

```
<body>
<h1>Let's call it a draw(ing surface)</h1>
<h2>Diving in</h2>
<h2>Simple shapes</h2>
<h2>Canvas coordinates</h2>
<h3>Canvas coordinates diagram</h3>
<h2>Paths</h2>
</body>

<body>
<h1>Let's call it a draw(ing surface)</h1>
<section>
<h1>Diving in</h1>
</section>
<section>
<h1>Simple shapes</h1>
</section>
<section>
<h1>Canvas coordinates</h1>
</section>
<section>
<h1>Canvas coordinates diagram</h1>
</section>
<section>
<h1>Paths</h1>
</section>
</body>
```

Authors might prefer the former style for its terseness, or the latter style for its convenience in the face of heavy editing; which is best is purely an issue of preferred authoring style.

The two styles can be combined, for compatibility with legacy tools while still future-proofing for when that compatibility is no longer needed. This third snippet again has the same outline as the previous two:

```
<body>
<h1>Let's call it a draw(ing surface)</h1>
<section>
<h2>Diving in</h2>
</section>
<section>
<h2>Simple shapes</h2>
</section>
<section>
<h2>Canvas coordinates</h2>
</section>
<section>
<h3>Canvas coordinates diagram</h3>
</section>
<section>
<h2>Paths</h2>
</section>
</body>
```

⋮

Spec bugs: [27117](#)

4.3.7 The `hgroup` element

Categories^{p113}:

- [Flow content](#)^{p115}.
- [Heading content](#)^{p116}.
- [Palpable content](#)^{p117}.

Contexts in which this element can be used^{p113}:

Where [flow content](#)^{p115} is expected.

Content model^{p113}:

One or more [h1](#)^{p168}, [h2](#)^{p168}, [h3](#)^{p168}, [h4](#)^{p168}, [h5](#)^{p168}, [h6](#)^{p168}, and [template](#)^{p604} elements.

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

- [Global attributes](#)^{p120}

DOM interface^{p113}:

Uses [HTMLElement](#)^{p112}.

The [hgroup](#)^{p170} element [represents](#)^{p111} the heading of a section, which consists of all the [h1](#)^{p168}–[h6](#)^{p168} element children of the [hgroup](#)^{p170} element. The element is used to group a set of [h1](#)^{p168}–[h6](#)^{p168} elements when the heading has multiple levels, such as subheadings, alternative titles, or taglines.

The [rank](#)^{p169} of an [hgroup](#)^{p170} element is the rank of the highest-ranked [h1](#)^{p168}–[h6](#)^{p168} element descendant of the [hgroup](#)^{p170} element, if there are any such elements, or otherwise the same as for an [h1](#)^{p168} element (the highest rank). Other elements of [heading content](#)^{p116} in the [hgroup](#)^{p170} element indicate subheadings or subtitles.

The section on [headings and sections](#)^{p176} defines how [hgroup](#)^{p170} elements are assigned to individual sections.

Example

Here are some examples of valid headings.

```
<hgroup>
  <h1>The reality dysfunction</h1>
  <h2>Space is not the only void</h2>
</hgroup>

<hgroup>
  <h1>Dr. Strangelove</h1>
  <h2>Or: How I Learned to Stop Worrying and Love the Bomb</h2>
</hgroup>
```

The point of using [hgroup](#)^{p170} in these examples is to mask the [h2](#)^{p168} element (which acts as a secondary title) from the [outline](#)^{p178} algorithm.

How a user agent exposes such multi-level headings in user interfaces (e.g. in tables of contents or search results) is left open to implementors, as it is a user interface issue. The first example above could be rendered as:

The reality dysfunction: Space is not the only void

Alternatively, it could look like this:

The reality dysfunction (Space is not the only void)

In interfaces where a title can be rendered on multiple lines, it could be rendered as follows, maybe with the first line in a bigger font size:

The reality dysfunction
Space is not the only void

Example

In the following example, an `hgroup`^{p170} element is used to mark up a two-level heading in a wizard-style dialog box:

```
<dialog onclose="walletSetup.continue(this.returnValue)">
  <hgroup>
    <h1>Wallet Setup</h1>
    <h2>Configure your Wallet funding source</h2>
  </hgroup>
  <p>Your Wallet can be used to buy wands at the merchant in town, to buy potions from travelling salesmen you may find in the dungeons, and to pay for mercenaries.</p>
  <p>We support two payment sources:</p>
  <form method=dialog>
    <fieldset oninput="this.getElementsByName('input')[0].checked = true">
      <legend> <label> <input type=radio name=payment-type value=cc> Credit Card </label> </legend>
      <p><label>Name on card: <input name=cc1 autocomplete="section-cc cc-name" placeholder="Y. Name"></label>
        <p><label>Card number: <input name=cc2 inputmode=numeric autocomplete="section-cc cc-number" placeholder="6331 1019 9999 0016"></label>
        <p><label>Expiry Date: <input name=cc3 type=month autocomplete="section-cc cc-exp" placeholder="2020-02"></label>
        <p><label>Security Code: <input name=cc4 inputmode=numeric autocomplete="section-cc cc-csc" placeholder="246"></label>
      </fieldset>
      <fieldset oninput="this.getElementsByName('input')[0].checked = true">
        <legend> <label> <input type=radio name=payment-type value=bank> Checking Account </label>
      </legend>
        <p><label>Name on account: <input name=bank1 autocomplete="section-bank cc-name"></label>
        <p><label>Routing number: <input name=bank2 inputmode=numeric></label>
        <p><label>Account number: <input name=bank3 inputmode=numeric></label>
      </fieldset>
      <button type=submit value="back"> ← Back </button>
      <button type=submit value="next"> Next → </button>
    </form>
  </dialog>
```

4.3.8 The `header` element

Categories^{p113}:

[Flow content](#)^{p115}.

[Palpable content](#)^{p117}.

Contexts in which this element can be used^{p113}:

Where [flow content](#)^{p115} is expected.

Content model^{p113}:

[Flow content](#)^{p115}, but with no [header](#)^{p171}, [footer](#)^{p173}, or [main](#)^{p205} element descendants.

Tag omission in text/html^{p113}:

Neither tag is ommissible.

Content attributes^{p113}:

[Global attributes](#)^{p120}

DOM interface^{p113}:

Uses [HTMLElement](#)^{p112}.

The `header`^{p171} element [represents](#)^{p111} a group of introductory or navigational aids.

Note A `header`^{p171} element is intended to usually contain the section's heading (an `h1`^{p166}-`h6`^{p168} element or an `hgroup`^{p170} element), but this is not required. The `header`^{p171} element can also be used to wrap a section's table of contents, a search form, or any relevant logos.

Example

Here are some sample headers. This first one is for a game:

```
<header>
<p>Welcome to...</p>
<h1>Voidwars!</h1>
</header>
```

The following snippet shows how the element can be used to mark up a specification's header:

```
<header>
<hgroup>
<h1>Scalable Vector Graphics (SVG) 1.2</h1>
<h2>W3C Working Draft 27 October 2004</h2>
</hgroup>
<dl>
<dt>This version:</dt>
<dd><a href="http://www.w3.org/TR/2004/WD-SVG12-20041027/">http://www.w3.org/TR/2004/
WD-SVG12-20041027/</a></dd>
<dt>Previous version:</dt>
<dd><a href="http://www.w3.org/TR/2004/WD-SVG12-20040510/">http://www.w3.org/TR/2004/
WD-SVG12-20040510/</a></dd>
<dt>Latest version of SVG 1.2:</dt>
<dd><a href="http://www.w3.org/TR/SVG12/">http://www.w3.org/TR/SVG12/</a></dd>
<dt>Latest SVG Recommendation:</dt>
<dd><a href="http://www.w3.org/TR/SVG/">http://www.w3.org/TR/SVG/</a></dd>
<dt>Editor:</dt>
<dd>Dean Jackson, W3C, <a href="mailto:dean@w3.org">dean@w3.org</a></dd>
<dt>Authors:</dt>
<dd>See <a href="#authors">Author List</a></dd>
</dl>
<p class="copyright"><a href="http://www.w3.org/Consortium/Legal/ipr-notice ...
</header>
```

Note The header^{p171} element is not sectioning content^{p116}; it doesn't introduce a new section.

Example

In this example, the page has a page heading given by the h1^{p168} element, and two subsections whose headings are given by h2^{p168} elements. The content after the header^{p171} element is still part of the last subsection started in the header^{p171} element, because the header^{p171} element doesn't take part in the outline^{p178} algorithm.

```
<body>
<header>
<h1>Little Green Guys With Guns</h1>
<nav>
<ul>
<li><a href="/games">Games</a>
<li><a href="/forum">Forum</a>
<li><a href="/download">Download</a>
</ul>
</nav>
<h2>Important News</h2> <!-- this starts a second subsection -->
<!-- this is part of the subsection entitled "Important News" -->
<p>To play today's games you will need to update your client.</p>
<h2>Games</h2> <!-- this starts a third subsection -->
</header>
<p>You have three active games:</p>
<!-- this is still part of the subsection entitled "Games" -->
...
...
```

4.3.9 The `footer` element

Categories^{p113}:

[Flow content](#)^{p115}.
[Palpable content](#)^{p117}.

Contexts in which this element can be used^{p113}:

Where [flow content](#)^{p115} is expected.

Content model^{p113}:

[Flow content](#)^{p115}, but with no [header](#)^{p171}, [footer](#)^{p173}, or [main](#)^{p205} element descendants.

Tag omission in text/html^{p113}:

Neither tag is ommissible.

Content attributes^{p113}:

[Global attributes](#)^{p120}

DOM interface^{p113}:

Uses [HTMLElement](#)^{p112}.

The [footer](#)^{p173} element [represents](#)^{p111} a footer for its nearest ancestor [sectioning content](#)^{p116} or [sectioning root](#)^{p176} element. A footer typically contains information about its section such as who wrote it, links to related documents, copyright data, and the like.

When the [footer](#)^{p173} element contains entire sections, they [represent](#)^{p111} appendices, indexes, long colophons, verbose license agreements, and other such content.

Note *Contact information for the author or editor of a section belongs in an [address](#)^{p175} element, possibly itself inside a [footer](#)^{p173}. Bylines and other information that could be suitable for both a [header](#)^{p171} or a [footer](#)^{p173} can be placed in either (or neither). The primary purpose of these elements is merely to help the author write self-explanatory markup that is easy to maintain and style; they are not intended to impose specific structures on authors.*

Footers don't necessarily have to appear at the end of a section, though they usually do.

When the nearest ancestor [sectioning content](#)^{p116} or [sectioning root](#)^{p176} element is the [body element](#)^{p106}, then it applies to the whole page.

Note *The [footer](#)^{p173} element is not [sectioning content](#)^{p116}; it doesn't introduce a new section.*

Example

Here is a page with two footers, one at the top and one at the bottom, with the same content:

```
<body>
  <footer><a href="#">Back to index...</a></footer>
  <hgroup>
    <h1>Lorem ipsum</h1>
    <h2>The ipsum of all lorem</h2>
  </hgroup>
  <p>A dolor sit amet, consectetur adipisicing elit, sed do eiusmod
  tempor incididunt ut labore et dolore magna aliqua. Ut enim ad minim
  veniam, quis nostrud exercitation ullamco laboris nisi ut aliquip ex
  ea commodo consequat. Duis aute irure dolor in reprehenderit in
  voluptate velit esse cillum dolore eu fugiat nulla
  pariatur. Excepteur sint occaecat cupidatat non proident, sunt in
  culpa qui officia deserunt mollit anim id est laborum.</p>
  <footer><a href="#">Back to index...</a></footer>
</body>
```

Example

Here is an example which shows the [footer](#)^{p173} element being used both for a site-wide footer and for a section footer.

```
<!DOCTYPE HTML>
<HTML><HEAD>
  <TITLE>The Ramblings of a Scientist</TITLE>
<BODY>
```

```

<H1>The Ramblings of a Scientist</H1>
<ARTICLE>
  <H1>Episode 15</H1>
  <VIDEO SRC="/fm/015.ogv" CONTROLS PRELOAD>
    <P><A HREF="/fm/015.ogv">Download video</A>.</P>
  </VIDEO>
  <FOOTER> <!-- footer for article -->
    <P>Published <TIME DATETIME="2009-10-21T18:26-07:00">on 2009/10/21 at 6:26pm</TIME></P>
  </FOOTER>

</FOOTER>
</BODY>
</HTML>

```

Example

Some site designs have what is sometimes referred to as "fat footers" — footers that contain a lot of material, including images, links to other articles, links to pages for sending feedback, special offers... in some ways, a whole "front page" in the footer.

This fragment shows the bottom of a page on a site with a "fat footer":

```

...
<footer>
  <nav>
    <section>
      <h1>Articles</h1>
      <p> Go to the gym with
our somersaults class! Our teacher Jim takes you through the paces
in this two-part article. <a href="articles/somersaults/1">Part
1</a> · <a href="articles/somersaults/2">Part 2</a></p>
      <p> Tired of walking on the edge of
a cliff! -- sic --? Our guest writer Lara shows you how to bumble
your way through the bars. <a href="articles/kindplus/1">Read
more...</a></p>
      <p> The chips are down, now all
that's left is a potato. What can you do with it? <a
href="articles/crisps/1">Read more...</a></p>
    </section>
    <ul>
      <li> <a href="/about">About us...</a>
      <li> <a href="/feedback">Send feedback!</a>
      <li> <a href="/sitemap">Sitemap</a>
    </ul>
  </nav>
  <p><small>Copyright & 2015 The Snacker -
    <a href="/tos">Terms of Service</a></small></p>

```

```
</footer>  
</body>
```

4.3.10 The `address` element

Categories^{p113}:

[Flow content](#)^{p115}.

[Palpable content](#)^{p117}.

Contexts in which this element can be used^{p113}:

Where [flow content](#)^{p115} is expected.

Content model^{p113}:

[Flow content](#)^{p115}, but with no [heading content](#)^{p116} descendants, no [sectioning content](#)^{p116} descendants, and no [header](#)^{p171}, [footer](#)^{p173}, or [address](#)^{p175} element descendants.

Tag omission in text/html^{p113}:

Neither tag is ommissible.

Content attributes^{p113}:

[Global attributes](#)^{p120}

DOM interface^{p113}:

Uses [HTMLElement](#)^{p112}.

The [address](#)^{p175} element [represents](#)^{p111} the contact information for its nearest [article](#)^{p159} or [body](#)^{p157} element ancestor. If that is [the body element](#)^{p106}, then the contact information applies to the document as a whole.

Example

For example, a page at the W3C Web site related to HTML might include the following contact information:

```
<ADDRESS>  
  <A href="/People/Raggett/">Dave Raggett</A>,  
  <A href="/People/Arnaud/">Arnaud Le Hors</A>,  
  contact persons for the <A href="Activity">W3C HTML Activity</A>  
</ADDRESS>
```

The [address](#)^{p175} element must not be used to represent arbitrary addresses (e.g. postal addresses), unless those addresses are in fact the relevant contact information. (The [p](#)^{p187} element is the appropriate element for marking up postal addresses in general.)

The [address](#)^{p175} element must not contain information other than contact information.

Example

For example, the following is non-conforming use of the [address](#)^{p175} element:

```
<ADDRESS>Last Modified: 1999/12/24 23:37:50</ADDRESS>
```

Typically, the [address](#)^{p175} element would be included along with other information in a [footer](#)^{p173} element.

The contact information for a node *node* is a collection of [address](#)^{p175} elements defined by the first applicable entry from the following list:

↪ If *node* is an [article](#)^{p159} element

↪ If *node* is a [body](#)^{p157} element

The contact information consists of all the [address](#)^{p175} elements that have *node* as an ancestor and do not have another [body](#)^{p157} or [article](#)^{p159} element ancestor that is a descendant of *node*.

↪ If *node* has an ancestor element that is an [article](#)^{p159} element

↪ If *node* has an ancestor element that is a [body](#)^{p157} element

The contact information of *node* is the same as the contact information of the nearest [article](#)^{p159} or [body](#)^{p157} element ancestor, whichever is nearest.

↪ If *node*'s [node document](#) has a [body element](#)^{p106}

The contact information of *node* is the same as the contact information of [the body element](#)^{p106} of the [Document](#)^{p102}.

↪ Otherwise

There is no contact information for *node*.

User agents may expose the contact information of a node to the user, or use it for other purposes, such as indexing sections based on the sections' contact information.

Example

In this example the footer contains contact information and a copyright notice.

```
<footer>
  <address>
    For more details, contact
    <a href="mailto:js@example.com">John Smith</a>.
  </address>
  <p><small>© copyright 2038 Example Corp.</small></p>
</footer>
```

4.3.11 Headings and sections

The [h1](#)^{p168}–[h6](#)^{p168} elements and the [hgroup](#)^{p170} element are headings.

The first element of [heading content](#)^{p116} in an element of [sectioning content](#)^{p116} represents^{p111} the heading for that section. Subsequent headings of equal or higher [rank](#)^{p169} start new (implied) sections, headings of lower [rank](#)^{p169} start implied subsections that are part of the previous one. In both cases, the element represents^{p111} the heading of the implied section.

Certain elements are said to be **sectioning roots**, including [blockquote](#)^{p193} and [td](#)^{p412} elements. These elements can have their own outlines, but the sections and headings inside these elements do not contribute to the outlines of their ancestors.

⇒ [blockquote](#)^{p193}, [body](#)^{p157}, [details](#)^{p567}, [dialog](#)^{p586}, [fieldset](#)^{p524}, [figure](#)^{p202}, [td](#)^{p412}

[Sectioning content](#)^{p116} elements are always considered subsections of their nearest ancestor [sectioning root](#)^{p176} or their nearest ancestor element of [sectioning content](#)^{p116}, whichever is nearest, regardless of what implied sections other headings may have created.

Example

For the following fragment:

```
<body>
  <h1>Foo</h1>
  <h2>Bar</h2>
  <blockquote>
    <h3>Bla</h3>
  </blockquote>
  <p>Baz</p>
  <h2>Quux</h2>
  <section>
    <h3>Thud</h3>
  </section>
  <p>Grunt</p>
</body>
```

...the structure would be:

1. Foo (heading of explicit [body](#)^{p157} section, containing the "Grunt" paragraph)
 1. Bar (heading starting implied section, containing a block quote and the "Baz" paragraph)
 2. Quux (heading starting implied section with no content other than the heading itself)
 3. Thud (heading of explicit [section](#)^{p161} section)

Notice how the [section^{p161}](#) ends the earlier implicit section so that a later paragraph ("Grunt") is back at the top level.

Sections may contain headings of any [rank^{p169}](#), but authors are strongly encouraged to either use only [h1^{p168}](#) elements, or to use elements of the appropriate [rank^{p169}](#) for the section's nesting level.

Authors are also encouraged to explicitly wrap sections in elements of [sectioning content^{p116}](#), instead of relying on the implicit sections generated by having multiple headings in one element of [sectioning content^{p116}](#).

Example

For example, the following is correct:

```
<body>
  <h4>Apples</h4>
  <p>Apples are fruit.</p>
  <section>
    <h2>Taste</h2>
    <p>They taste lovely.</p>
    <h6>Sweet</h6>
    <p>Red apples are sweeter than green ones.</p>
    <h1>Colour</h1>
    <p>Apples come in various colours.</p>
  </section>
</body>
```

However, the same document would be more clearly expressed as:

```
<body>
  <h1>Apples</h1>
  <p>Apples are fruit.</p>
  <section>
    <h2>Taste</h2>
    <p>They taste lovely.</p>
    <section>
      <h3>Sweet</h3>
      <p>Red apples are sweeter than green ones.</p>
    </section>
  </section>
  <section>
    <h2>Colour</h2>
    <p>Apples come in various colours.</p>
  </section>
</body>
```

Both of the documents above are semantically identical and would produce the same outline in compliant user agents.

This third example is also semantically identical, and might be easier to maintain (e.g. if sections are often moved around in editing):

```
<body>
  <h1>Apples</h1>
  <p>Apples are fruit.</p>
  <section>
    <h1>Taste</h1>
    <p>They taste lovely.</p>
    <section>
      <h1>Sweet</h1>
      <p>Red apples are sweeter than green ones.</p>
    </section>
  </section>
  <section>
    <h1>Colour</h1>
    <p>Apples come in various colours.</p>
  </section>
```

```
</section>  
</body>
```

This final example would need explicit style rules to be rendered well in legacy browsers. Legacy browsers without CSS support would render all the headings as top-level headings.

4.3.11.1 Creating an outline

This section defines an algorithm for creating an outline for a [sectioning content^{p116}](#) element or a [sectioning root^{p176}](#) element. It is defined in terms of a walk over the nodes of a DOM tree, in [tree order^{p42}](#), with each node being visited when it is *entered* and when it is *exited* during the walk.

The **outline** for a [sectioning content^{p116}](#) element or a [sectioning root^{p176}](#) element consists of a list of one or more potentially nested [sections^{p178}](#). The element for which an [outline^{p178}](#) is created is said to be **the outline's owner**.

A **section** is a container that corresponds to some nodes in the original DOM tree. Each section can have one heading associated with it, and can contain any number of further nested sections. The algorithm for the outline also associates each node in the DOM tree with a particular section and potentially a heading. (The sections in the outline aren't [section^{p161}](#) elements, though some may correspond to such elements — they are merely conceptual sections.)

Example

The following markup fragment:

```
<body>  
  <h1>A</h1>  
  <p>B</p>  
  <h2>C</h2>  
  <p>D</p>  
  <h2>E</h2>  
  <p>F</p>  
</body>
```

...results in the following outline being created for the [body^{p157}](#) node (and thus the entire document):

1. Section created for [body^{p157}](#) node.
Associated with heading "A".
Also associated with paragraph "B".
Nested sections:
 1. Section implied for first [h2^{p168}](#) element.
Associated with heading "C".
Also associated with paragraph "D".
No nested sections.
 2. Section implied for second [h2^{p168}](#) element.
Associated with heading "E".
Also associated with paragraph "F".
No nested sections.

The algorithm that must be followed during a walk of a DOM subtree rooted at a [sectioning content^{p116}](#) element or a [sectioning root^{p176}](#) element to determine that element's [outline^{p178}](#) is as follows:

1. Let *current outline target* be null. (It holds the element whose [outline^{p178}](#) is being created.)
2. Let *current section* be null. (It holds a pointer to a [section^{p178}](#), so that elements in the DOM can all be associated with a section.)
3. Create a stack to hold elements, which is used to handle nesting. Initialise this stack to empty.
4. Walk over the DOM in [tree order^{p42}](#), starting with the [sectioning content^{p116}](#) element or [sectioning root^{p176}](#) element at the root of the subtree for which an outline is to be created, and trigger the first relevant step below for each element as the walk enters and exits it.

↪ When exiting an element, if that element is the element at the top of the stack

Note *The element being exited is a [heading content^{p116}](#) element or an element with a [hidden^{p723}](#) attribute.*

Pop that element from the stack.

↪ If the top of the stack is a [heading content^{p116}](#) element or an element with a [hidden^{p723}](#) attribute

Do nothing.

↪ When entering an element with a [hidden^{p723}](#) attribute

Push the element being entered onto the stack. (This causes the algorithm to skip that element and any descendants of the element.)

↪ When entering a [sectioning content^{p116}](#) element

Run these steps:

1. If *current outline target* is not null, run these substeps:
 1. If the *current section* has no heading, create an implied heading and let that be the heading for the *current section*.
 2. Push *current outline target* onto the stack.
2. Let *current outline target* be the element that is being entered.
3. Let *current section* be a newly created [section^{p178}](#) for the *current outline target* element.
4. Associate *current outline target* with *current section*.
5. Let there be a new [outline^{p178}](#) for the new *current outline target*, initialised with just the new *current section* as the only [section^{p178}](#) in the outline.

↪ When exiting a [sectioning content^{p116}](#) element, if the stack is not empty

Run these steps:

1. If the *current section* has no heading, create an implied heading and let that be the heading for the *current section*.
2. Pop the top element from the stack, and let the *current outline target* be that element.
3. Let *current section* be the last section in the [outline^{p178}](#) of the *current outline target* element.
4. Append the [outline^{p178}](#) of the [sectioning content^{p116}](#) element being exited to the *current section*. (This does not change which section is the last section in the [outline^{p178}](#).)

↪ When entering a [sectioning root^{p176}](#) element

Run these steps:

1. If *current outline target* is not null, push *current outline target* onto the stack.
2. Let *current outline target* be the element that is being entered.
3. Let *current outline target's parent section* be *current section*.
4. Let *current section* be a newly created [section^{p178}](#) for the *current outline target* element.
5. Let there be a new [outline^{p178}](#) for the new *current outline target*, initialised with just the new *current section* as the only [section^{p178}](#) in the outline.

↪ When exiting a [sectioning root^{p176}](#) element, if the stack is not empty

Run these steps:

1. If the *current section* has no heading, create an implied heading and let that be the heading for the *current section*.
2. Let *current section* be *current outline target's parent section*.
3. Pop the top element from the stack, and let the *current outline target* be that element.

↪ When exiting a [sectioning content^{p116}](#) element or a [sectioning root^{p176}](#) element (when the stack is empty)

Note The current outline target is the element being exited, and it is the [sectioning content^{p116}](#) element or a [sectioning root^{p176}](#) element at the root of the subtree for which an outline is being generated.

If the *current section* has no heading, create an implied heading and let that be the heading for the *current section*.

Skip to the next step in the overall set of steps. (The walk is over.)

↪ When entering a [heading content^{p116}](#) element

If the *current section* has no heading, let the element being entered be the heading for the *current section*.

Otherwise, if the element being entered has a [rank^{p169}](#) equal to or higher than the heading of the last section of the [outline^{p178}](#) of the *current outline target*, or if the heading of the last section of the [outline^{p178}](#) of the *current outline target* is an implied heading, then create a new [section^{p178}](#) and append it to the [outline^{p178}](#) of the *current outline target* element, so that this new section is the new last section of that outline. Let *current section* be that new section. Let the element being entered be the new heading for the *current section*.

Otherwise, run these substeps:

1. Let *candidate section* be *current section*.
2. *Heading loop*: If the element being entered has a [rank^{p169}](#) lower than the [rank^{p169}](#) of the heading of the *candidate section*, then create a new [section^{p178}](#), and append it to *candidate section*. (This does not change which section is the last section in the outline.) Let *current section* be this new section. Let the element being entered be the new heading for the *current section*. Abort these substeps.
3. Let *new candidate section* be the [section^{p178}](#) that contains *candidate section* in the [outline^{p178}](#) of *current outline target*.
4. Let *candidate section* be *new candidate section*.
5. Return to the step labeled *heading loop*.

Push the element being entered onto the stack. (This causes the algorithm to skip any descendants of the element.)

Note Recall that [h1^{p168}](#) has the highest rank, and [h6^{p168}](#) has the lowest rank.

↪ Otherwise

Do nothing.

In addition, whenever the walk exits a node, after doing the steps above, if the node is not associated with a [section^{p178}](#) yet, associate the node with the [section^{p178}](#) *current section*.

5. Associate all non-element nodes that are in the subtree for which an outline is being created with the [section^{p178}](#) with which their parent element is associated.
6. Associate all nodes in the subtree with the heading of the [section^{p178}](#) with which they are associated, if any.

The tree of sections created by the algorithm above, or a proper subset thereof, must be used when generating document outlines, for example when generating tables of contents.

The outline created for [the body element^{p106}](#) of a [Document^{p102}](#) is the [outline^{p178}](#) of the entire document.

When creating an interactive table of contents, entries should jump the user to the relevant [sectioning content^{p116}](#) element, if the [section^{p178}](#) was created for a real element in the original document, or to the relevant [heading content^{p116}](#) element, if the [section^{p178}](#) in the tree was generated for a heading in the above process.

Note Selecting the first [section^{p178}](#) of the document therefore always takes the user to the top of the document, regardless of where the first heading in the [body^{p157}](#) is to be found.

The **outline depth** of a [heading content^{p116}](#) element associated with a [section^{p178}](#) *section* is the number of [sections^{p178}](#) that are ancestors of *section* in the outermost [outline^{p178}](#) that *section* finds itself in when the [outlines^{p178}](#) of its [Document^{p102}](#)'s elements are created, plus 1. The [outline depth^{p180}](#) of a [heading content^{p116}](#) element not associated with a [section^{p178}](#) is 1.

User agents should provide default headings for sections that do not have explicit section headings.

Example

Consider the following snippet:

```
<body>
<nav>
<p><a href="/">Home</a></p>
```

```

</nav>
<p>Hello world.</p>
<aside>
  <p>My cat is cute.</p>
</aside>
</body>

```

Although it contains no headings, this snippet has three sections: a document (the [body^{p157}](#)) with two subsections (a [nav^{p163}](#) and an [aside^{p166}](#)). A user agent could present the outline as follows:

1. Untitled document
 1. Navigation
 2. Sidebar

These default headings ("Untitled document", "Navigation", "Sidebar") are not specified by this specification, and might vary with the user's language, the page's language, the user's preferences, the user agent implementor's preferences, etc.

Note *The following JavaScript function shows how the tree walk could be implemented. The root argument is the root of the tree to walk (either a [sectioning content^{p116}](#) element or a [sectioning root^{p176}](#) element), and the enter and exit arguments are callbacks that are called with the nodes as they are entered and exited. [\[ECMA262\]^{p150}](#)*

```

function (root, enter, exit) {
  var node = root;
  start: while (node) {
    enter(node);
    if (node.firstChild) {
      node = node.firstChild;
      continue start;
    }
    while (node) {
      exit(node);
      if (node == root) {
        node = null;
      } else if (node.nextSibling) {
        node = node.nextSibling;
        continue start;
      } else {
        node = node.parentNode;
      }
    }
  }
}

```

4.3.11.2 Sample outlines

This section is non-normative.

Example

The following document shows a straight-forward application of the [outline^{p178}](#) algorithm. First, here is the document, which is a book with very short chapters and subsections:

```

<!DOCTYPE HTML>
<title>The Tax Book (all in one page)</title>
<h1>The Tax Book</h1>
<h2>Earning money</h2>
<p>Earning money is good.</p>
<h3>Getting a job</h3>
<p>To earn money you typically need a job.</p>
<h2>Spending money</h2>
<p>Spending is what money is mainly used for.</p>
<h3>Cheap things</h3>

```

```

<p>Buying cheap things often not cost-effective.</p>
<h3>Expensive things</h3>
<p>The most expensive thing is often not the most cost-effective either.</p>
<h2>Investing money</h2>
<p>You can lend your money to other people.</p>
<h2>Losing money</h2>
<p>If you spend money or invest money, sooner or later you will lose money.
<h3>Poor judgement</h3>
<p>Usually if you lose money it's because you made a mistake.</p>

```

This book would form the following outline:

1. The Tax Book
 1. Earning money
 1. Getting a job
 2. Spending money
 1. Cheap things
 2. Expensive things
 3. Investing money
 4. Losing money
 1. Poor judgement

Notice that the [title](#)^{p139} element does not participate in the outline.

Example

Here is a similar document, but this time using [section](#)^{p161} elements to get the same effect:

```

<!DOCTYPE HTML>
<title>The Tax Book (all in one page)</title>
<h1>The Tax Book</h1>
<section>
  <h1>Earning money</h1>
  <p>Earning money is good.</p>
<section>
  <h1>Getting a job</h1>
  <p>To earn money you typically need a job.</p>
</section>
</section>
<section>
  <h1>Spending money</h1>
  <p>Spending is what money is mainly used for.</p>
<section>
  <h1>Cheap things</h1>
  <p>Buying cheap things often not cost-effective.</p>
</section>
<section>
  <h1>Expensive things</h1>
  <p>The most expensive thing is often not the most cost-effective either.</p>
</section>
</section>
<section>
  <h1>Investing money</h1>
  <p>You can lend your money to other people.</p>
</section>
<section>
  <h1>Losing money</h1>
  <p>If you spend money or invest money, sooner or later you will lose money.
<section>
  <h1>Poor judgement</h1>
  <p>Usually if you lose money it's because you made a mistake.</p>
</section>
</section>

```

This book would form the same outline:

1. The Tax Book
 1. Earning money
 1. Getting a job
 2. Spending money
 1. Cheap things
 2. Expensive things
 3. Investing money
 4. Losing money
 1. Poor judgement

Example

A document can contain multiple top-level headings:

```
<!DOCTYPE HTML>
<title>Alphabetic Fruit</title>
<h1>Apples</h1>
<p>Pomaceous.</p>
<h1>Bananas</h1>
<p>Edible.</p>
<h1>Carambola</h1>
<p>Star.</p>
```

This would form the following simple outline consisting of three top-level sections:

1. Apples
2. Bananas
3. Carambola

Effectively, the body^{p157} element is split into three.

Example

Mixing both the h1^{p168}-h6^{p168} model and the section^{p161}/h1^{p168} model can lead to some unintuitive results.

Consider for example the following, which is just the previous example but with the contents of the (implied) body^{p157} wrapped in a section^{p161}.

```
<!DOCTYPE HTML>
<title>Alphabetic Fruit</title>
<section>
  <h1>Apples</h1>
  <p>Pomaceous.</p>
  <h1>Bananas</h1>
  <p>Edible.</p>
  <h1>Carambola</h1>
  <p>Star.</p>
</section>
```

The resulting outline would be:

1. (*untitled page*)
 1. Apples
 2. Bananas
 3. Carambola

This result is described as *unintuitive* because it results in three subsections even though there's only one section^{p161} element.

Effectively, the section^{p161} is split into three, just like the implied body^{p157} element in the previous example.

(In this example, "(*untitled page*)" is the implied heading for the body^{p157} element, since it has no explicit heading.)

Example

Headings never rise above other sections. Thus, in the following example, the first h1^{p168} does not actually describe the page header; it describes the header for the second half of the page:

```
<!DOCTYPE HTML>
<title>Feathers on The Site of Encyclopedic Knowledge</title>
<section>
  <h1>A plea from our caretakers</h1>
```

```

<p>Please, we beg of you, send help! We're stuck in the server room!</p>
</section>
<h1>Feathers</h1>
<p>Epidermal growths.</p>

```

The resulting outline would be:

1. (*untitled page*)
 1. A plea from our caretakers
2. Feathers

Example

Thus, when an [article](#)^{p159} element starts with a [nav](#)^{p163} block and only later has its heading, the result is that the [nav](#)^{p163} block is not part of the same section as the rest of the [article](#)^{p159} in the outline. For instance, take this document:

```

<!DOCTYPE HTML>
<title>We're adopting a child! – Ray's blog</title>
<h1>Ray's blog</h1>
<article>
  <header>
    <nav>
      <a href="?t=-1d">Yesterday</a>;
      <a href="?t=-7d">Last week</a>;
      <a href="?t=-1m">Last month</a>
    </nav>
    <h1>We're adopting a child!</h1>
  </header>
  <main>
    <p>As of today, Janine and I have signed the papers to become
    the proud parents of baby Diane! We've been looking forward to
    this day for weeks.</p>
  </main>
</article>

```

The resulting outline would be:

1. Ray's blog
 1. *Untitled article*
 1. *Untitled navigation section*
 2. We're adopting a child!

Also worthy of note in this example is that the [header](#)^{p171} and [main](#)^{p205} elements have no effect whatsoever on the document outline.

Example

The [hgroup](#)^{p170} element can be used for subheadings. For example:

```

<!DOCTYPE HTML>
<title>Chronotype: CS Student</title>
<hgroup>
  <h1> The morning </h1>
  <h2> 06:00 to 12:00 </h2>
</hgroup>
<p>We sleep.</p>
<hgroup>
  <h1> The afternoon </h1>
  <h2> 12:00 to 18:00 </h2>
</hgroup>
<p>We study.</p>
<hgroup>
  <h2>Additional Commentary</h2>
  <h3>Because not all this is necessarily true</h3>
  <h6>Ok it's almost certainly not true</h6>
</hgroup>
<p>Yeah we probably play, rather than study.</p>

```

```

<hgroup>
  <h1> The evening </h1>
  <h2> 18:00 to 00:00 </h2>
</hgroup>
<p>We play.</p>
<hgroup>
  <h1> The night </h1>
  <h2> 00:00 to 06:00 </h2>
</hgroup>
<p>We play some more.</p>

```

The resulting outline would be:

1. The morning 06:00 to 12:00
2. The afternoon 12:00 to 18:00
 1. Additional Commentary Because not all this is necessarily true Ok it's almost certainly not true
3. The evening 18:00 to 00:00
4. The night 00:00 to 06:00

Exactly how this is represented by user agents, as most interface issues, is left as a matter of implementation preference, but the key part is that the [hgroup^{p170}](#)'s descendant [h1^{p168}](#)-[h6^{p168}](#) elements are what form the element's heading. Thus, the following would be equally valid:

1. The morning — 06:00 to 12:00
2. The afternoon — 12:00 to 18:00
 1. Additional Commentary — Because not all this is necessarily true — Ok it's almost certainly not true
3. The evening — 18:00 to 00:00
4. The night — 00:00 to 06:00

But so would the following:

1. The morning
2. The afternoon
 1. Additional Commentary
3. The evening
4. The night

The following would also be valid, though maybe less practical in most contexts:

1. The morning
 - 06:00 to 12:00
2. The afternoon
 - 12:00 to 18:00
 1. Additional Commentary

Because not all this is necessarily true
Ok it's almost certainly not true
3. The evening
 - 18:00 to 00:00
4. The night
 - 00:00 to 06:00

4.3.11.3 Exposing outlines to users

User agents are encouraged to expose page outlines to users to aid in navigation. This is especially true for non-visual media, e.g. screen readers.

However, to mitigate the difficulties that arise from authors misusing [sectioning content^{p116}](#), user agents are also encouraged to offer a mode that navigates the page using [heading content^{p116}](#) alone.

Example

For instance, a user agent could map the arrow keys as follows:

Shift+← Left

Go to previous section, including subsections of previous sections

Shift+→ Right

Go to next section, including subsections of the current section

Shift+↑ Up

Go to parent section of the current section

Shift+↓ Down

Go to next section, skipping subsections of the current section

Plus in addition, the user agent could map the **j** and **k** keys to navigating to the previous or next element of [heading content^{p116}](#), regardless of the section's outline depth and ignoring sections with no headings.

4.3.12 Usage summary

This section is non-normative.

Element	Purpose
Element	Example
body^{p157}	<p>The main content of the document.</p> <pre data-bbox="251 642 816 777"><!DOCTYPE HTML> <html> <head> <title>Steve Hill's Home Page</title> </head> <body> <p>Hard Trance is My Life.</p> </body> </html></pre>
article^{p159}	<p>A complete, or self-contained, composition in a document, page, application, or site and that is, in principle, independently distributable or reusable, e.g. in syndication. This could be a forum post, a magazine or newspaper article, a blog entry, a user-submitted comment, an interactive widget or gadget, or any other independent item of content.</p> <pre data-bbox="251 874 1305 1127"><article> <p>My fave Masif tee so far!</p> <footer>Posted 2 days ago</footer> </article> <article> <p>Happy 2nd birthday Masif Saturdays!!!</p> <footer>Posted 3 weeks ago</footer> </article></pre>
section^{p161}	<p>A generic section of a document or application. A section, in this context, is a thematic grouping of content, typically with a heading.</p> <pre data-bbox="251 1170 636 1402"><h1>Biography</h1> <section> <h1>The facts</h1> <p>1500+ shows, 14+ countries</p> </section> <section> <h1>2010/2011 figures per year</h1> <p>100+ shows, 8+ countries</p> </section></pre>
nav^{p163}	<p>A section of a page that links to other pages or to parts within the page: a section with navigation links.</p> <pre data-bbox="251 1444 649 1564"><nav> <p>Home <p>Bio <p>Discog </nav></pre>
aside^{p166}	<p>A section of a page that consists of content that is tangentially related to the content around the aside^{p166} element, and which could be considered separate from that content. Such sections are often represented as sidebars in printed typography.</p> <pre data-bbox="251 1628 1498 1733"><h1>Music</h1> <p>As any burner can tell you, the event has a lot of trance.</p> <aside>You can buy the music we played at our playlist page. </aside> <p>This year we played a kind of trance that originated in Belgium, Germany, and the Netherlands in the mid 90s.</p></pre>
h1^{p168}–h6^{p168}	<p>A section heading</p> <pre data-bbox="251 1765 894 1902"><h1>The Guide To Music On The Playa</h1> <h2>The Main Stage</h2> <p>If you want to play on a stage, you should bring one.</p> <h2>Amplified Music</h2> <p>Amplifiers up to 300W or 90dB are welcome.</p></pre>
hgroup^{p170}	<p>The heading of a section, which consists of all the h1^{p168}–h6^{p168} element children of the hgroup^{p170} element. The element is used to group a set of h1^{p168}–h6^{p168} elements when the heading has multiple levels, such as subheadings, alternative titles, or taglines.</p>

Element	Purpose	Example
		<pre><hgroup> <h1>Burning Music</h1> <h2>The Guide To Music On The Playa</h2> </hgroup> <section> <hgroup> <h1>Main Stage</h1> <h2>The Fiction Of A Music Festival</h2> </hgroup> <p>If you want to play on a stage, you should bring one.</p> </section> <section> <hgroup> <h1>Loudness!</h1> <h2>Questions About Amplified Music</h2> </hgroup> <p>Amplifiers up to 300W or 90dB are welcome.</p> </section></pre>
header ^{p171}	A group of introductory or navigational aids.	<pre><article> <header> <h1>Hard Trance is My Life</h1> <p>By DJ Steve Hill and Technikal</p> </header> <p>The album with the amusing punctuation has red artwork.</p> </article></pre>
footer ^{p173}	A footer for its nearest ancestor sectioning content ^{p116} or sectioning root ^{p176} element. A footer typically contains information about its section such as who wrote it, links to related documents, copyright data, and the like.	<pre><article> <h1>Hard Trance is My Life</h1> <p>The album with the amusing punctuation has red artwork.</p> <footer> <p>Artists: DJ Steve Hill and Technikal</p> </footer> </article></pre>

4.3.12.1 Article or section?

This section is non-normative.

A [section](#)^{p161} forms part of something else. An [article](#)^{p159} is its own thing. But how does one know which is which? Mostly the real answer is "it depends on author intent".

For example, one could imagine a book with a "Granny Smith" chapter that just said "These juicy, green apples make a great filling for apple pies."; that would be a [section](#)^{p161} because there'd be lots of other chapters on (maybe) other kinds of apples.

On the other hand, one could imagine a tweet or reddit comment or tumblr post or newspaper classified ad that just said "Granny Smith. These juicy, green apples make a great filling for apple pies."; it would then be [article](#)^{p159}s because that was the whole thing.

A comment on an article is not part of the [article](#)^{p159} on which it is commenting, therefore it is its own [article](#)^{p159}.

4.4 Grouping content

4.4.1 The [p](#) element

Categories^{p113}:

[Flow content](#)^{p115}.

[Palpable content](#)^{p117}.

Contexts in which this element can be used^{p113}:

Where [flow content](#)^{b115} is expected.

Content model^{p113}:

[Phrasing content](#)^{p116}.

Tag omission in text/html^{p113}:

A [p](#)^{p187} element's [end tag](#)^{p944} can be omitted if the [p](#)^{p187} element is immediately followed by an [address](#)^{p175}, [article](#)^{p159}, [aside](#)^{p166}, [blockquote](#)^{p193}, [details](#)^{p567}, [div](#)^{p207}, [dl](#)^{p199}, [fieldset](#)^{p524}, [figcaption](#)^{p205}, [figure](#)^{p202}, [footer](#)^{p173}, [form](#)^{p447}, [h1](#)^{p168}, [h2](#)^{p168}, [h3](#)^{p168}, [h4](#)^{p168}, [h5](#)^{p168}, [h6](#)^{p168}, [header](#)^{p171}, [hgroup](#)^{p170}, [hr](#)^{p190}, [main](#)^{p205}, [menu](#)^{p571}, [nav](#)^{p163}, [ol](#)^{p195}, [p](#)^{p187}, [pre](#)^{p191}, [section](#)^{p161}, [table](#)^{p398}, or [ul](#)^{p197}, element, or if there is no more content in the parent element and the parent element is an [HTML element](#)^{b42} that is not an [a](#)^{p208}, [audio](#)^{p321}, [del](#)^{p262}, [ins](#)^{p260}, [map](#)^{p389}, [noscript](#)^{p602}, or [video](#)^{p317} element.

Content attributes^{p113}:

[Global attributes](#)^{p120}

DOM interface^{p113}:

```
IDL interface HTMLParagraphElement : HTMLElement {
    // also has obsolete members
};
```

The [p](#)^{p187} element [represents](#)^{p111} a [paragraph](#)^{p118}.

Note While paragraphs are usually represented in visual media by blocks of text that are physically separated from adjacent blocks through blank lines, a style sheet or user agent would be equally justified in presenting paragraph breaks in a different manner, for instance using inline pilcrows (¶).

Example

The following examples are conforming HTML fragments:

```
<p>The little kitten gently seated himself on a piece of
carpet. Later in his life, this would be referred to as the time the
cat sat on the mat.</p>

<fieldset>
  <legend>Personal information</legend>
  <p>
    <label>Name: <input name="n"></label>
    <label><input name="anon" type="checkbox"> Hide from other users</label>
  </p>
  <p><label>Address: <textarea name="a"></textarea></label></p>
</fieldset>

<p>There was once an example from Femley,<br>
Whose markup was of dubious quality.<br>
The validator complained,<br>
So the author was pained,<br>
To move the error from the markup to the rhyming.</p>
```

The [p](#)^{p187} element should not be used when a more specific element is more appropriate.

Example

The following example is technically correct:

```
<section>
  <!-- ... -->
  <p>Last modified: 2001-04-23</p>
  <p>Author: fred@example.com</p>
</section>
```

However, it would be better marked-up as:

```
<section>
<!-- ... -->
<footer>Last modified: 2001-04-23</footer>
<address>Author: fred@example.com</address>
</section>
```

Or:

```
<section>
<!-- ... -->
<footer>
<p>Last modified: 2001-04-23</p>
<address>Author: fred@example.com</address>
</footer>
</section>
```

Note List elements (in particular, [ol^{p195}](#) and [ul^{p197}](#) elements) cannot be children of [p^{p187}](#) elements. When a sentence contains a bulleted list, therefore, one might wonder how it should be marked up.

Example For instance, this fantastic sentence has bullets relating to

- wizards,
- faster-than-light travel, and
- telepathy,

and is further discussed below.

The solution is to realise that a [paragraph^{p118}](#), in HTML terms, is not a logical concept, but a structural one. In the fantastic example above, there are actually five [paragraphs^{p118}](#) as defined by this specification: one before the list, one for each bullet, and one after the list.

Example The markup for the above example could therefore be:

```
<p>For instance, this fantastic sentence has bullets relating to</p>
<ul>
<li>wizards,
<li>faster-than-light travel, and
<li>telepathy,
</ul>
<p>and is further discussed below.</p>
```

Authors wishing to conveniently style such "logical" paragraphs consisting of multiple "structural" paragraphs can use the [div^{p207}](#) element instead of the [p^{p187}](#) element.

Example Thus for instance the above example could become the following:

```
<div>For instance, this fantastic sentence has bullets relating to
<ul>
<li>wizards,
<li>faster-than-light travel, and
<li>telepathy,
</ul>
and is further discussed below.</div>
```

This example still has five structural paragraphs, but now the author can style just the [div^{p207}](#) instead of having to consider each part of the example separately.

4.4.2 The **hr** element

Categories^{p113}:

[Flow content](#)^{p115}.

Contexts in which this element can be used^{p113}:

Where [flow content](#)^{p115} is expected.

Content model^{p113}:

[Nothing](#)^{p114}.

Tag omission in text/html^{p113}:

No [end tag](#)^{p944}.

Content attributes^{p113}:

[Global attributes](#)^{p120}

DOM interface^{p113}:

IDL

```
interface HTMLHRElement : HTMLElement {
    // also has obsolete members
};
```

The [hr](#)^{p190} element [represents](#)^{p111} a [paragraph](#)^{p118}-level thematic break, e.g. a scene change in a story, or a transition to another topic within a section of a reference book.

Example

The following fictional extract from a project manual shows two sections that use the [hr](#)^{p190} element to separate topics within the section.

```
<section>
    <h1>Communication</h1>
    <p>There are various methods of communication. This section
        covers a few of the important ones used by the project.</p>
    <hr>
    <p>Communication stones seem to come in pairs and have mysterious
        properties:</p>
    <ul>
        <li>They can transfer thoughts in two directions once activated
            if used alone.</li>
        <li>If used with another device, they can transfer one's
            consciousness to another body.</li>
        <li>If both stones are used with another device, the
            consciousnesses switch bodies.</li>
    </ul>
    <hr>
    <p>Radios use the electromagnetic spectrum in the meter range and
        longer.</p>
    <hr>
    <p>Signal flares use the electromagnetic spectrum in the
        nanometer range.</p>
</section>
<section>
    <h1>Food</h1>
    <p>All food at the project is rationed:</p>
    <dl>
        <dt>Potatoes</dt>
        <dd>Two per day</dd>
        <dt>Soup</dt>
        <dd>One bowl per day</dd>
    </dl>
    <hr>
```

```
<p>Cooking is done by the chefs on a set rotation.</p>
</section>
```

There is no need for an [hr^{p190}](#) element between the sections themselves, since the [section^{p161}](#) elements and the [h1^{p168}](#) elements imply thematic changes themselves.

Example

The following extract from *Pandora's Star* by Peter F. Hamilton shows two paragraphs that precede a scene change and the paragraph that follows it. The scene change, represented in the printed book by a gap containing a solitary centered star between the second and third paragraphs, is here represented using the [hr^{p190}](#) element.

```
<p>Dudley was ninety-two, in his second life, and fast approaching  
time for another rejuvenation. Despite his body having the physical  
age of a standard fifty-year-old, the prospect of a long degrading  
campaign within academia was one he regarded with dread. For a  
supposedly advanced civilization, the Intersolar Commonwealth could be  
appallingly backward at times, not to mention cruel.</p>  
<p><i>Maybe it won't be that bad</i>, he told himself. The lie was  
comforting enough to get him through the rest of the night's  
shift.</p>  
<hr>  
<p>The Carlton AllLander drove Dudley home just after dawn. Like the  
astronomer, the vehicle was old and worn, but perfectly capable of  
doing its job. It had a cheap diesel engine, common enough on a  
semi-frontier world like Gralmond, although its drive array was a  
thoroughly modern photoneural processor. With its high suspension and  
deep-tread tyres it could plough along the dirt track to the  
observatory in all weather and seasons, including the metre-deep snow  
of Gralmond's winters.</p>
```

Note [The hr^{p190} element does not affect the document's outline^{p178}](#)

4.4.3 The `pre` element

Spec bugs: [13103](#)

Categories^{p113}:

[Flow content^{p115}](#).

[Palpable content^{p117}](#).

Contexts in which this element can be used^{p113}:

Where [flow content^{p115}](#) is expected.

Content model^{p113}:

[Phrasing content^{p116}](#).

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes^{p120}](#)

DOM interface^{p113}:

```
IDL interface HTMLPreElement : HTMLElement {  
    // also has obsolete members  
};
```

The [pre^{p191}](#) element [represents^{p111}](#) a block of preformatted text, in which structure is represented by typographic conventions rather than by elements.

Note In the HTML syntax^{p941}, a leading newline character immediately following the `pre`^{p191} element start tag is stripped.

Some examples of cases where the `pre`^{p191} element could be used:

- Including an e-mail, with paragraphs indicated by blank lines, lists indicated by lines prefixed with a bullet, and so on.
- Including fragments of computer code, with structure indicated according to the conventions of that language.
- Displaying ASCII art.

Note Authors are encouraged to consider how preformatted text will be experienced when the formatting is lost, as will be the case for users of speech synthesizers, braille displays, and the like. For cases like ASCII art, it is likely that an alternative presentation, such as a textual description, would be more universally accessible to the readers of the document.

To represent a block of computer code, the `pre`^{p191} element can be used with a `code`^{p231} element; to represent a block of computer output the `pre`^{p191} element can be used with a `samp`^{p233} element. Similarly, the `kbd`^{p234} element can be used within a `pre`^{p191} element to indicate text that the user is to enter.

Note This element has rendering requirements involving the bidirectional algorithm^{p132}.

Example

In the following snippet, a sample of computer code is presented.

```
<p>This is the <code>Panel</code> constructor:</p>
<pre><code>function Panel(element, canClose, closeHandler) {
    this.element = element;
    this.canClose = canClose;
    this.closeHandler = function () { if (closeHandler) closeHandler() };
}</code></pre>
```

Example

In the following snippet, `samp`^{p233} and `kbd`^{p234} elements are mixed in the contents of a `pre`^{p191} element to show a session of Zork I.

```
<pre><samp>You are in an open field west of a big white house with a boarded
front door.
There is a small mailbox here.

></samp> <kbd>open mailbox</kbd>

<samp>Opening the mailbox reveals:
A leaflet.

></samp></pre>
```

Example

The following shows a contemporary poem that uses the `pre`^{p191} element to preserve its unusual formatting, which forms an intrinsic part of the poem itself.

```
<pre>
maxling

it is with a          heart
                    heavy

that i admit loss of a feline
so                  loved

a friend lost to the
unknown
(night)

~cdr 11dec07</pre>
```

4.4.4 The `blockquote` element

Categories^{p113}:

[Flow content](#)^{p115}.
[Sectioning root](#)^{p176}.
[Palpable content](#)^{p117}.

Contexts in which this element can be used^{p113}:

Where [flow content](#)^{p115} is expected.

Content model^{p113}:

[Flow content](#)^{p115}.

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes](#)^{p120}

[cite](#)^{p193} — Link to the source of the quotation or more information about the edit

DOM interface^{p113}:

```
IDL interface HTMLQuoteElement : HTMLElement {  
    attribute DOMString cite;  
};
```

Note The [HTMLQuoteElement](#)^{p193} interface is also used by the [q](#)^{p215} element.

The [blockquote](#)^{p193} element [represents](#)^{p111} a section that is quoted from another source.

Content inside a [blockquote](#)^{p193} must be quoted from another source, whose address, if it has one, may be cited in the [cite](#) attribute.

If the [cite](#)^{p193} attribute is present, it must be a [valid URL potentially surrounded by spaces](#)^{p82}. To obtain the corresponding citation link, the value of the attribute must be [resolved](#)^{p82} relative to the element. User agents may allow users to follow such citation links, but they are primarily intended for private use (e.g. by server-side scripts collecting statistics about a site's use of quotations), not for readers.

The content of a [blockquote](#)^{p193} may be abbreviated or may have context added in the conventional manner for the text's language.

Example

For example, in English this is traditionally done using square brackets. Consider a page with the sentence "Fred ate the cracker. He then said he liked apples and fish."; it could be quoted as follows:

```
<blockquote>  
  <p>[Fred] then said he liked [...] fish.</p>  
</blockquote>
```

Attribution for the quotation, if any, must be placed outside the [blockquote](#)^{p193} element.

Example

For example, here the attribution is given in a paragraph after the quote:

```
<blockquote>  
  <p>I contend that we are both atheists. I just believe in one fewer  
  god than you do. When you understand why you dismiss all the other  
  possible gods, you will understand why I dismiss yours.</p>  
</blockquote>  
<p>— Stephen Roberts</p>
```

The other examples below show other ways of showing attribution.

The [cite](#) IDL attribute must [reflect](#)^{p88} the element's [cite](#) content attribute.

Example

Here a `blockquote`^{p193} element is used in conjunction with a `figure`^{p202} element and its `figcaption`^{p205} to clearly relate a quote to its attribution (which is not part of the quote and therefore doesn't belong inside the `blockquote`^{p193} itself):

```
<figure>
  <blockquote>
    <p>The truth may be puzzling. It may take some work to grapple with.  

      It may be counterintuitive. It may contradict deeply held  

      prejudices. It may not be consonant with what we desperately want to  

      be true. But our preferences do not determine what's true. We have a  

      method, and that method helps us to reach not absolute truth, only  

      asymptotic approaches to the truth – never there, just closer  

      and closer, always finding vast new oceans of undiscovered  

      possibilities. Cleverly designed experiments are the key.</p>
  </blockquote>
  <figcaption>Carl Sagan, in "<cite>Wonder and Skepticism</cite>", from  

    the <cite>Skeptical Enquirer</cite> Volume 19, Issue 1 (January–February  

    1995)</figcaption>
</figure>
```

Example

This next example shows the use of `cite`^{p214} alongside `blockquote`^{p193}:

```
<p>His next piece was the aptly named <cite>Sonnet 130</cite>:</p>
<blockquote cite="http://quotes.example.org/s/sonnet130.html">
  <p>My mistress' eyes are nothing like the sun,<br>
  Coral is far more red, than her lips red,<br>
  ...
  ...</p>
</blockquote>
```

Example

This example shows how a forum post could use `blockquote`^{p193} to show what post a user is replying to. The `article`^{p159} element is used for each post, to mark up the threading.

```
<article>
  <h1><a href="http://bacon.example.com/?blog=109431">Bacon on a crowbar</a></h1>
  <article>
    <header><strong>t3yw</strong> 12 points 1 hour ago</header>
    <p>I bet a narwhal would love that.</p>
    <footer><a href="?pid=29578">permalink</a></footer>
  <article>
    <header><strong>greg</strong> 8 points 1 hour ago</header>
    <blockquote><p>I bet a narwhal would love that.</p></blockquote>
    <p>Dude narwhals don't eat bacon.</p>
    <footer><a href="?pid=29579">permalink</a></footer>
  <article>
    <header><strong>t3yw</strong> 15 points 1 hour ago</header>
    <blockquote>
      <blockquote><p>I bet a narwhal would love that.</p></blockquote>
      <p>Dude narwhals don't eat bacon.</p>
    </blockquote>
    <p>Next thing you'll be saying they don't get capes and wizard  

      hats either!</p>

    <footer><a href="?pid=29581">permalink</a></footer>
  </article>
</article>
</article>
<article>
```

```

<header><strong>fred</strong> 1 points 23 minutes ago</header>
<blockquote><p>I bet a narwhal would love that.</p></blockquote>
<p>I bet they'd love to peel a banana too.</p>
<footer><a href="?pid=29582">permalink</a></footer>
</article>
</article>
</article>

```

Example

This example shows the use of a [blockquote^{p193}](#) for short snippets, demonstrating that one does not have to use [p^{p187}](#) elements inside [blockquote^{p193}](#) elements:

```

<p>He began his list of "lessons" with the following:</p>
<blockquote>One should never assume that his side of
the issue will be recognized, let alone that it will
be conceded to have merits.</blockquote>
<p>He continued with a number of similar points, ending with:</p>
<blockquote>Finally, one should be prepared for the threat
of breakdown in negotiations at any given moment and not
be cowed by the possibility.</blockquote>
<p>We shall now discuss these points...

```

Note [Examples of how to represent a conversation^{p674}](#) are shown in a later section; it is not appropriate to use the [cite^{p214}](#) and [blockquote^{p193}](#) elements for this purpose.

Spec bugs: [18263](#)

4.4.5 The `ol` element

Categories^{p113}:

[Flow content^{p115}](#).

If the element's children include at least one [li^{p198}](#) element: [Palpable content^{p117}](#).

Contexts in which this element can be used^{p113}:

Where [flow content^{p115}](#) is expected.

Content model^{p113}:

Zero or more [li^{p198}](#) and [script-supporting^{p117}](#) elements.

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes^{p120}](#)

[reversed^{p196}](#) — Number the list backwards

[start^{p196}](#) — [Ordinal value^{p198}](#) of the first item

[type^{p196}](#) — Kind of list marker

DOM interface^{p113}:

```

IDL
interface HTMLListElement : HTMLElement {
    attribute boolean reversed;
    attribute long start;
    attribute DOMString type;

    // also has obsolete members
};

```

The [ol^{p195}](#) element [represents^{p111}](#) a list of items, where the items have been intentionally ordered, such that changing the order would change the meaning of the document.

The items of the list are the [li^{p198}](#) element child nodes of the [ol^{p195}](#) element, in [tree order^{p42}](#).

The [reversed](#) attribute is a [boolean attribute^{p59}](#). If present, it indicates that the list is a descending list (... , 3, 2, 1). If the attribute is omitted, the list is an ascending list (1, 2, 3, ...).

The [start](#) attribute, if present, must be a [valid integer^{p60}](#) giving the [ordinal value^{p198}](#) of the first list item.

If the [start^{p196}](#) attribute is present, user agents must [parse it as an integer^{p60}](#), in order to determine the attribute's value. The default value, used if the attribute is missing or if the value cannot be converted to a number according to the referenced algorithm, is 1 if the element has no [reversed^{p196}](#) attribute, and is the number of child [li^{p198}](#) elements otherwise.

The first item in the list has the [ordinal value^{p198}](#) given by the [ol^{p195}](#) element's [start^{p196}](#) attribute, unless that [li^{p198}](#) element has a [value^{p198}](#) attribute with a value that can be successfully parsed, in which case it has the [ordinal value^{p198}](#) given by that [value^{p198}](#) attribute.

Each subsequent item in the list has the [ordinal value^{p198}](#) given by its [value^{p198}](#) attribute, if it has one, or, if it doesn't, the [ordinal value^{p198}](#) of the previous item, plus one if the [reversed^{p196}](#) is absent, or minus one if it is present.

The [type](#) attribute can be used to specify the kind of marker to use in the list, in the cases where that matters (e.g. because items are to be referenced by their number/letter). The attribute, if specified, must have a value that is a [case-sensitive^{p58}](#) match for one of the characters given in the first cell of one of the rows of the following table. The [type^{p196}](#) attribute represents the state given in the cell in the second column of the row whose first cell matches the attribute's value; if none of the cells match, or if the attribute is omitted, then the attribute represents the [decimal^{p196}](#) state.

Keyword	State	Description	Examples for values 1-3 and 3999-4001							
1 (U+0031)	decimal	Decimal numbers	1.	2.	3.	...	3999.	4000.	4001.	...
a (U+0061)	lower-alpha	Lowercase latin alphabet	a.	b.	c.	...	ewu.	ewv.	eww.	...
A (U+0041)	upper-alpha	Uppercase latin alphabet	A.	B.	C.	...	EWU.	EWV.	EWW.	...
i (U+0069)	lower-roman	Lowercase roman numerals	i.	ii.	iii.	...	mmmcmlxxix.	īv.	īvi.	...
I (U+0049)	upper-roman	Uppercase roman numerals	I.	II.	III.	...	MMMCMLXXIX.	ĪV.	ĪVI.	...

User agents should render the items of the list in a manner consistent with the state of the [type^{p196}](#) attribute of the [ol^{p195}](#) element. Numbers less than or equal to zero should always use the decimal system regardless of the [type^{p196}](#) attribute.

Note For CSS user agents, a mapping for this attribute to the 'list-style-type' CSS property is given in the rendering section^{p1071} (the mapping is straightforward: the states above have the same names as their corresponding CSS values).

Note It is possible to redefine the default CSS list styles used to implement this attribute in CSS user agents; doing so will affect how list items are rendered.

The [reversed](#), [start](#), and [type](#) IDL attributes must [reflect^{p88}](#) the respective content attributes of the same name. The [start^{p196}](#) IDL attribute has the same default as its content attribute.

Example

The following markup shows a list where the order matters, and where the [ol^{p195}](#) element is therefore appropriate. Compare this list to the equivalent list in the [ul^{p197}](#) section to see an example of the same items using the [ul^{p197}](#) element.

```
<p>I have lived in the following countries (given in the order of when
I first lived there):</p>
<ol>
  <li>Switzerland
  <li>United Kingdom
  <li>United States
  <li>Norway
</ol>
```

Note how changing the order of the list changes the meaning of the document. In the following example, changing the relative order of the first two items has changed the birthplace of the author:

```
<p>I have lived in the following countries (given in the order of when
I first lived there):</p>
<ol>
```

```
<li>United Kingdom  
<li>Switzerland  
<li>United States  
<li>Norway  
</ol>
```

4.4.6 The `ul` element

Categories^{p113}:

[Flow content](#)^{p115}.

If the element's children include at least one [li](#)^{p198} element: [Palpable content](#)^{p117}.

Contexts in which this element can be used^{p113}:

Where [flow content](#)^{p115} is expected.

Content model^{p113}:

Zero or more [li](#)^{p198} and [script-supporting](#)^{p117} elements.

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes](#)^{p120}

DOM interface^{p113}:

```
IDL interface HTMLULListElement : HTMLElement {  
    // also has obsolete members  
};
```

The [ul](#)^{p197} element [represents](#)^{p111} a list of items, where the order of the items is not important — that is, where changing the order would not materially change the meaning of the document.

The items of the list are the [li](#)^{p198} element child nodes of the [ul](#)^{p197} element.

Example

The following markup shows a list where the order does not matter, and where the [ul](#)^{p197} element is therefore appropriate. Compare this list to the equivalent list in the [ol](#)^{p195} section to see an example of the same items using the [ol](#)^{p195} element.

```
<p>I have lived in the following countries:</p>  
<ul>  
    <li>Norway  
    <li>Switzerland  
    <li>United Kingdom  
    <li>United States  
</ul>
```

Note that changing the order of the list does not change the meaning of the document. The items in the snippet above are given in alphabetical order, but in the snippet below they are given in order of the size of their current account balance in 2007, without changing the meaning of the document whatsoever:

```
<p>I have lived in the following countries:</p>  
<ul>  
    <li>Switzerland  
    <li>Norway  
    <li>United Kingdom  
    <li>United States  
</ul>
```

4.4.7 The `li` element

Categories^{p113}:

None.

Contexts in which this element can be used^{p113}:

- Inside `ol`^{p195} elements.
- Inside `ul`^{p197} elements.
- Inside `menu`^{p571} elements whose `type`^{p572} attribute is in the `toolbar`^{p572} state.

Content model^{p113}:

[Flow content](#)^{p115}.

Tag omission in text/html^{p113}:

An `li`^{p198} element's [end tag](#)^{p944} can be omitted if the `li`^{p198} element is immediately followed by another `li`^{p198} element or if there is no more content in the parent element.

Content attributes^{p113}:

[Global attributes](#)^{p120}

If the element is a child of an `ol`^{p195} element: `value`^{p198} — [Ordinal value](#)^{p198} of the list item

DOM interface^{p113}:

```
IDL
interface HTMLLIElement : HTMLElement {
    attribute long value;

    // also has obsolete members
};
```

The `li`^{p198} element [represents](#)^{p111} a list item. If its parent element is an `ol`^{p195}, `ul`^{p197}, or `menu`^{p571} element, then the element is an item of the parent element's list, as defined for those elements. Otherwise, the list item has no defined list-related relationship to any other `li`^{p198} element.

If the parent element is an `ol`^{p195} element, then the `li`^{p198} element has an **ordinal value**.

The `value` attribute, if present, must be a [valid integer](#)^{p60} giving the [ordinal value](#)^{p198} of the list item.

If the `value`^{p198} attribute is present, user agents must [parse it as an integer](#)^{p60}, in order to determine the attribute's value. If the attribute's value cannot be converted to a number, the attribute must be treated as if it was absent. The attribute has no default value.

The `value`^{p198} attribute is processed relative to the element's parent `ol`^{p195} element (q.v.), if there is one. If there is not, the attribute has no effect.

The `value` IDL attribute must [reflect](#)^{p88} the value of the `value`^{p198} content attribute.

Example

The following example, the top ten movies are listed (in reverse order). Note the way the list is given a title by using a `figure`^{p202} element and its `figcaption`^{p205} element.

```
<figure>
  <figcaption>The top 10 movies of all time</figcaption>
  <ol>
    <li value="10"><cite>Josie and the Pussycats</cite>, 2001</li>
    <li value="9"><cite lang="sh">Црна мачка, бели мачор</cite>, 1998</li>
    <li value="8"><cite>A Bug's Life</cite>, 1998</li>
    <li value="7"><cite>Toy Story</cite>, 1995</li>
    <li value="6"><cite>Monsters, Inc</cite>, 2001</li>
    <li value="5"><cite>Cars</cite>, 2006</li>
    <li value="4"><cite>Toy Story 2</cite>, 1999</li>
    <li value="3"><cite>Finding Nemo</cite>, 2003</li>
    <li value="2"><cite>The Incredibles</cite>, 2004</li>
    <li value="1"><cite>Ratatouille</cite>, 2007</li>
  </ol>
</figure>
```

The markup could also be written as follows, using the [reversed^{p196}](#) attribute on the [ol^{p195}](#) element:

```
<figure>
  <figcaption>The top 10 movies of all time</figcaption>
  <ol reversed>
    <li><cite>Josie and the Pussycats</cite>, 2001</li>
    <li><cite lang="sh">Прна мачка, бели мачор</cite>, 1998</li>
    <li><cite>A Bug's Life</cite>, 1998</li>
    <li><cite>Toy Story</cite>, 1995</li>
    <li><cite>Monsters, Inc</cite>, 2001</li>
    <li><cite>Cars</cite>, 2006</li>
    <li><cite>Toy Story 2</cite>, 1999</li>
    <li><cite>Finding Nemo</cite>, 2003</li>
    <li><cite>The Incredibles</cite>, 2004</li>
    <li><cite>Ratatouille</cite>, 2007</li>
  </ol>
</figure>
```

Note While it is conforming to include heading elements (e.g. [h1^{p168}](#)) inside [li^{p198}](#) elements, it likely does not convey the semantics that the author intended. A heading starts a new section, so a heading in a list implicitly splits the list into spanning multiple sections.

4.4.8 The [dl^{p113}](#) element

Categories^{p113}:

[Flow content^{p115}](#).

If the element's children include at least one name-value group: [Palpable content^{p117}](#).

Contexts in which this element can be used^{p113}:

Where [flow content^{p115}](#) is expected.

Content model^{p113}:

Zero or more groups each consisting of one or more [dt^{p201}](#) elements followed by one or more [dd^{p202}](#) elements, optionally intermixed with [script-supporting elements^{p117}](#).

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes^{p120}](#)

DOM interface^{p113}:

```
IDL  interface HTMLListElement : HTMLElement {
  // also has obsolete members
};
```

The [dl^{p199}](#) element [represents^{p111}](#) an association list consisting of zero or more name-value groups (a description list). A name-value group consists of one or more names ([dt^{p201}](#) elements) followed by one or more values ([dd^{p202}](#) elements), ignoring any nodes other than [dt^{p201}](#) and [dd^{p202}](#) elements. Within a single [dl^{p199}](#) element, there should not be more than one [dt^{p201}](#) element for each name.

Name-value groups may be terms and definitions, metadata topics and values, questions and answers, or any other groups of name-value data.

The values within a group are alternatives; multiple paragraphs forming part of the same value must all be given within the same [dd^{p202}](#) element.

The order of the list of groups, and of the names and values within each group, may be significant.

If a [dl^{p199}](#) element has no [dt^{p201}](#) or [dd^{p202}](#) element children, it contains no groups.

If a `dl`^{p199} element has one or more non-`whitespace`^{p113} `Text`^{p51} node children, or has child elements that are neither `dt`^{p201} nor `dd`^{p202} elements, all such `Text`^{p51} nodes and elements, as well as their descendants (including any `dt`^{p201} or `dd`^{p202} elements), do not form part of any groups in that `dl`^{p199}.

If a `dl`^{p199} element has one or more `dt`^{p201} element children but no `dd`^{p202} element children, then it consists of one group with names but no values.

If a `dl`^{p199} element has one or more `dd`^{p202} element children but no `dt`^{p201} element children, then it consists of one group with values but no names.

If a `dl`^{p199} element's first `dt`^{p201} or `dd`^{p202} element child is a `dd`^{p202} element, then the first group has no associated name.

If a `dl`^{p199} element's last `dt`^{p201} or `dd`^{p202} element child is a `dt`^{p201} element, then the last group has no associated value.

Note When a `dl`^{p199} element doesn't match its content model, it is often due to accidentally using `dd`^{p202} elements in the place of `dt`^{p201} elements and vice versa. Conformance checkers can spot such mistakes and might be able to advise authors how to correctly use the markup.

Example

In the following example, one entry ("Authors") is linked to two values ("John" and "Luke").

```
<dl>
  <dt> Authors
  <dd> John
  <dd> Luke
  <dt> Editor
  <dd> Frank
</dl>
```

Example

In the following example, one definition is linked to two terms.

```
<dl>
  <dt lang="en-US"> <dfn>color</dfn> </dt>
  <dt lang="en-GB"> <dfn>colour</dfn> </dt>
  <dd> A sensation which (in humans) derives from the ability of
       the fine structure of the eye to distinguish three differently
       filtered analyses of a view. </dd>
</dl>
```

Example

The following example illustrates the use of the `dl`^{p199} element to mark up metadata of sorts. At the end of the example, one group has two metadata labels ("Authors" and "Editors") and two values ("Robert Rothman" and "Daniel Jackson").

```
<dl>
  <dt> Last modified time </dt>
  <dd> 2004-12-23T23:33Z </dd>
  <dt> Recommended update interval </dt>
  <dd> 60s </dd>
  <dt> Authors </dt>
  <dt> Editors </dt>
  <dd> Robert Rothman </dd>
  <dd> Daniel Jackson </dd>
</dl>
```

Example

The following example shows the `dl`^{p199} element used to give a set of instructions. The order of the instructions here is important (in the other examples, the order of the blocks was not important).

```
<p>Determine the victory points as follows (use the
first matching case):</p>
<dl>
  <dt> If you have exactly five gold coins </dt>
  <dd> You get five victory points </dd>
  <dt> If you have one or more gold coins, and you have one or more silver coins </dt>
```

```

<dd> You get two victory points </dd>
<dt> If you have one or more silver coins </dt>
<dd> You get one victory point </dd>
<dt> Otherwise </dt>
<dd> You get no victory points </dd>
</dl>

```

Example

The following snippet shows a [dl^{p199}](#) element being used as a glossary. Note the use of [dfn^{p217}](#) to indicate the word being defined.

```

<dl>
<dt><dfn>Apartment</dfn>, n.</dt>
<dd>An execution context grouping one or more threads with one or
more COM objects.</dd>
<dt><dfn>Flat</dfn>, n.</dt>
<dd>A deflated tire.</dd>
<dt><dfn>Home</dfn>, n.</dt>
<dd>The user's login directory.</dd>
</dl>

```

Note The [dl^{p199}](#) element is inappropriate for marking up dialogue. [Examples of how to mark up dialogue^{p674}](#) are shown below.

4.4.9 The **dt** element

Categories^{p113}:

None.

Contexts in which this element can be used^{p113}:

Before [dd^{p202}](#) or [dt^{p201}](#) elements inside [dl^{p199}](#) elements.

Content model^{p113}:

[Flow content^{p115}](#), but with no [header^{b171}](#), [footer^{p173}](#), [sectioning content^{p116}](#), or [heading content^{b116}](#) descendants.

Tag omission in text/html^{p113}:

A [dt^{p201}](#) element's [end tag^{p944}](#) can be omitted if the [dt^{p201}](#) element is immediately followed by another [dt^{p201}](#) element or a [dd^{p202}](#) element.

Content attributes^{p113}:

[Global attributes^{p120}](#)

DOM interface^{p113}:

Uses [HTMLElement^{p112}](#).

The [dt^{p201}](#) element [represents^{p111}](#) the term, or name, part of a term-description group in a description list ([dl^{p199}](#) element).

Note The [dt^{p201}](#) element itself, when used in a [dl^{p199}](#) element, does not indicate that its contents are a term being defined, but this can be indicated using the [dfn^{p217}](#) element.

Example

This example shows a list of frequently asked questions (a FAQ) marked up using the [dt^{p201}](#) element for questions and the [dd^{p202}](#) element for answers.

```

<article>
<h1>FAQ</h1>
<dl>
<dt>What do we want?</dt>
<dd>Our data.</dd>
<dt>When do we want it?</dt>
<dd>Now.</dd>
<dt>Where is it?</dt>
<dd>We are not sure.</dd>
</dl>

```

```
</dl>
</article>
```

4.4.10 The `dd` element

Categories^{p113}:

None.

Contexts in which this element can be used^{p113}:

After `dt`^{p201} or `dd`^{p202} elements inside `dl`^{p199} elements.

Content model^{p113}:

[Flow content](#)^{p115}.

Tag omission in text/html^{p113}:

A `dd`^{p202} element's [end tag](#)^{p944} can be omitted if the `dd`^{p202} element is immediately followed by another `dd`^{p202} element or a `dt`^{p201} element, or if there is no more content in the parent element.

Content attributes^{p113}:

[Global attributes](#)^{p120}

DOM interface^{p113}:

Uses [HTMLElement](#)^{p112}.

The `dd`^{p202} element [represents](#)^{p111} the description, definition, or value, part of a term-description group in a description list (`dl`^{p199} element).

Example

A `dl`^{p199} can be used to define a vocabulary list, like in a dictionary. In the following example, each entry, given by a `dt`^{p201} with a `dfn`^{p217}, has several `dd`^{p202}s, showing the various parts of the definition.

```
<dl>
  <dt><dfn>happiness</dfn></dt>
  <dd class="pronunciation">/'hæ p. nes/</dd>
  <dd class="part-of-speech"><i>n.</i><abbr>n.</abbr></i></dd>
  <dd>The state of being happy.</dd>
  <dd>Good fortune; success. <q>Oh <b>happiness</b>! It worked!</q></dd>
  <dt><dfn>rejoice</dfn></dt>
  <dd class="pronunciation">/ri jois'/</dd>
  <dd><i>v.intr.</i> To be delighted oneself.</dd>
  <dd><i>v.tr.</i> To cause one to be delighted.</dd>
</dl>
```

4.4.11 The `figure` element

Spec bugs: [25552](#)

Categories^{p113}:

[Flow content](#)^{p115}.

[Sectioning root](#)^{p176}.

[Palpable content](#)^{p117}.

Contexts in which this element can be used^{p113}:

Where [flow content](#)^{p115} is expected.

Content model^{p113}:

Either: One [figcaption](#)^{p205} element followed by [flow content](#)^{p115}.

Or: [Flow content](#)^{p115} followed by one [figcaption](#)^{p205} element.

Or: [Flow content](#)^{p115}.

Tag omission in text/html^{p113}:

Neither tag is ommissible.

Content attributes^{p113}:

[Global attributes](#)^{p120}

DOM interface^{p113}:

Uses [HTMLElement](#)^{p112}.

The [figure](#)^{p202} element [represents](#)^{p111} some [flow content](#)^{p115}, optionally with a caption, that is self-contained (like a complete sentence) and is typically referenced as a single unit from the main flow of the document.

Note *Self-contained in this context does not necessarily mean independent. For example, each sentence in a paragraph is self-contained; an image that is part of a sentence would be inappropriate for [figure](#)^{p202}, but an entire sentence made of images would be fitting.*

The element can thus be used to annotate illustrations, diagrams, photos, code listings, etc.

Note *When a [figure](#)^{p202} is referred to from the main content of the document by identifying it by its caption (e.g. by figure number), it enables such content to be easily moved away from that primary content, e.g. to the side of the page, to dedicated pages, or to an appendix, without affecting the flow of the document.*

If a [figure](#)^{p202} element is referenced by its relative position, e.g. "in the photograph above" or "as the next figure shows", then moving the figure would disrupt the page's meaning. Authors are encouraged to consider using labels to refer to figures, rather than using such relative references, so that the page can easily be restyled without affecting the page's meaning.

The first [figcaption](#)^{p205} element child of the element, if any, represents the caption of the [figure](#)^{p202} element's contents. If there is no child [figcaption](#)^{p205} element, then there is no caption.

A [figure](#)^{p202} element's contents are part of the surrounding flow. If the purpose of the page is to display the figure, for example a photograph on an image sharing site, the [figure](#)^{p202} and [figcaption](#)^{p205} elements can be used to explicitly provide a caption for that figure. For content that is only tangentially related, or that serves a separate purpose than the surrounding flow, the [aside](#)^{p166} element should be used (and can itself wrap a [figure](#)^{p202}). For example, a pull quote that repeats content from an [article](#)^{p159} would be more appropriate in an [aside](#)^{p166} than in a [figure](#)^{p202}, because it isn't part of the content, it's a repetition of the content for the purposes of enticing readers or highlighting key topics.

Example

This example shows the [figure](#)^{p202} element to mark up a code listing.

```
<p>In <a href="#l4">listing 4</a> we see the primary core interface
API declaration.</p>
<figure id="l4">
  <figcaption>Listing 4. The primary core interface API declaration.</figcaption>
  <pre><code>interface PrimaryCore {
    boolean verifyDataLine();
    void sendData(in sequence<byte> data);
    void initSelfDestruct();
}</code></pre>
</figure>
<p>The API is designed to use UTF-8.</p>
```

Example

Here we see a [figure](#)^{p202} element to mark up a photo that is the main content of the page (as in a gallery).

```
<!DOCTYPE HTML>
<title>Bubbles at work – My Gallery™</title>
<figure>
  
  <figcaption>Bubbles at work</figcaption>
</figure>
<nav><a href="19414.html">Prev</a> – <a href="19416.html">Next</a></nav>
```

Example

In this example, we see an image that is *not* a figure, as well as an image and a video that are. The first image is literally part of the example's second sentence, so it's not a self-contained unit, and thus figure^{p202} would be inappropriate.

```
<h2>Malinko's comics</h2>

<p>This case centered on some sort of "intellectual property" infringement related to a comic (see Exhibit A). The suit started after a trailer ending with these words:

<blockquote>
  
</blockquote>

<p>...was aired. A lawyer, armed with a Bigger Notebook, launched a preemptive strike using snowballs. A complete copy of the trailer is included with Exhibit B.

<figure>
  
  <figcaption>Exhibit A. The alleged <cite>rough copy</cite> comic.</figcaption>
</figure>

<figure>
  <video src="ex-b.mov"></video>
  <figcaption>Exhibit B. The <cite>Rough Copy</cite> trailer.</figcaption>
</figure>

<p>The case was resolved out of court.
```

Example

Here, a part of a poem is marked up using figure^{p202}.

```
<figure>
  <p>'Twas brillig, and the slithy toves<br>
  Did gyre and gimble in the wabe;<br>
  All mimsy were the borogoves,<br>
  And the mome raths outgrabe.</p>
  <figcaption><cite>Jabberwocky</cite> (first verse). Lewis Carroll, 1832-98</figcaption>
</figure>
```

Example

In this example, which could be part of a much larger work discussing a castle, nested figure^{p202} elements are used to provide both a group caption and individual captions for each figure in the group:

```
<figure>
  <figcaption>The castle through the ages: 1423, 1858, and 1999 respectively.</figcaption>
  <figure>
    <figcaption>Etching. Anonymous, ca. 1423.</figcaption>
    
  </figure>
  <figure>
    <figcaption>Oil-based paint on canvas. Maria Towle, 1858.</figcaption>
    
  </figure>
  <figure>
    <figcaption>Film photograph. Peter Jankle, 1999.</figcaption>
    
  </figure>
</figure>
```

Example

The previous example could also be more succinctly written as follows (using [title^{p122}](#) attributes in place of the nested [figure^{p202}](#)/[figcaption^{p205}](#) pairs):

```
<figure>
  
  
  
  <figcaption>The castle through the ages: 1423, 1858, and 1999 respectively.</figcaption>
</figure>
```

Example

The figure is sometimes referenced only implicitly from the content:

```
<article>
  <h1>Fiscal negotiations stumble in Congress as deadline nears</h1>
  <figure>
    
    <figcaption>Barak Obama and Harry Reid. White House press photograph.</figcaption>
  </figure>
  <p>Negotiations in Congress to end the fiscal impasse sputtered on Tuesday, leaving both
  chambers
  grasping for a way to reopen the government and raise the country's borrowing authority with a
  Thursday deadline drawing near.</p>
  ...
</article>
```

4.4.12 The [figcaption](#) element

Spec bugs: [12835](#)

Categories^{p113}:

None.

Contexts in which this element can be used^{p113}:

As the first or last child of a [figure^{p202}](#) element.

Content model^{p113}:

[Flow content^{p115}](#).

Tag omission in text/html^{p113}:

Neither tag is omissionable.

Content attributes^{p113}:

[Global attributes^{p120}](#)

DOM interface^{p113}:

Uses [HTMLElement^{p112}](#).

The [figcaption^{p205}](#) element [represents^{p111}](#) a caption or legend for the rest of the contents of the [figcaption^{p205}](#) element's parent [figure^{p202}](#) element, if any.

4.4.13 The [main](#) element

Categories^{p113}:

[Flow content^{p115}](#).

[Palpable content^{p117}](#).

Contexts in which this element can be used^{p113}:

Where [flow content^{p115}](#) is expected.

Content model^{p113}:

[Flow content^{p115}](#).

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes^{p120}](#)

DOM interface^{p113}:

Uses [HTMLElement^{p112}](#).

The [main^{p205}](#) element can be used as a container for the dominant contents of another element. It [represents^{p111}](#) its children.

Note *The [main^{p205}](#) element is distinct from the [section^{p161}](#) and [article^{p159}](#) elements in that the [main^{p205}](#) element does not contribute to the document outline^{p178}.*

Note *There is no restriction as to the number of [main^{p205}](#) elements in a document. Indeed, there are many cases where it would make sense to have multiple [main^{p205}](#) elements. For example, a page with multiple [article^{p159}](#) elements might need to indicate the dominant contents of each such element.*

Example

In this example, the author has used a presentation where each component of the page is rendered in a box. To wrap the main content of the page (as opposed to the header, the footer, the navigation bar, and a sidebar), the [main^{p205}](#) element is used.

```
<!DOCTYPE html>
<title>RPG System 17</title>
<style>
  header, nav, aside, main, footer {
    margin: 0.5em; border: thin solid; padding: 0.5em;
    background: #EFF; color: black; box-shadow: 0 0 0.25em #033;
  }
  h1, h2, p { margin: 0; }
  nav, main { float: left; }
  aside { float: right; }
  footer { clear: both; }
</style>
<header>
  <h1>System Eighteen</h1>
</header>
<nav>
  <a href="#">..16/">← System 17</a>
  <a href="#">..18/">RPXIX →</a>
</nav>
<aside>
  <p>This system has no HP mechanic, so there's no healing.</p>
</aside>
<main>
  <h2>Character creation</h2>
  <p>Attributes \\(magic, strength, agility\\) are purchased at the cost of one point per level.</p>
  <h2>Rolls</h2>
  <p>Each encounter, roll the dice for all your skills. If you roll more than the opponent, you win.</p>
</main>
<footer>
  <p>Copyright © 2013</p>
</footer>
```

4.4.14 The `div` element

Categories^{p113}:

[Flow content](#)^{p115}.
[Palpable content](#)^{p117}.

Contexts in which this element can be used^{p113}:

Where [flow content](#)^{p115} is expected.

Content model^{p113}:

[Flow content](#)^{p115}.

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes](#)^{p120}

DOM interface^{p113}:

IDL

```
interface HTMLDivElement : HTMLElement {  
    // also has obsolete members  
};
```

The `div`^{p207} element has no special meaning at all. It [represents](#)^{p111} its children. It can be used with the `class`^{p128}, `lang`^{p123}, and `title`^{p122} attributes to mark up semantics common to a group of consecutive elements.

Note Authors are strongly encouraged to view the `div`^{p207} element as an element of last resort, for when no other element is suitable. Use of more appropriate elements instead of the `div`^{p207} element leads to better accessibility for readers and easier maintainability for authors.

Example

For example, a blog post would be marked up using `article`^{p159}, a chapter using `section`^{p161}, a page's navigation aids using `nav`^{p163}, and a group of form controls using `fieldset`^{p524}.

On the other hand, `div`^{p207} elements can be useful for stylistic purposes or to wrap multiple paragraphs within a section that are all to be annotated in a similar way. In the following example, we see `div`^{p207} elements used as a way to set the language of two paragraphs at once, instead of setting the language on the two paragraph elements separately:

```
<article lang="en-US">  
    <h1>My use of language and my cats</h1>  
    <p>My cat's behaviour hasn't changed much since her absence, except  
        that she plays her new physique to the neighbors regularly, in an  
        attempt to get pets.</p>  
    <div lang="en-GB">  
        <p>My other cat, coloured black and white, is a sweetie. He followed  
            us to the pool today, walking down the pavement with us. Yesterday  
            he apparently visited our neighbours. I wonder if he recognises that  
            their flat is a mirror image of ours.</p>  
        <p>Hm, I just noticed that in the last paragraph I used British  
            English. But I'm supposed to write in American English. So I  
            shouldn't say "pavement" or "flat" or "colour"...</p>  
    </div>  
    <p>I should say "sidewalk" and "apartment" and "color"!</p>  
</article>
```

4.5 Text-level semantics

4.5.1 The `a` element

Categories^{p113}:

[Flow content](#)^{p115}.
[Phrasing content](#)^{p116}.
[Interactive content](#)^{p116}.
[Palpable content](#)^{p117}.

Contexts in which this element can be used^{p113}:

Where [phrasing content](#)^{p116} is expected.

Content model^{p113}:

[Transparent](#)^{p117}, but there must be no [interactive content](#)^{p116} descendant.

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes](#)^{p120}
[href](#)^{p245} — Address of the [hyperlink](#)^{p245}
[target](#)^{p245} — [Browsing context](#)^{p762} for [hyperlink](#)^{p245} [navigation](#)^{p791}
[download](#)^{p246} — Whether to download the resource instead of navigating to it, and its file name if so
[ping](#)^{p246} — [URLs](#)^{p48} to ping
[rel](#)^{p246} — Relationship between the document containing the hyperlink and the destination resource
[hreflang](#)^{p246} — Language of the linked resource
[type](#)^{p246} — Hint for the type of the referenced resource

DOM interface^{p113}:

```
IDL interface HTMLAnchorElement : HTMLElement {
    attribute DOMString target;
    attribute DOMString download;
    [PutForwards=value] attribute DOMSettableTokenList ping;
    attribute DOMString rel;
    readonly attribute DOMTokenList relList;
    attribute DOMString hreflang;
    attribute DOMString type;

    attribute DOMString text;

    // also has obsolete members
};

HTMLAnchorElement implements URLUtils;
```

If the [a](#)^{p208} element has an [href](#)^{p245} attribute, then it [represents](#)^{p111} a [hyperlink](#)^{p245} (a hypertext anchor) labeled by its contents.

If the [a](#)^{p208} element has no [href](#)^{p245} attribute, then the element [represents](#)^{p111} a placeholder for where a link might otherwise have been placed, if it had been relevant, consisting of just the element's contents.

The [target](#)^{p245}, [download](#)^{p246}, [ping](#)^{p246}, [rel](#)^{p246}, [hreflang](#)^{p246}, and [type](#)^{p246} attributes must be omitted if the [href](#)^{p245} attribute is not present.

If the [itemprop](#)^{p692} attribute is specified on an [a](#)^{p208} element, then the [href](#)^{p245} attribute must also be specified.

Example

If a site uses a consistent navigation toolbar on every page, then the link that would normally link to the page itself could be marked up using an [a](#)^{p208} element:

```
<nav>
  <ul>
```

```

<li> <a href="/">Home</a> </li>
<li> <a href="/news">News</a> </li>
<li> <a>Examples</a> </li>
<li> <a href="/legal">Legal</a> </li>
</ul>
</nav>

```

The [href](#), [target](#), [download](#), and [ping](#) attributes affect what happens when users [follow hyperlinks](#) or [download hyperlinks](#) created using the [a](#) element. The [rel](#), [hreflang](#), and [type](#) attributes may be used to indicate to the user the likely nature of the target resource before the user follows the link.

The [activation behaviour](#) of [a](#) elements that create [hyperlinks](#) is to run the following steps:

1. If the [a](#) element's [node document](#) is not [fully active](#), then abort these steps.
2. If either the [a](#) element has a [download](#) attribute and the algorithm is not [allowed to show a popup](#); or, if the user has not indicated a specific [browsing context](#) for following the link, and the element's [target](#) attribute is present, and applying [the rules for choosing a browsing context given a browsing context name](#), using the value of the [target](#) attribute as the browsing context name, would result in there not being a chosen browsing context, then run these substeps:
 1. If there is an [entry settings object](#), throw an [InvalidAccessError](#) exception.
 2. Abort these steps without following the hyperlink.
3. If the target of the [click](#) event is an [img](#) element with an [ismap](#) attribute specified, then server-side image map processing must be performed, as follows:
 1. If the [click](#) event was a real pointing-device-triggered [click](#) event on the [img](#) element, then let x be the distance in CSS pixels from the left edge of the image's left border, if it has one, or the left edge of the image otherwise, to the location of the click, and let y be the distance in CSS pixels from the top edge of the image's top border, if it has one, or the top edge of the image otherwise, to the location of the click. Otherwise, let x and y be zero.
 2. Let the **hyperlink suffix** be a U+003F QUESTION MARK character, the value of x expressed as a base-ten integer using [ASCII digits](#), a U+002C COMMA character (,), and the value of y expressed as a base-ten integer using [ASCII digits](#).
4. Finally, the user agent must [follow the hyperlink](#) or [download the hyperlink](#) created by the [a](#) element, as determined by the [download](#) attribute and any expressed user preference. If the steps above defined a [hyperlink suffix](#), then take that into account when following or downloading the hyperlink.

Note

[a . text](#)
Same as [textContent](#).

The IDL attributes [download](#), [ping](#), [target](#), [rel](#), [hreflang](#), and [type](#), must [reflect](#) the respective content attributes of the same name.

The IDL attribute [relList](#) must [reflect](#) the [rel](#) content attribute.

The [text](#) IDL attribute, on getting, must return the same value as the [textContent](#) IDL attribute on the element, and on setting the [textContent](#) IDL attribute on the element had been set to the new value.

The [a](#) element also supports the [URLUtils](#) interface. [\[URL\]](#)

When the element is created, and whenever the element's [href](#) content attribute is set, changed, or removed, the user agent's [URLUtils](#) interface's [set the input](#) algorithm with the value of the [href](#) content attribute, if any, or the null value.

The element's [URLUtils](#) interface's [get the base](#) algorithm must simply return [the element's base URL](#).

The element's [URLUtils](#) interface's [query encoding](#) is the [document's character encoding](#).

Support:	
Chrome	None
IE	None
Chrome for Android	None
Firefox	30+
iOS Safari	None
Android Browser	None
UC Browser for Android	None
Opera Mini	None
Safari	None
Opera	None
IE Mobile	None
Firefox for Android	33+

Source: [caniuse.com](#)

When the element's [URLUtils](#)^{p48} interface invokes its [update steps](#)^{p48} with a string *value*, the user agent must set the element's [href](#)^{p245} content attribute to the string *value*.

Example

The [a](#)^{b208} element may be wrapped around entire paragraphs, lists, tables, and so forth, even entire sections, so long as there is no interactive content within (e.g. buttons or other links). This example shows how this can be used to make an entire advertising block into a link:

```
<aside class="advertising">
  <h1>Advertising</h1>
  <a href="http://ad.example.com/?adid=1929&pubid=1422">
    <section>
      <h1>Mellblomatic 9000!</h1>
      <p>Turn all your widgets into mellbloms!</p>
      <p>Only $9.99 plus shipping and handling.</p>
    </section>
  </a>
  <a href="http://ad.example.com/?adid=375&pubid=1422">
    <section>
      <h1>The Mellblom Browser</h1>
      <p>Web browsing at the speed of light.</p>
      <p>No other browser goes faster!</p>
    </section>
  </a>
</aside>
```

4.5.2 The **em** element

Categories^{p113}:

[Flow content](#)^{p115}.
[Phrasing content](#)^{p116}.
[Palpable content](#)^{p117}.

Contexts in which this element can be used^{p113}:

Where [phrasing content](#)^{p116} is expected.

Content model^{p113}:

[Phrasing content](#)^{p116}.

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes](#)^{p120}

DOM interface^{p113}:

Uses [HTMLElement](#)^{p112}.

The [em](#)^{p210} element [represents](#)^{p111} stress emphasis of its contents.

The level of stress that a particular piece of content has is given by its number of ancestor [em](#)^{p210} elements.

The placement of stress emphasis changes the meaning of the sentence. The element thus forms an integral part of the content. The precise way in which stress is used in this way depends on the language.

Example

These examples show how changing the stress emphasis changes the meaning. First, a general statement of fact, with no stress:

```
<p>Cats are cute animals.</p>
```

By emphasizing the first word, the statement implies that the kind of animal under discussion is in question (maybe someone is asserting that dogs are cute):

```
<p><em>Cats</em> are cute animals.</p>
```

Moving the stress to the verb, one highlights that the truth of the entire sentence is in question (maybe someone is saying cats are not cute):

```
<p>Cats <em>are</em> cute animals.</p>
```

By moving it to the adjective, the exact nature of the cats is reasserted (maybe someone suggested cats were *mean* animals):

```
<p>Cats are <em>cute</em> animals.</p>
```

Similarly, if someone asserted that cats were vegetables, someone correcting this might emphasise the last word:

```
<p>Cats are cute <em>animals</em>.</p>
```

By emphasizing the entire sentence, it becomes clear that the speaker is fighting hard to get the point across. This kind of stress emphasis also typically affects the punctuation, hence the exclamation mark here.

```
<p><em>Cats are cute animals!</em></p>
```

Anger mixed with emphasizing the cuteness could lead to markup such as:

```
<p><em>Cats are <em>cute</em> animals!</em></p>
```

Note The [em^{p210}](#) element isn't a generic "italics" element. Sometimes, text is intended to stand out from the rest of the paragraph, as if it was in a different mood or voice. For this, the [i^{p235}](#) element is more appropriate.

The [em^{p210}](#) element also isn't intended to convey importance; for that purpose, the [strong^{p211}](#) element is more appropriate.

4.5.3 The **strong** element

Categories^{p113}:

[Flow content^{p115}](#).
[Phrasing content^{p116}](#).
[Palpable content^{p117}](#).

Contexts in which this element can be used^{p113}:

Where [phrasing content^{p116}](#) is expected.

Content model^{p113}:

[Phrasing content^{p116}](#).

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes^{p120}](#).

DOM interface^{p113}:

Uses [HTMLElement^{p112}](#).

The [strong^{p211}](#) element [represents^{p111}](#) strong importance, seriousness, or urgency for its contents.

Importance: The [strong^{p211}](#) element can be used in a heading, caption, or paragraph to distinguish the part that really matters from other parts that might be more detailed, more jovial, or merely boilerplate. (This is distinct from marking up subheadings, for which the [hgroup^{p170}](#) element is appropriate.)

Example For example, the first word of the previous paragraph is marked up with [strong^{p211}](#) to distinguish it from the more detailed text in the rest of the paragraph.

Seriousness: The strong^{p211} element can be used to mark up a warning or caution notice.

Urgency: The strong^{p211} element can be used to denote contents that the user needs to see sooner than other parts of the document.

The relative level of importance of a piece of content is given by its number of ancestor strong^{p211} elements; each strong^{p211} element increases the importance of its contents.

Changing the importance of a piece of text with the strong^{p211} element does not change the meaning of the sentence.

Example

Here, the word "chapter" and the actual chapter number are mere boilerplate, and the actual name of the chapter is marked up with strong^{p211}:

```
<h1>Chapter 1: <strong>The Praxis</strong></h1>
```

In the following example, the name of the diagram in the caption is marked up with strong^{p211}, to distinguish it from boilerplate text (before) and the description (after):

```
<figcaption>Figure 1. <strong>Ant colony dynamics</strong>. The ants in this colony are affected by the heat source (upper left) and the food source (lower right).</figcaption>
```

In this example, the heading is really "Flowers, Bees, and Honey", but the author has added a light-hearted addition to the heading. The strong^{p211} element is thus used to mark up the first part to distinguish it from the latter part.

```
<h1><strong>Flowers, Bees, and Honey</strong> and other things I don't understand</h1>
```

Example

Here is an example of a warning notice in a game, with the various parts marked up according to how important they are:

```
<p><strong>Warning.</strong> This dungeon is dangerous.  
<strong>Avoid the ducks.</strong> Take any gold you find.  
<strong><strong>Do not take any of the diamonds</strong>,  
they are explosive and <strong>will destroy anything within  
ten meters.</strong></strong> You have been warned.</p>
```

Example

In this example, the strong^{p211} element is used to denote the part of the text that the user is intended to read first.

```
<p>Welcome to Remy, the reminder system.</p>  
<p>Your tasks for today:</p>  
<ul>  
  <li><p><strong>Turn off the oven.</strong></p></li>  
  <li><p>Put out the trash.</p></li>  
  <li><p>Do the laundry.</p></li>  
</ul>
```

4.5.4 The small element

Categories^{p113}:

[Flow content](#)^{p115}.
[Phrasing content](#)^{p116}.
[Palpable content](#)^{p117}.

Contexts in which this element can be used^{p113}:

Where [phrasing content](#)^{p116} is expected.

Content model^{p113}:

[Phrasing content](#)^{p116}.

Tag omission in text/html^{p113}:

Neither tag is ommissible.

Content attributes^{p113}:

[Global attributes](#)^{p120}

DOM interface^{p113}:

Uses [HTMLElement](#)^{p112}.

The [small](#)^{p212} element [represents](#)^{p111} side comments such as small print.

Note Small print typically features disclaimers, caveats, legal restrictions, or copyrights. Small print is also sometimes used for attribution, or for satisfying licensing requirements.

Note The [small](#)^{p212} element does not "de-emphasize" or lower the importance of text emphasized by the [em](#)^{p210} element or marked as important with the [strong](#)^{p211} element. To mark text as not emphasized or important, simply do not mark it up with the [em](#)^{p210} or [strong](#)^{p211} elements respectively.

The [small](#)^{p212} element should not be used for extended spans of text, such as multiple paragraphs, lists, or sections of text. It is only intended for short runs of text. The text of a page listing terms of use, for instance, would not be a suitable candidate for the [small](#)^{p212} element: in such a case, the text is not a side comment, it is the main content of the page.

The [small](#)^{p212} element must not be used for subheadings; for that purpose, use the [hgroup](#)^{p170} element.

Example

In this example, the [small](#)^{p212} element is used to indicate that value-added tax is not included in a price of a hotel room:

Example

```
<dl>
  <dt>Single room
  <dd>199 € <small>breakfast included, VAT not included</small>
  <dt>Double room
  <dd>239 € <small>breakfast included, VAT not included</small>
</dl>
```

Example

In this second example, the [small](#)^{p212} element is used for a side comment in an article.

```
<p>Example Corp today announced record profits for the
second quarter <small>(Full Disclosure: Foo News is a subsidiary of
Example Corp)</small>, leading to speculation about a third quarter
merger with Demo Group.</p>
```

This is distinct from a sidebar, which might be multiple paragraphs long and is removed from the main flow of text. In the following example, we see a sidebar from the same article. This sidebar also has small print, indicating the source of the information in the sidebar.

```
<aside>
  <h1>Example Corp</h1>
  <p>This company mostly creates small software and Web
sites.</p>
  <p>The Example Corp company mission is "To provide entertainment
and news on a sample basis".</p>
  <p><small>Information obtained from <a
href="http://example.com/about.html">example.com</a> home
page.</small></p>
</aside>
```

Example

In this last example, the [small](#)^{p212} element is marked as being *important* small print.

```
<p><strong><small>Continued use of this service will result in a kiss.</small></strong></p>
```

4.5.5 The **s** element

Categories^{p113}:

[Flow content](#)^{p115}.
[Phrasing content](#)^{p116}.
[Palpable content](#)^{p117}.

Contexts in which this element can be used^{p113}:

Where [phrasing content](#)^{p116} is expected.

Content model^{p113}:

[Phrasing content](#)^{p116}.

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes](#)^{p120}

DOM interface^{p113}:

Uses [HTMLElement](#)^{p112}.

The **s**^{p214} element [represents](#)^{p111} contents that are no longer accurate or no longer relevant.

Note *The **s**^{p214} element is not appropriate when indicating document edits; to mark a span of text as having been removed from a document, use the **del**^{p262} element.*

Example

In this example a recommended retail price has been marked as no longer relevant as the product in question has a new sale price.

```
<p>Buy our Iced Tea and Lemonade!</p>
<p><s>Recommended retail price: $3.99 per bottle</s></p>
<p><strong>Now selling for just $2.99 a bottle!</strong></p>
```

4.5.6 The **cite** element

Categories^{p113}:

[Flow content](#)^{p115}.
[Phrasing content](#)^{p116}.
[Palpable content](#)^{p117}.

Contexts in which this element can be used^{p113}:

Where [phrasing content](#)^{p116} is expected.

Content model^{p113}:

[Phrasing content](#)^{p116}.

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes](#)^{p120}

DOM interface^{p113}:

Uses [HTMLElement](#)^{p112}.

The **cite**^{p214} element [represents](#)^{p111} the title of a work (e.g. a book, a paper, an essay, a poem, a score, a song, a script, a film, a TV show, a game, a sculpture, a painting, a theatre production, a play, an opera, a musical, an exhibition, a legal case report, a computer program, etc). This can be a work that is being quoted or referenced in detail (i.e. a citation), or it can just be a work that is mentioned in passing.

A person's name is not the title of a work — even if people call that person a piece of work — and the element must therefore not be used to mark up people's names. (In some cases, the **b**^{p236} element might be appropriate for names; e.g. in a gossip article where the names of famous people

are keywords rendered with a different style to draw attention to them. In other cases, if an element is *really* needed, the [span^{p242}](#) element can be used.)

Example

This next example shows a typical use of the [cite^{p214}](#) element:

```
<p>My favorite book is <cite>The Reality Dysfunction</cite> by Peter F. Hamilton. My favorite comic is <cite>Pearls Before Swine</cite> by Stephan Pastis. My favorite track is <cite>Jive Samba</cite> by the Cannonball Adderley Sextet.</p>
```

Example

This is correct usage:

```
<p>According to the Wikipedia article <cite>HTML</cite>, as it stood in mid-February 2008, leaving attribute values unquoted is unsafe. This is obviously an over-simplification.</p>
```

The following, however, is incorrect usage, as the [cite^{p214}](#) element here is containing far more than the title of the work:

```
<!-- do not copy this example, it is an example of bad usage! -->
<p>According to <cite>the Wikipedia article on HTML</cite>, as it stood in mid-February 2008, leaving attribute values unquoted is unsafe. This is obviously an over-simplification.</p>
```

Example

The [cite^{p214}](#) element is obviously a key part of any citation in a bibliography, but it is only used to mark the title:

```
<p><cite>Universal Declaration of Human Rights</cite>, United Nations, December 1948. Adopted by General Assembly resolution 217 A (III).</p>
```

Note A citation is not a quote (for which the [q^{p215}](#) element is appropriate).

Example

This is incorrect usage, because [cite^{p214}](#) is not for quotes:

```
<p><cite>This is wrong!</cite>, said Ian.</p>
```

This is also incorrect usage, because a person is not a work:

```
<p><q>This is still wrong!</q>, said <cite>Ian</cite>.</p>
```

The correct usage does not use a [cite^{p214}](#) element:

```
<p><q>This is correct</q>, said Ian.</p>
```

As mentioned above, the [b^{p236}](#) element might be relevant for marking names as being keywords in certain kinds of documents:

```
<p>And then <b>Ian</b> said <q>this might be right, in a gossip column, maybe!</q>.</p>
```

4.5.7 The [q](#) element

Categories^{p113}:

[Flow content^{p115}](#).

[Phrasing content^{p116}](#).

[Palpable content^{p117}](#).

Contexts in which this element can be used^{p113}:

Where [phrasing content^{p116}](#) is expected.

Content model^{p113}:

[Phrasing content^{p116}.](#)

Tag omission in text/html^{p113}:

Neither tag is omissionable.

Content attributes^{p113}:

[Global attributes^{p120}](#)

[cite^{p216}](#) — Link to the source of the quotation or more information about the edit

DOM interface^{p113}:

Uses [HTMLQuoteElement^{p193}](#).

The [q^{p215}](#) element [represents^{p111}](#) some [phrasing content^{p116}](#) quoted from another source.

Quotation punctuation (such as quotation marks) that is quoting the contents of the element must not appear immediately before, after, or inside [q^{p215}](#) elements; they will be inserted into the rendering by the user agent.

Content inside a [q^{p215}](#) element must be quoted from another source, whose address, if it has one, may be cited in the [cite](#) attribute. The source may be fictional, as when quoting characters in a novel or screenplay.

If the [cite^{p216}](#) attribute is present, it must be a [valid URL potentially surrounded by spaces^{p82}](#). To obtain the corresponding citation link, the value of the attribute must be [resolved^{p82}](#) relative to the element. User agents may allow users to follow such citation links, but they are primarily intended for private use (e.g. by server-side scripts collecting statistics about a site's use of quotations), not for readers.

The [q^{p215}](#) element must not be used in place of quotation marks that do not represent quotes; for example, it is inappropriate to use the [q^{p215}](#) element for marking up sarcastic statements.

The use of [q^{p215}](#) elements to mark up quotations is entirely optional; using explicit quotation punctuation without [q^{p215}](#) elements is just as correct.

Example

Here is a simple example of the use of the [q^{p215}](#) element:

```
<p>The man said <q>Things that are impossible just take  
longer</q>. I disagreed with him.</p>
```

Example

Here is an example with both an explicit citation link in the [q^{p215}](#) element, and an explicit citation outside:

```
<p>The W3C page <cite>About W3C</cite> says the W3C's  
mission is <q cite="http://www.w3.org/Consortium/">To lead the  
World Wide Web to its full potential by developing protocols and  
guidelines that ensure long-term growth for the Web</q>. I  
disagree with this mission.</p>
```

Example

In the following example, the quotation itself contains a quotation:

```
<p>In <cite>Example One</cite>, he writes <q>The man  
said <q>Things that are impossible just take longer</q>. I  
disagreed with him</q>. Well, I disagree even more!</p>
```

Example

In the following example, quotation marks are used instead of the [q^{p215}](#) element:

```
<p>His best argument was "I disagree", which  
I thought was laughable.</p>
```

Example

In the following example, there is no quote — the quotation marks are used to name a word. Use of the [q^{p215}](#) element in this case would be inappropriate.

```
<p>The word "ineffable" could have been used to describe the disaster resulting from the campaign's mismanagement.</p>
```

4.5.8 The `dfn` element

Categories^{p113}:

Flow content^{p115}.
Phrasing content^{p116}.
Palpable content^{p117}.

Contexts in which this element can be used^{p113}:

Where phrasing content^{p116} is expected.

Content model^{p113}:

Phrasing content^{p116}, but there must be no `dfn`^{p217} element descendants.

Tag omission in text/html^{p113}:

Neither tag is ommissible.

Content attributes^{p113}:

Global attributes^{p120}

Also, the `title`^{p217} attribute has special semantics^{p217} on this element: Full term or expansion of abbreviation.

DOM interface^{p113}:

Uses `HTMLElement`^{p112}.

The `dfn`^{p217} element represents^{p111} the defining instance of a term. The paragraph^{p118}, description list group^{p199}, or section^{p116} that is the nearest ancestor of the `dfn`^{p217} element must also contain the definition(s) for the term^{p217} given by the `dfn`^{p217} element.

Defining term: If the `dfn`^{p217} element has a `title` attribute, then the exact value of that attribute is the term being defined. Otherwise, if it contains exactly one element child node and no child `Text`^{p51} nodes, and that child element is an `abbr`^{p218} element with a `title`^{p218} attribute, then the exact value of *that* attribute is the term being defined. Otherwise, it is the exact `textContent`^{p51} of the `dfn`^{p217} element that gives the term being defined.

If the `title`^{p217} attribute of the `dfn`^{p217} element is present, then it must contain only the term being defined.

Note *The `title`^{p212} attribute of ancestor elements does not affect `dfn`^{p217} elements.*

An `a`^{p208} element that links to a `dfn`^{p217} element represents an instance of the term defined by the `dfn`^{p217} element.

Example

In the following fragment, the term "Garage Door Opener" is first defined in the first paragraph, then used in the second. In both cases, its abbreviation is what is actually displayed.

```
<p>The <dfn><abbr title="Garage Door Opener">GDO</abbr></dfn>  
is a device that allows off-world teams to open the iris.</p>  
<!-- ... later in the document: -->  
<p>Teal'c activated his <abbr title="Garage Door Opener">GDO</abbr>  
and so Hammond ordered the iris to be opened.</p>
```

With the addition of an `a`^{p208} element, the reference can be made explicit:

```
<p>The <dfn id=gdo><abbr title="Garage Door Opener">GDO</abbr></dfn>  
is a device that allows off-world teams to open the iris.</p>  
<!-- ... later in the document: -->  
<p>Teal'c activated his <a href="#gdo><abbr title="Garage Door Opener">GDO</abbr></a>  
and so Hammond ordered the iris to be opened.</p>
```

4.5.9 The `abbr` element

Categories^{p113}:

[Flow content](#)^{p115}.
[Phrasing content](#)^{p116}.
[Palpable content](#)^{p117}.

Contexts in which this element can be used^{p113}:

Where [phrasing content](#)^{p116} is expected.

Content model^{p113}:

[Phrasing content](#)^{p116}.

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes](#)^{p120}

Also, the [title](#)^{p218} attribute [has special semantics](#)^{p218} on this element: Full term or expansion of abbreviation.

DOM interface^{p113}:

Uses [HTMLElement](#)^{p112}.

The [abbr](#)^{p218} element [represents](#)^{p111} an abbreviation or acronym, optionally with its expansion. The [title](#) attribute may be used to provide an expansion of the abbreviation. The attribute, if specified, must contain an expansion of the abbreviation, and nothing else.

Example

The paragraph below contains an abbreviation marked up with the [abbr](#)^{p218} element. This paragraph [defines the term](#)^{p217} "Web Hypertext Application Technology Working Group".

```
<p>The <dfn id=whatwg><abbr  
title="Web Hypertext Application Technology Working Group">WHATWG</abbr></dfn>  
is a loose unofficial collaboration of Web browser manufacturers and  
interested parties who wish to develop new technologies designed to  
allow authors to write and deploy Applications over the World Wide  
Web.</p>
```

An alternative way to write this would be:

```
<p>The <dfn id=whatwg>Web Hypertext Application Technology  
Working Group</dfn> (<abbr  
title="Web Hypertext Application Technology Working Group">WHATWG</abbr>)  
is a loose unofficial collaboration of Web browser manufacturers and  
interested parties who wish to develop new technologies designed to  
allow authors to write and deploy Applications over the World Wide  
Web.</p>
```

Example

This paragraph has two abbreviations. Notice how only one is defined; the other, with no expansion associated with it, does not use the [abbr](#)^{p218} element.

```
<p>The  
<abbr title="Web Hypertext Application Technology Working Group">WHATWG</abbr>  
started working on HTML5 in 2004.</p>
```

Example

This paragraph links an abbreviation to its definition.

```
<p>The <a href="#whatwg"><abbr  
title="Web Hypertext Application Technology Working Group">WHATWG</abbr></a>  
community does not have much representation from Asia.</p>
```

Example

This paragraph marks up an abbreviation without giving an expansion, possibly as a hook to apply styles for abbreviations (e.g. smallcaps).

```
<p>Philip` and Dashiva both denied that they were going to  
get the issue counts from past revisions of the specification to  
backfill the <abbr>WHATWG</abbr> issue graph.</p>
```

If an abbreviation is pluralized, the expansion's grammatical number (plural vs singular) must match the grammatical number of the contents of the element.

Example

Here the plural is outside the element, so the expansion is in the singular:

```
<p>Two <abbr title="Working Group">WG</abbr>s worked on  
this specification: the <abbr>WHATWG</abbr> and the  
<abbr>HTMLWG</abbr>. </p>
```

Here the plural is inside the element, so the expansion is in the plural:

```
<p>Two <abbr title="Working Groups">WGs</abbr> worked on  
this specification: the <abbr>WHATWG</abbr> and the  
<abbr>HTMLWG</abbr>. </p>
```

Abbreviations do not have to be marked up using this element. It is expected to be useful in the following cases:

- Abbreviations for which the author wants to give expansions, where using the abbr^{b218} element with a title^{p122} attribute is an alternative to including the expansion inline (e.g. in parentheses).
- Abbreviations that are likely to be unfamiliar to the document's readers, for which authors are encouraged to either mark up the abbreviation using an abbr^{p218} element with a title^{p122} attribute or include the expansion inline in the text the first time the abbreviation is used.
- Abbreviations whose presence needs to be semantically annotated, e.g. so that they can be identified from a style sheet and given specific styles, for which the abbr^{b218} element can be used without a title^{p122} attribute.

Providing an expansion in a title^{p122} attribute once will not necessarily cause other abbr^{p218} elements in the same document with the same contents but without a title^{p122} attribute to behave as if they had the same expansion. Every abbr^{p218} element is independent.

4.5.10 The ruby element

Categories^{p113}:

Flow content^{p115}.

Phrasing content^{p116}.

Palpable content^{p117}.

Contexts in which this element can be used^{p113}:

Where phrasing content^{p116} is expected.

Content model^{p113}:

See prose.

Tag omission in text/html^{p113}:

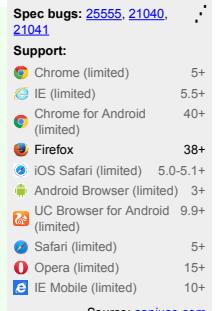

Neither tag is omissible.

Content attributes^{p113}:

Global attributes^{p120}

DOM interface^{p113}:

Uses HTMLElement^{p112}.

The `ruby`^{p219} element allows one or more spans of phrasing content to be marked with ruby annotations. Ruby annotations are short runs of text presented alongside base text, primarily used in East Asian typography as a guide for pronunciation or to include other annotations. In Japanese, this form of typography is also known as *furigana*.

The content model of `ruby`^{p219} elements consists of one or more of the following sequences:

1. One or the other of the following:
 - [Phrasing content](#)^{p116}, but with no `ruby`^{p219} elements and with no `ruby`^{b219} element descendants
 - A single `ruby`^{p219} element that itself has no `ruby`^{b219} element descendants
2. One or the other of the following:
 - One or more `rt`^{p225} elements
 - An `rp`^{p225} element followed by one or more `rt`^{p225} elements, each of which is itself followed by an `rp`^{p225} element

The `ruby`^{p219} and `rt`^{p225} elements can be used for a variety of kinds of annotations, including in particular (though by no means limited to) those described below. For more details on Japanese Ruby in particular, and how to render Ruby for Japanese, see *Requirements for Japanese Text Layout*. [\[JLREQ\]](#)^{p1150}

Note At the time of writing, CSS does not yet provide a way to fully control the rendering of the HTML `ruby`^{p219} element. It is hoped that CSS will be extended to support the styles described below in due course.

Mono-ruby for individual base characters in Japanese

One or more hiragana or katakana characters (the ruby annotation) are placed with each ideographic character (the base text). This is used to provide readings of kanji characters.

Example

```
<ruby>B<rt>annotation</ruby>
```

Example

In this example, notice how each annotation corresponds to a single base character.

```
<ruby>君<rt>< ん</rt><ruby>子<rt>し</rt>は<ruby>和<rt>わ</rt>して<ruby>同<rt>どう</rt>ぜ<rt>ず。</ruby>
```

君くん子しは和わして同どうぜず。

This example can also be written as follows, using one `ruby`^{p219} element with two segments of base text and two annotations (one for each) rather than two back-to-back `ruby`^{p219} elements each with one base text segment and annotation (as in the markup above):

```
<ruby>君<rt>< ん</rt>子<rt>し</rt>は<ruby>和<rt>わ</rt>して<ruby>同<rt>どう</rt>ぜ<rt>ず。</ruby>
```

Mono-ruby for compound words (jukugo)

This is similar to the previous case: each ideographic character in the compound word (the base text) has its reading given in hiragana or katakana characters (the ruby annotation). The difference is that the base text segments form a compound word rather than being separate from each other.

Example

```
<ruby>B<rt>annotation</rt>B<rt>annotation</ruby>
```

Example

In this example, notice again how each annotation corresponds to a single base character. In this example, each compound word (jukugo) corresponds to a single `ruby`^{b219} element.

The rendering here is expected to be that each annotation be placed over (or next to, in vertical text) the corresponding base character, with the annotations not overhanging any of the adjacent characters.

```
<ruby>鬼<rt>き</rt>門<rt>もん</rt><ruby>の<rt>方<rt>ほう</rt>角<rt>かく</rt><ruby>を<rt>凝<rt>ぎょう</rt>視<rt>し</rt></ruby>する
```

鬼き門もんの方ほう角かくを凝ぎょう視しする

Jukugo-ruby

This is semantically identical to the previous case (each individual ideographic character in the base compound word has its reading given in an annotation in hiragana or katakana characters), but the rendering is the more complicated Jukugo Ruby rendering.

Example

This is the same example as above for mono-ruby for compound words. The different rendering is expected to be achieved using different styling (e.g. in CSS), and is not shown here.

```
<ruby>鬼<rt>き</rt>門<rt>もん</rt></ruby>の<ruby>方<rt>ほう</rt>角<rt>かく</rt>がく</rt></ruby>を<ruby>凝<rt>ぎょう</rt>視<rt>し</rt></ruby>する
```

Note For more details on [Jukugo Ruby rendering](#), see Appendix F in the Requirements for Japanese Text Layout. [JLREQJ^{p1150}](#)

Group ruby for describing meanings

The annotation describes the meaning of the base text, rather than (or in addition to) the pronunciation. As such, both the base text and the annotation can be multiple characters long.

Example

```
<ruby>BASE<rt>annotation</ruby>
```

Example

Here a compound ideographic word has its corresponding katakana given as an annotation.

```
<ruby>境界面<rt>インターフェース</ruby>
```

境界面インターフェース

Example

Here a compound ideographic word has its translation in English provided as an annotation.

```
<ruby lang="ja">編集者<rt lang="en">editor</ruby>
```

編集者editor

Group ruby for Jukiji readings

A phonetic reading that corresponds to multiple base characters, because a one-to-one mapping would be difficult. (In English, the words "Colonel" and "Lieutenant" are examples of words where a direct mapping of pronunciation to individual letters is, in some dialects, rather unclear.)

Example

In this example, the name of a species of flowers has a phonetic reading provided using group ruby:

```
<ruby>紫陽花<rt>あじさい</ruby>
```

紫陽花あじさい

Text with both phonetic and semantic annotations (double-sided ruby)

Sometimes, ruby styles described above are combined.

If this results in two annotations covering the same single base segment, then the annotations can just be placed back to back.

Example

```
<ruby>BASE<rt>annotation 1<rt>annotation 2</ruby>
```

Example

```
<ruby>B<rt>a<rt>a</ruby><ruby>A<rt>a<rt>a</ruby><ruby>S<rt>a</ruby><ruby>E<rt>a<rt>a</ruby>
```

Example

In this contrived example, some symbols are given names in English and French.

```
<ruby>
  ♥ <rt> Heart <rt lang="fr"> Cœur
  ♦ <rt> Shamrock <rt lang="fr"> Trèfle
  * <rt> Star <rt lang="fr"> Étoile
</ruby>
```

In more complication situations such as following examples, a nested [ruby^{p219}](#) element is used to give the inner annotations, and then that whole [ruby^{p219}](#) is then given an annotation at the "outer" level.

Example

```
<ruby><ruby>B<rt>a</rt>A<rt>n</rt>S<rt>t</rt>E<rt>n</rt></ruby><rt>annotation</ruby>
```

Example

Here both a phonetic reading and the meaning are given in ruby annotations. The annotation on the nested `rubyp219` element gives a mono-ruby phonetic annotation for each base character, while the annotation in the `rtp225` element that is a child of the outer `rubyp219` element gives the meaning using hiragana.

```
<ruby><ruby>東<rt>とう</rt>南<rt>なん</rt></ruby><rt>たつみ</rt></ruby>の方角
```

東とう南なんたつみの方角

Example This is the same example, but the meaning is given in English instead of Japanese:

```
<ruby><ruby>東<rt>とう</rt>南<rt>なん</rt></ruby><rt lang=en>Southeast</rt></ruby>の方角
```

東とう南なんSoutheastの方角

Within a `rubyp219` element that does not have a `rubyp219` element ancestor, content is segmented and segments are placed into three categories: base text segments, annotation segments, and ignored segments. Ignored segments do not form part of the document's semantics (they consist of some [inter-element whitespace^{p113}](#) and `rpp225` elements, the latter of which are used for legacy user agents that do not support ruby at all). Base text segments can overlap (with a limit of two segments overlapping any one position in the DOM, and with any segment having an earlier start point than an overlapping segment also having an equal or later end point, and any segment have a later end point than an overlapping segment also having an equal or earlier start point). Annotation segments correspond to `rtp225` elements. Each annotation segment can be associated with a base text segment, and each base text segment can have annotation segments associated with it. (In a conforming document, each base text segment is associated with at least one annotation segment, and each annotation segment is associated with one base text segment.) A `rubyp219` element [represents^{p111}](#) the union of the segments of base text it contains, along with the mapping from those base text segments to annotation segments. Segments are described in terms of DOM ranges; annotation segment ranges always consist of exactly one element. [\[DOM\]^{p1149}](#)

At any particular time, the segmentation and categorisation of content of a `rubyp219` element is the result that would be obtained from running the following algorithm:

1. Let *base text segments* be an empty list of base text segments, each potentially with a list of base text subsegments.
2. Let *annotation segments* be an empty list of annotation segments, each potentially being associated with a base text segment or subsegment.
3. Let *root* be the `rubyp219` element for which the algorithm is being run.
4. If *root* has a `rubyp219` element ancestor, then jump to the step labeled *end*.
5. Let *current parent* be *root*.
6. Let *index* be 0.
7. Let *start index* be null.
8. Let *parent start index* be null.
9. Let *current base text* be null.
10. *Start mode*: If *index* is equal to or greater than the number of child nodes in *current parent*, then jump to the step labeled *end mode*.
11. If the *indexth* node in *current parent* is an `rtp225` or `rpp225` element, jump to the step labeled *annotation mode*.
12. Set *start index* to the value of *index*.
13. *Base mode*: If the *indexth* node in *current parent* is a `rubyp219` element, and if *current parent* is the same element as *root*, then [push a ruby level^{p223}](#) and then jump to the step labeled *start mode*.
14. If the *indexth* node in *current parent* is an `rtp225` or `rpp225` element, then [set the current base text^{p223}](#) and then jump to the step labeled *annotation mode*.
15. Increment *index* by one.
16. *Base mode post-increment*: If *index* is equal to or greater than the number of child nodes in *current parent*, then jump to the step labeled *end mode*.
17. Jump back to the step labeled *base mode*.

18. *Annotation mode*: If the *indexth* node in *current parent* is an [rt^{p225}](#) element, then [push a ruby annotation^{p223}](#) and jump to the step labeled *annotation mode increment*.
19. If the *indexth* node in *current parent* is an [rp^{p225}](#) element, jump to the step labeled *annotation mode increment*.
20. If the *indexth* node in *current parent* is not a [Text^{p51}](#) node, or is a [Text^{p51}](#) node that is not [inter-element whitespace^{p113}](#), then jump to the step labeled *base mode*.
21. *Annotation mode increment*: Let *lookahead index* be *index* plus one.
22. *Annotation mode white-space skipper*: If *lookahead index* is equal to the number of child nodes in *current parent* then jump to the step labeled *end mode*.
23. If the *lookahead indexth* node in *current parent* is an [rt^{p225}](#) element or an [rp^{p225}](#) element, then set *index* to *lookahead index* and jump to the step labeled *annotation mode*.
24. If the *lookahead indexth* node in *current parent* is not a [Text^{p51}](#) node, or is a [Text^{p51}](#) node that is not [inter-element whitespace^{p113}](#), then jump to the step labeled *base mode* (without further incrementing *index*, so the [inter-element whitespace^{p113}](#) seen so far becomes part of the next base text segment).
25. Increment *lookahead index* by one.
26. Jump to the step labeled *annotation mode white-space skipper*.
27. *End mode*: If *current parent* is not the same element as *root*, then [pop a ruby level^{p223}](#) and jump to the step labeled *base mode post-increment*.
28. *End*: Return *base text segments* and *annotation segments*. Any content of the [ruby^{p219}](#) element not described by segments in either of those lists is implicitly in an *ignored segment*.

When the steps above say to **set the current base text**, it means to run the following steps at that point in the algorithm:

1. Let *text range* be a DOM range whose [start^{p51}](#) is the [boundary point^{p51}](#) (*current parent*, *start index*) and whose [end^{p51}](#) is the [boundary point^{p51}](#) (*current parent*, *index*).
2. Let *new text segment* be a base text segment described by the range *annotation range*.
3. Add *new text segment* to *base text segments*.
4. Let *current base text* be *new text segment*.
5. Let *start index* be null.

When the steps above say to **push a ruby level**, it means to run the following steps at that point in the algorithm:

1. Let *current parent* be the *indexth* node in *current parent*.
2. Let *index* be 0.
3. Set *saved start index* to the value of *start index*.
4. Let *start index* be null.

When the steps above say to **pop a ruby level**, it means to run the following steps at that point in the algorithm:

1. Let *index* be the position of *current parent* in *root*.
2. Let *current parent* be *root*.
3. Increment *index* by one.
4. Set *start index* to the value of *saved start index*.
5. Let *saved start index* be null.

When the steps above say to **push a ruby annotation**, it means to run the following steps at that point in the algorithm:

1. Let *rt* be the [rt^{p225}](#) element that is the *indexth* node of *current parent*.

2. Let *annotation range* be a DOM range whose `startp51` is the `boundary pointp51` (*current parent, index*) and whose `endp51` is the `boundary pointp51` (*current parent, index* plus one) (i.e. that contains only *rt*).
3. Let *new annotation segment* be an annotation segment described by the range *annotation range*.
4. If *current base text* is not null, associate *new annotation segment* with *current base text*.
5. Add *new annotation segment* to *annotation segments*.

Example

In this example, each ideograph in the Japanese text 漢字 is annotated with its reading in hiragana.

```
...
<ruby>漢<rt>かん</rt>字<rt>じ</rt></ruby>
...
```

This might be rendered as:

かんじ
... 漢字 ...

Example

In this example, each ideograph in the traditional Chinese text 漢字 is annotated with its bopomofo reading.

```
<ruby>漢<rt>ㄏㄢˋ</rt>字<rt>ㄔㄧˋ</rt></ruby>
```

This might be rendered as:

ㄏㄢˋ
ㄔㄧˋ
... 漢字 ...

Example

In this example, each ideograph in the simplified Chinese text 汉字 is annotated with its pinyin reading.

```
...<ruby>汉<rt>hàn</rt>字<rt>zì</rt></ruby>...
```

This might be rendered as:

hàn zì
... 汉字 ...

Example

In this more contrived example, the acronym "HTML" has four annotations: one for the whole acronym, briefly describing what it is, one for the letters "HT" expanding them to "Hypertext", one for the letter "M" expanding it to "Markup", and one for the letter "L" expanding it to "Language".

```
<ruby>
<ruby>HT<rt>Hypertext</rt>M<rt>Markup</rt>L<rt>Language</rt></ruby>
<rt>An abstract language for describing documents and applications
</ruby>
```

4.5.11 The `rt` element

Categories^{p113}:

None.

Contexts in which this element can be used^{p113}:

As a child of a `ruby`^{p219} element.

Content model^{p113}:

[Phrasing content](#)^{p116}.

Tag omission in text/html^{p113}:

An `rt`^{p225} element's [end tag](#)^{p944} can be omitted if the `rt`^{p225} element is immediately followed by an `rt`^{p225} or `rp`^{p225} element, or if there is no more content in the parent element.

Content attributes^{p113}:

[Global attributes](#)^{p120}.

DOM interface^{p113}:

Uses `HTMLElement`^{p112}.

The `rt`^{p225} element marks the ruby text component of a ruby annotation. When it is the child of a `ruby`^{p219} element, it doesn't [represent](#)^{p111} anything itself, but the `ruby`^{p219} element uses it as part of determining what it [represents](#)^{p111}.

An `rt`^{p225} element that is not a child of a `ruby`^{p219} element [represents](#)^{p111} the same thing as its children.

4.5.12 The `rp` element

Categories^{p113}:

None.

Contexts in which this element can be used^{p113}:

As a child of a `ruby`^{p219} element, either immediately before or immediately after an `rt`^{p225} element.

Content model^{p113}:

[Phrasing content](#)^{p116}.

Tag omission in text/html^{p113}:

An `rp`^{p225} element's [end tag](#)^{p944} can be omitted if the `rp`^{p225} element is immediately followed by an `rt`^{p225} or `rp`^{p225} element, or if there is no more content in the parent element.

Content attributes^{p113}:

[Global attributes](#)^{p120}.

DOM interface^{p113}:

Uses `HTMLElement`^{p112}.

The `rp`^{p225} element can be used to provide parentheses or other content around a ruby text component of a ruby annotation, to be shown by user agents that don't support ruby annotations.

An `rp`^{p225} element that is a child of a `ruby`^{p219} element [represents](#)^{p111} nothing. An `rp`^{p225} element whose parent element is not a `ruby`^{p219} element [represents](#)^{p111} its children.

Example

The example above, in which each ideograph in the text 漢字 is annotated with its phonetic reading, could be expanded to use `rp`^{p225} so that in legacy user agents the readings are in parentheses:

```
...
<ruby>漢<rp> (</rp><rt>かん</rt><rp>) </rp>字<rp> (</rp><rt> し </rt><rp>) </rp></ruby>
...
```

In conforming user agents the rendering would be as above, but in user agents that do not support ruby, the rendering would be:

Example

When there are multiple annotations for a segment, [rp^{p225}](#) elements can also be placed between the annotations. Here is another copy of an earlier contrived example showing some symbols with names given in English and French, but this time with [rp^{p225}](#) elements as well:

```
<ruby>
  ♥<rp>: </rp><rt>Heart</rt><rp>, </rp><rt lang=fr>Cœur</rt><rp>. </rp>
  ♀<rp>: </rp><rt>Shamrock</rt><rp>, </rp><rt lang=fr>Trèfle</rt><rp>. </rp>
  ★<rp>: </rp><rt>Star</rt><rp>, </rp><rt lang=fr>Étoile</rt><rp>. </rp>
</ruby>
```

This would make the example render as follows in non-ruby-capable user agents:

♥: Heart, Cœur. ♀: Shamrock, Trèfle. ★: Star, Étoile.

4.5.13 The `data` element

Categories^{p113}:

[Flow content](#)^{p115}.

[Phrasing content](#)^{p116}.

[Palpable content](#)^{p117}.

Contexts in which this element can be used^{p113}:

Where [phrasing content](#)^{p116} is expected.

Content model^{p113}:

[Phrasing content](#)^{p116}.

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes](#)^{p120}

[value](#)^{p226} — Machine-readable value

DOM interface^{p113}:

IDL	<pre>interface HTMLDataElement : HTMLElement { attribute DOMString value; };</pre>
-----	--

The [data](#)^{p226} element [represents](#)^{p111} its contents, along with a machine-readable form of those contents in the [value](#)^{p226} attribute.

The [value](#) attribute must be present. Its value must be a representation of the element's contents in a machine-readable format.

Note When the value is date- or time-related, the more specific [time](#)^{p227} element can be used instead.

The element can be used for several purposes.

When combined with microformats or the [microdata attributes](#)^{p683} defined in this specification, the element serves to provide both a machine-readable value for the purposes of data processors, and a human-readable value for the purposes of rendering in a Web browser. In this case, the format to be used in the [value](#)^{p226} attribute is determined by the microformats or microdata vocabulary in use.

The element can also, however, be used in conjunction with scripts in the page, for when a script has a literal value to store alongside a human-readable value. In such cases, the format to be used depends only on the needs of the script. (The [data-*](#)^{p128} attributes can also be useful in such situations.)

The [value](#) IDL attribute must [reflect](#)^{p88} the content attribute of the same name.

Example

Here, a short table has its numeric values encoded using [data](#)^{p226} so that the [table sorting model](#)^{p422} can provide a sorting mechanism on each column, despite the numbers being presented in textual form in one column and in a decomposed form in another.

```
<table sortable>
<thead> <tr> <th> Game <th> Corporations <th> Map Size
<tbody>
<tr> <td> 1830 <td> <data value="8">Eight</data> <td> <data value="93">19+74 hexes (93
total)</data>
<tr> <td> 1856 <td> <data value="11">Eleven</data> <td> <data value="99">12+87 hexes (99
total)</data>
<tr> <td> 1870 <td> <data value="10">Ten</data> <td> <data value="149">4+145 hexes (149
total)</data>
</tbody>
```

4.5.14 The `time` element

Categories^{p113}:

[Flow content](#)^{p115}.
[Phrasing content](#)^{p116}.
[Palpable content](#)^{p117}.

Contexts in which this element can be used^{p113}:

Where [phrasing content](#)^{p116} is expected.

Content model^{p113}:

[Phrasing content](#)^{p116}.

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes](#)^{p120}
[datetime](#)^{p227} — Machine-readable value

DOM interface^{p113}:

```
IDL interface HTMLTimeElement : HTMLElement {
    attribute DOMString dateTime;
};
```

The [time](#)^{p227} element [represents](#)^{p111} its contents, along with a machine-readable form of those contents in the [datetime](#)^{p227} attribute. The kind of content is limited to various kinds of dates, times, time-zone offsets, and durations, as described below.

The [datetime](#) attribute may be present. If present, its value must be a representation of the element's contents in a machine-readable format.

A [time](#)^{p227} element that does not have a [datetime](#)^{p227} content attribute must not have any element descendants.

The [datetime value](#) of a [time](#)^{p227} element is the value of the element's [datetime](#)^{p227} content attribute, if it has one, or the element's [textContent](#)^{p51}, if it does not.

The [datetime value](#)^{p227} of a [time](#)^{p227} element must match one of the following syntaxes.

A [valid month string](#)^{p67}

Example <time>2011-11</time>

A [valid date string](#)^{p67}

Example <time>2011-11-18</time>

A valid yearless date string^{p68}

Example <time>11-18</time>

A valid time string^{p69}

Example <time>14:54</time>

Example <time>14:54:39</time>

Example <time>14:54:39.929</time>

A valid local date and time string^{p70}

Example <time>2011-11-18T14:54</time>

Example <time>2011-11-18T14:54:39</time>

Example <time>2011-11-18T14:54:39.929</time>

Example <time>2011-11-18 14:54</time>

Example <time>2011-11-18 14:54:39</time>

Example <time>2011-11-18 14:54:39.929</time>

Note Times with dates but without a time zone offset are useful for specifying events that are observed at the same specific time in each time zone, throughout a day. For example, the 2020 new year is celebrated at 2020-01-01 00:00 in each time zone, not at the same precise moment across all time zones. For events that occur at the same time across all time zones, for example a videoconference meeting, a valid global date and time string^{p72} is likely more useful.

A valid time-zone offset string^{p71}

Example <time>Z</time>

Example <time>+0000</time>

Example <time>+00:00</time>

Example <time>-0800</time>

Example <time>-08:00</time>

Note For times without dates (or times referring to events that recur on multiple dates), specifying the geographic location that controls the time is usually more useful than specifying a time zone offset, because geographic locations change time zone offsets with daylight savings time. In some cases, geographic locations even change time zone, e.g. when the boundaries of those time zones are redrawn, as happened with Samoa at the end of 2011. There exists a time zone database that describes the boundaries of time zones and what rules apply within each such zone, known as the time zone database. [ITZDATABASE](#)^{p1153}

A valid global date and time string^{p72}

Example <time>2011-11-18T14:54Z</time>

Example <time>2011-11-18T14:54:39Z</time>

Example <time>2011-11-18T14:54:39.929Z</time>

Example <time>2011-11-18T14:54+0000</time>

Example <time>2011-11-18T14:54:39+0000</time>

Example <time>2011-11-18T14:54:39.929+0000</time>

Example <time>2011-11-18T14:54:00:00</time>

Example <time>2011-11-18T14:54:39+00:00</time>

Example <time>2011-11-18T14:54:39.929+00:00</time>

Example <time>2011-11-18T06:54-0800</time>

Example <time>2011-11-18T06:54:39-0800</time>

Example <time>2011-11-18 06:54-08:00</time>

Example <time>2011-11-18 06:54:39-08:00</time>

Example <time>2011-11-18 06:54:39.929-08:00</time>

Note Times with dates and a time zone offset are useful for specifying specific events, or recurring virtual events where the time is not anchored to a specific geographic location. For example, the precise time of an asteroid impact, or a particular meeting in a series of meetings held at 1400 UTC every day, regardless of whether any particular part of the world is observing daylight savings time or not. For events where the precise time varies by the local time zone offset of a specific geographic location, a [valid local date and time string^{p70}](#) combined with that geographic location is likely more useful.

A [valid week string^{p74}](#)

Example <time>2011-W47</time>

Four or more [ASCII digits^{p58}](#), at least one of which is not U+0030 DIGIT ZERO (0)

Example <time>2011</time>

Example <time>0001</time>

A [valid duration string^{p74}](#)

Example <time>PT4H18M3S</time>

Example <time>4h 18m 3s</time>

The **machine-readable equivalent of the element's contents** must be obtained from the element's [datetime value^{p227}](#) by using the following algorithm:

1. If [parsing a month string^{p67}](#) from the element's [datetime value^{p227}](#) returns a [month^{p67}](#), that is the machine-readable equivalent; abort these steps.
2. If [parsing a date string^{p68}](#) from the element's [datetime value^{p227}](#) returns a [date^{p67}](#), that is the machine-readable equivalent; abort these steps.
3. If [parsing a yearless date string^{p68}](#) from the element's [datetime value^{p227}](#) returns a [yearless date^{p68}](#), that is the machine-readable equivalent; abort these steps.
4. If [parsing a time string^{p69}](#) from the element's [datetime value^{p227}](#) returns a [time^{p69}](#), that is the machine-readable equivalent; abort these steps.
5. If [parsing a local date and time string^{p70}](#) from the element's [datetime value^{p227}](#) returns a [local date and time^{p70}](#), that is the machine-readable equivalent; abort these steps.
6. If [parsing a time-zone offset string^{p71}](#) from the element's [datetime value^{p227}](#) returns a [time-zone offset^{p71}](#), that is the machine-readable equivalent; abort these steps.
7. If [parsing a global date and time string^{p73}](#) from the element's [datetime value^{p227}](#) returns a [global date and time^{p72}](#), that is the machine-readable equivalent; abort these steps.
8. If [parsing a week string^{p74}](#) from the element's [datetime value^{p227}](#) returns a [week^{p73}](#), that is the machine-readable equivalent; abort these steps.
9. If the element's [datetime value^{p227}](#) consists of only [ASCII digits^{p58}](#), at least one of which is not U+0030 DIGIT ZERO (0), then the machine-readable equivalent is the base-ten interpretation of those digits, representing a year; abort these steps.
10. If [parsing a duration string^{p76}](#) from the element's [datetime value^{p227}](#) returns a [duration^{p74}](#), that is the machine-readable equivalent; abort these steps.
11. There is no machine-readable equivalent.

Note *The algorithms referenced above are intended to be designed such that for any arbitrary string s, only one of the algorithms returns a value. A more efficient approach might be to create a single algorithm that parses all these data types in one pass; developing such an algorithm is left as an exercise to the reader.*

The **dateTime** IDL attribute must [reflect^{p88}](#) the element's [datetime^{p227}](#) content attribute.

Example

The [time^{p227}](#) element can be used to encode dates, for example in microformats. The following shows a hypothetical way of encoding an event using a variant on hCalendar that uses the [time^{p227}](#) element:

```
<div class="vevent">
  <a class="url" href="http://www.web2con.com/">http://www.web2con.com/</a>
  <span class="summary">Web 2.0 Conference</span>:
  <time class="dtstart" datetime="2005-10-05">October 5</time> -
  <time class="dtend" datetime="2005-10-07">7</time>,
  at the <span class="location">Argent Hotel, San Francisco, CA</span>
</div>
```

Example

Here, a fictional microdata vocabulary based on the Atom vocabulary is used with the [time^{p227}](#) element to mark up a blog post's publication date.

```
<article itemscope itemtype="http://n.example.org/rfc4287">
  <h1 itemprop="title">Big tasks</h1>
  <footer>Published <time itemprop="published" datetime="2009-08-29">two days ago</time>. </footer>
  <p itemprop="content">Today, I went out and bought a bike for my kid.</p>
</article>
```

Example

In this example, another article's publication date is marked up using [time^{p227}](#), this time using the schema.org microdata vocabulary:

```

<article itemscope itemtype="http://schema.org/BlogPosting">
  <h1 itemprop="headline">Small tasks</h1>
  <footer>Published <time itemprop="datePublished"
  datetime="2009-08-30">yesterday</time>. </footer>
  <p itemprop="articleBody">I put a bike bell on his bike.</p>
</article>

```

Example

In the following snippet, the [time^{p227}](#) element is used to encode a date in the ISO8601 format, for later processing by a script:

```
<p>Our first date was <time datetime="2006-09-23">a Saturday</time>.</p>
```

In this second snippet, the value includes a time:

```
<p>We stopped talking at <time datetime="2006-09-24T05:00-07:00">5am the next morning</time>.</p>
```

A script loaded by the page (and thus privy to the page's internal convention of marking up dates and times using the [time^{p227}](#) element) could scan through the page and look at all the [time^{p227}](#) elements therein to create an index of dates and times.

Example

For example, this element conveys the string "Tuesday" with the additional semantic that the 18th of November 2011 is the meaning that corresponds to "Tuesday":

```
Today is <time datetime="2011-11-18">Tuesday</time>.
```

Example

In this example, a specific time in the Pacific Standard Time timezone is specified:

```
Your next meeting is at <time datetime="2011-11-18T15:00-08:00">3pm</time>.
```

4.5.15 The `code` element

Categories^{p113}:

[Flow content^{p115}](#).
[Phrasing content^{p116}](#).
[Palpable content^{p117}](#).

Contexts in which this element can be used^{p113}:

Where [phrasing content^{p116}](#) is expected.

Content model^{p113}:

[Phrasing content^{p116}](#).

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes^{p120}](#)

DOM interface^{p113}:

Uses [HTMLElement^{p112}](#).

The [code^{p231}](#) element [represents^{p111}](#) a fragment of computer code. This could be an XML element name, a file name, a computer program, or any other string that a computer would recognize.

There is no formal way to indicate the language of computer code being marked up. Authors who wish to mark [code^{p231}](#) elements with the language used, e.g. so that syntax highlighting scripts can use the right rules, can use the [class^{p128}](#) attribute, e.g. by adding a class prefixed with "language-" to the element.

Example

The following example shows how the element can be used in a paragraph to mark up element names and computer code, including punctuation.

<p>The <code>code</code> element represents a fragment of computer code.</p>

<p>When you call the <code>activate()</code> method on the <code>robotSnowman</code> object, the eyes glow.</p>

<p>The example below uses the <code>begin</code> keyword to indicate the start of a statement block. It is paired with an <code>end</code> keyword, which is followed by the <code>.</code> punctuation character (full stop) to indicate the end of the program.</p>

Example

The following example shows how a block of code could be marked up using the [pre^{p191}](#) and [code^{p231}](#) elements.

```
<pre><code class="language-pascal">var i: Integer;
begin
    i := 1;
end.</code></pre>
```

A class is used in that example to indicate the language used.

Note

See the [pre^{p191}](#) element for more details.

4.5.16 The `var` element

Categories^{p113}:

[Flow content^{p115}](#).

[Phrasing content^{p116}](#).

[Palpable content^{p117}](#).

Contexts in which this element can be used^{p113}:

Where [phrasing content^{p116}](#) is expected.

Content model^{p113}:

[Phrasing content^{p116}](#).

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes^{p120}](#)

DOM interface^{p113}:

Uses [HTMLElement^{p112}](#).

The [var^{p232}](#) element [represents^{p111}](#) a variable. This could be an actual variable in a mathematical expression or programming context, an identifier representing a constant, a symbol identifying a physical quantity, a function parameter, or just be a term used as a placeholder in prose.

Example

In the paragraph below, the letter "n" is being used as a variable in prose:

```
<p>If there are <var>n</var> pipes leading to the ice
cream factory then I expect at least <em>least</em> <var>n</var>
flavors of ice cream to be available for purchase!</p>
```

For mathematics, in particular for anything beyond the simplest of expressions, MathML is more appropriate. However, the [var^{p232}](#) element can still be used to refer to specific variables that are then mentioned in MathML expressions.

Example

In this example, an equation is shown, with a legend that references the variables in the equation. The expression itself is marked up with MathML, but the variables are mentioned in the figure's legend using [var^{p232}](#).

```

<figure>
  <math>
    <mi>a</mi>
    <mo>=</mo>
    <msqrt>
      <msup><mi>b</mi><mn>2</mn></msup>
      <mi>+</mi>
      <msup><mi>c</mi><mn>2</mn></msup>
    </msqrt>
  </math>
  <figcaption>
    Using Pythagoras' theorem to solve for the hypotenuse <var>a</var> of
    a triangle with sides <var>b</var> and <var>c</var>
  </figcaption>
</figure>

```

Example

Here, the equation describing mass-energy equivalence is used in a sentence, and the `<var>` element is used to mark the variables and constants in that equation:

<p>Then he turned to the blackboard and picked up the chalk. After a few moment's thought, he wrote $E = mc^2$. The teacher looked pleased.</p>

4.5.17 The `samp` element

Categories^{p113}:

[Flow content](#)^{p115}.
[Phrasing content](#)^{p116}.
[Palpable content](#)^{p117}.

Contexts in which this element can be used^{p113}:

Where [phrasing content](#)^{p116} is expected.

Content model^{p113}:

[Phrasing content](#)^{p116}.

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes](#)^{p120}

DOM interface^{p113}:

Uses [HTMLElement](#)^{p112}.

The `samp`^{p233} element [represents](#)^{p111} sample or quoted output from another program or computing system.

Note See the `pre`^{p191} and `kbd`^{p234} elements for more details.

Note This element can be contrasted with the `output`^{p516} element, which can be used to provide immediate output in a Web application.

Example

This example shows the `samp`^{p233} element being used inline:

<p>The computer said <samp>Too much cheese in tray
two</samp> but I didn't know what that meant.</p>

Example

This second example shows a block of sample output. Nested `samp`^{p233} and `kbd`^{p234} elements allow for the styling of specific elements of the sample output using a style sheet. There's also a few parts of the `samp`^{p233} that are annotated with even more detailed markup, to enable very precise styling. To achieve this, `span`^{p242} elements are used.

```
<pre><samp><span class="prompt">jdoe@mowmow:~$</span> <kbd>ssh demo.example.com</kbd>
Last login: Tue Apr 12 09:10:17 2005 from mowmow.example.com on pts/1
Linux demo 2.6.10-grsec+gg3+e+fhs6b+nfs+gr0501+++p3+c4a+gr2b-reslog-v6.189 #1 SMP Tue Feb 1
11:22:36 PST 2005 i686 unknown

<span class="prompt">jdoe@demo:~$</span> <span class="cursor">_</span></samp></pre>
```

4.5.18 The `kbd` element

Categories^{p113}:

[Flow content](#)^{p115}.
[Phrasing content](#)^{p116}.
[Palpable content](#)^{p117}.

Contexts in which this element can be used^{p113}:

Where [phrasing content](#)^{p116} is expected.

Content model^{p113}:

[Phrasing content](#)^{p116}.

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes](#)^{p120}

DOM interface^{p113}:

Uses [HTMLElement](#)^{p112}.

The `kbd`^{p234} element [represents](#)^{p111} user input (typically keyboard input, although it may also be used to represent other input, such as voice commands).

When the `kbd`^{p234} element is nested inside a `samp`^{p233} element, it represents the input as it was echoed by the system.

When the `kbd`^{p234} element [contains](#)^{p233} a `samp`^{p233} element, it represents input based on system output, for example invoking a menu item.

When the `kbd`^{p234} element is nested inside another `kbd`^{p234} element, it represents an actual key or other single unit of input as appropriate for the input mechanism.

Example

Here the `kbd`^{p234} element is used to indicate keys to press:

```
<p>To make George eat an apple, press <kbd><kbd>Shift</kbd>+<kbd>F3</kbd></kbd></p>
```

In this second example, the user is told to pick a particular menu item. The outer `kbd`^{p234} element marks up a block of input, with the inner `kbd`^{p234} elements representing each individual step of the input, and the `samp`^{p233} elements inside them indicating that the steps are input based on something being displayed by the system, in this case menu labels:

```
<p>To make George eat an apple, select
  <kbd><kbd><samp>File</samp></kbd>|<kbd><samp>Eat Apple...</samp></kbd></kbd>
</p>
```

Such precision isn't necessary; the following is equally fine:

```
<p>To make George eat an apple, select <kbd>File | Eat Apple...</kbd></p>
```

4.5.19 The **sub** and **sup** elements

Categories^{p113}:

[Flow content](#)^{p115}.
[Phrasing content](#)^{p116}.
[Palpable content](#)^{p117}.

Contexts in which this element can be used^{p113}:

Where [phrasing content](#)^{p116} is expected.

Content model^{p113}:

[Phrasing content](#)^{p116}.

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes](#)^{p120}

DOM interface^{p113}:

Use [HTMLElement](#)^{p112}.

The [sup](#)^{p235} element [represents](#)^{p111} a superscript and the [sub](#)^{p235} element [represents](#)^{p111} a subscript.

These elements must be used only to mark up typographical conventions with specific meanings, not for typographical presentation for presentation's sake. For example, it would be inappropriate for the [sub](#)^{p235} and [sup](#)^{p235} elements to be used in the name of the LaTeX document preparation system. In general, authors should use these elements only if the *absence* of those elements would change the meaning of the content.

In certain languages, superscripts are part of the typographical conventions for some abbreviations.

Example

```
<p>The most beautiful women are
<span lang="fr"><abbr>M<sup>lle</sup></abbr> Gwendoline</span> and
<span lang="fr"><abbr>M<sup>me</sup></abbr> Denise</span>.</p>
```

The [sub](#)^{p235} element can be used inside a [var](#)^{p232} element, for variables that have subscripts.

Example

Here, the [sub](#)^{p235} element is used to represent the subscript that identifies the variable in a family of variables:

```
<p>The coordinate of the <var>i</var>th point is
(<var>x<sub>i</sub></var>, <var>y<sub>i</sub></var>). .
For example, the 10th point has coordinate
(<var>x<sub>10</sub></var>, <var>y<sub>10</sub></var>).</p>
```

Mathematical expressions often use subscripts and superscripts. Authors are encouraged to use MathML for marking up mathematics, but authors may opt to use [sub](#)^{p235} and [sup](#)^{p235} if detailed mathematical markup is not desired. [\[MATHML\]](#)^{p1151}

Example

```
<var>E</var>=<var>m</var><var>c</var><sup>2</sup>
f(<var>x</var>, <var>n</var>) = log<sub>4</sub><var>x</var><sup>n</sup>
```

4.5.20 The **i** element

Categories^{p113}:

[Flow content](#)^{p115}.
[Phrasing content](#)^{p116}.
[Palpable content](#)^{p117}.

Contexts in which this element can be used^{p113}:

Where [phrasing content](#)^{p116} is expected.

Content model^{p113}:

[Phrasing content^{p116}.](#)

Tag omission in text/html^{p113}:

Neither tag is omissionable.

Content attributes^{p113}:

[Global attributes^{p120}](#)

DOM interface^{p113}:

Uses [HTMLElement^{p112}](#).

The [*i*^{p235}](#) element [represents^{p111}](#) a span of text in an alternate voice or mood, or otherwise offset from the normal prose in a manner indicating a different quality of text, such as a taxonomic designation, a technical term, an idiomatic phrase from another language, transliteration, a thought, or a ship name in Western texts.

Terms in languages different from the main text should be annotated with [*lang*^{p123}](#) attributes (or, in XML, [lang attributes in the XML namespace^{p123}](#)).

Example

The examples below show uses of the [*i*^{p235}](#) element:

```
<p>The <i class="taxonomy">Felis silvestris catus</i> is cute.</p>
<p>The term <i>prose content</i> is defined above.</p>
<p>There is a certain <i lang="fr">je ne sais quoi</i> in the air.</p>
```

In the following example, a dream sequence is marked up using [*i*^{p235}](#) elements.

```
<p>Raymond tried to sleep.</p>
<p><i>The ship sailed away on Thursday</i>, he
dreamt. <i>The ship had many people aboard, including a beautiful
princess called Carey. He watched her, day-in, day-out, hoping she
would notice him, but she never did.</i></p>
<p><i>Finally one night he picked up the courage to speak with
her--</i></p>
<p>Raymond woke with a start as the fire alarm rang out.</p>
```

Authors can use the [*class*^{p128}](#) attribute on the [*i*^{p235}](#) element to identify why the element is being used, so that if the style of a particular use (e.g. dream sequences as opposed to taxonomic terms) is to be changed at a later date, the author doesn't have to go through the entire document (or series of related documents) annotating each use.

Authors are encouraged to consider whether other elements might be more applicable than the [*i*^{p235}](#) element, for instance the [*em*^{p210}](#) element for marking up stress emphasis, or the [*dfn*^{p217}](#) element to mark up the defining instance of a term.

Note *Style sheets can be used to format [*i*^{p235}](#) elements, just like any other element can be restyled. Thus, it is not the case that content in [*i*^{p235}](#) elements will necessarily be italicized.*

4.5.21 The **b** element

Categories^{p113}:

[Flow content^{p115}.](#)

[Phrasing content^{p116}.](#)

[Palpable content^{p117}.](#)

Contexts in which this element can be used^{p113}:

Where [phrasing content^{p116}](#) is expected.

Content model^{p113}:

[Phrasing content^{p116}.](#)

Tag omission in text/html^{p113}:

Neither tag is ommissible.

Content attributes^{p113}:

[Global attributes^{p120}](#)

DOM interface^{p113}:

Uses [HTMLElement^{p112}](#).

The **b^{p236}** element [represents^{p111}](#) a span of text to which attention is being drawn for utilitarian purposes without conveying any extra importance and with no implication of an alternate voice or mood, such as key words in a document abstract, product names in a review, actionable words in interactive text-driven software, or an article lede.

Example

The following example shows a use of the **b^{p236}** element to highlight key words without marking them up as important:

```
<p>The <b>frobonitor</b> and <b>barbinator</b> components are fried.</p>
```

Example

In the following example, objects in a text adventure are highlighted as being special by use of the **b^{p236}** element.

```
<p>You enter a small room. Your <b>sword</b> glows  
brighter. A <b>rat</b> scurries past the corner wall.</p>
```

Example

Another case where the **b^{p236}** element is appropriate is in marking up the lede (or lead) sentence or paragraph. The following example shows how a [BBC article about kittens adopting a rabbit as their own](#) could be marked up:

```
<article>  
  <h2>Kittens 'adopted' by pet rabbit</h2>  
  <p><b class="lede">Six abandoned kittens have found an  
  unexpected new mother figure – a pet rabbit.</b></p>  
  <p>Veterinary nurse Melanie Humble took the three-week-old  
  kittens to her Aberdeen home.</p>  
  [...]
```

As with the i^{p235} element, authors can use the class^{p128} attribute on the **b^{p236}** element to identify why the element is being used, so that if the style of a particular use is to be changed at a later date, the author doesn't have to go through annotating each use.

The **b^{p236}** element should be used as a last resort when no other element is more appropriate. In particular, headings should use the h1^{p168} to h6^{p168} elements, stress emphasis should use the em^{p210} element, importance should be denoted with the strong^{p211} element, and text marked or highlighted should use the mark^{p238} element.

Example

The following would be *incorrect* usage:

```
<p><b>WARNING!</b> Do not frob the barbinator!</p>
```

In the previous example, the correct element to use would have been strong^{p211}, not **b^{p236}**.

Note *Style sheets can be used to format **b^{p236}** elements, just like any other element can be restyled. Thus, it is not the case that content in **b^{p236}** elements will necessarily be boldened.*

4.5.22 The **u** element

Categories^{p113}:

[Flow content^{p115}](#).

[Phrasing content^{p116}](#).

[Palpable content^{p117}](#).

Contexts in which this element can be used^{p113}:

Where [phrasing content^{p116}](#) is expected.

Content model^{p113}:

[Phrasing content^{p116}](#).

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes^{p120}](#)

DOM interface^{p113}:

Uses [HTMLElement^{p112}](#).

The ^{p237} element [represents^{p111}](#) a span of text with an unarticulated, though explicitly rendered, non-textual annotation, such as labeling the text as being a proper name in Chinese text (a Chinese proper name mark), or labeling the text as being misspelt.

In most cases, another element is likely to be more appropriate: for marking stress emphasis, the ^{p210} element should be used; for marking key words or phrases either the ^{p236} element or the ^{p238} element should be used, depending on the context; for marking book titles, the ^{p214} element should be used; for labeling text with explicit textual annotations, the ^{p219} element should be used; for labeling ship names in Western texts, the ^{p235} element should be used.

Note *The default rendering of the ^{p237} element in visual presentations clashes with the conventional rendering of hyperlinks (underlining). Authors are encouraged to avoid using the ^{p237} element where it could be confused for a hyperlink.*

Example

In this example, a ^{p237} element is used to mark a word as misspelt:

```
<p>The <u>see</u> is full of fish.</p>
```

4.5.23 The ^{p238} element

Categories^{p113}:

[Flow content^{p115}](#).

[Phrasing content^{p116}](#).

[Palpable content^{p117}](#).

Contexts in which this element can be used^{p113}:

Where [phrasing content^{p116}](#) is expected.

Content model^{p113}:

[Phrasing content^{p116}](#).

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes^{p120}](#)

DOM interface^{p113}:

Uses [HTMLElement^{p112}](#).

The ^{p238} element [represents^{p111}](#) a run of text in one document marked or highlighted for reference purposes, due to its relevance in another context. When used in a quotation or other block of text referred to from the prose, it indicates a highlight that was not originally present but which has been added to bring the reader's attention to a part of the text that might not have been considered important by the original author when the block was originally written, but which is now under previously unexpected scrutiny. When used in the main prose of a document, it indicates a part of the document that has been highlighted due to its likely relevance to the user's current activity.

Example

This example shows how the `mark`^{p238} element can be used to bring attention to a particular part of a quotation:

```
<p lang="en-US">Consider the following quote:</p>
<blockquote lang="en-GB">
  <p>Look around and you will find, no-one's really
  <mark>colour</mark> blind.</p>
</blockquote>
<p lang="en-US">As we can tell from the <em>spelling</em> of the word,
the person writing this quote is clearly not American.</p>
```

(If the goal was to mark the element as misspelt, however, the `u`^{p237} element, possibly with a class, would be more appropriate.)

Example

Another example of the `mark`^{p238} element is highlighting parts of a document that are matching some search string. If someone looked at a document, and the server knew that the user was searching for the word "kitten", then the server might return the document with one paragraph modified as follows:

```
<p>I also have some <mark>kitten</mark>s who are visiting me
these days. They're really cute. I think they like my garden! Maybe I
should adopt a <mark>kitten</mark>.</p>
```

Example

In the following snippet, a paragraph of text refers to a specific part of a code fragment.

```
<p>The highlighted part below is where the error lies:</p>
<pre><code>var i: Integer;
begin
  i := <mark>1.1</mark>;
end.</code></pre>
```

This is separate from *syntax highlighting*, for which `span`^{p242} is more appropriate. Combining both, one would get:

```
<p>The highlighted part below is where the error lies:</p>
<pre><code><span class="keyword">var </span> <span class="ident">i</span>: <span
class="type">Integer</span>;
<span class="keyword">begin </span>
  <span class="ident">i</span> := <span class="literal"><mark>1.1</mark></span>;
<span class="keyword">end </span>.</code></pre>
```

Example

This is another example showing the use of `mark`^{p238} to highlight a part of quoted text that was originally not emphasized. In this example, common typographic conventions have led the author to explicitly style `mark`^{p238} elements in quotes to render in italics.

```
<article>
  <style scoped>
    blockquote mark, q mark {
      font: inherit; font-style: italic;
      text-decoration: none;
      background: transparent; color: inherit;
    }
    .bubble em {
      font: inherit; font-size: larger;
      text-decoration: underline;
    }
  </style>
  <h1>She knew</h1>
  <p>Did you notice the subtle joke in the joke on panel 4?</p>
  <blockquote>
    <p class="bubble">I didn't <em>want</em> to believe. <mark>Of course
    on some level I realised it was a known-plaintext attack.</mark> But I
    couldn't admit it until I saw for myself.</p>
  </blockquote>
```

```
<p>(Emphasis mine.) I thought that was great. It's so pedantic, yet it  
explains everything neatly.</p>  
</article>
```

Note, incidentally, the distinction between the [em^{p210}](#) element in this example, which is part of the original text being quoted, and the [mark^{p238}](#) element, which is highlighting a part for comment.

Example

The following example shows the difference between denoting the *importance* of a span of text ([strong^{p211}](#)) as opposed to denoting the *relevance* of a span of text ([mark^{p238}](#)). It is an extract from a textbook, where the extract has had the parts relevant to the exam highlighted. The safety warnings, important though they may be, are apparently not relevant to the exam.

```
<h3>Wormhole Physics Introduction</h3>

<p><mark>A wormhole in normal conditions can be held open for a  
maximum of just under 39 minutes.</mark> Conditions that can increase  
the time include a powerful energy source coupled to one or both of  
the gates connecting the wormhole, and a large gravity well (such as a  
black hole).</p>

<p><mark>Momentum is preserved across the wormhole. Electromagnetic  
radiation can travel in both directions through a wormhole,  
but matter cannot.</mark></p>

<p>When a wormhole is created, a vortex normally forms.  
<strong>Warning: The vortex caused by the wormhole opening will  
annihilate anything in its path.</strong> Vortexes can be avoided when  
using sufficiently advanced dialing technology.</p>

<p><mark>An obstruction in a gate will prevent it from accepting a  
wormhole connection.</mark></p>
```

4.5.24 The **bdi** element

Spec bugs: [27475](#)

Categories^{p113}:

[Flow content^{p115}](#).
[Phrasing content^{p116}](#).
[Palpable content^{p117}](#).

Contexts in which this element can be used^{p113}:

Where [phrasing content^{p116}](#) is expected.

Content model^{p113}:

[Phrasing content^{p116}](#).

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes^{p120}](#)

Also, the [dir^{p125}](#) global attribute has special semantics on this element.

DOM interface^{p113}:

Uses [HTMLElement^{p112}](#).

The [bdi^{p240}](#) element [represents^{p111}](#) a span of text that is to be isolated from its surroundings for the purposes of bidirectional text formatting. [\[BIDI\]^{p1148}](#)

Note *The dir^{p125} global attribute defaults to auto^{p125} on this element (it never inherits from the parent element like with other elements).*

Note This element has rendering requirements involving the bidirectional algorithm^{p132}

Example

This element is especially useful when embedding user-generated content with an unknown directionality.

In this example, usernames are shown along with the number of posts that the user has submitted. If the `bdi`²⁴⁰ element were not used, the username of the Arabic user would end up confusing the text (the bidirectional algorithm would put the colon and the number "3" next to the word "User" rather than next to the word "posts").

```
<ul>
  <li>User <bdi>jcranmer</bdi>: 12 posts.
  <li>User <bdi>hober</bdi>: 5 posts.
  <li>User <bdi>نابليون</bdi>: 3 posts.
</ul>
```

- User jcranmer: 12 posts.
 - User hober: 5 posts.
 - User ایان: 3 posts.

When using the `bdi`^{p240} element, the username acts as expected.

- User **jcranmer**: 12 posts.
 - User **hober**: 5 posts.
 - User **إيان**: 3 posts.

If the `bdi`^{p240} element were to be replaced by a `b`^{p236} element, the username would confuse the bidirectional algorithm and the third bullet would end up saying "User 3:", followed by the Arabic name (right-to-left), followed by "posts" and a period.

4.5.25 The **bdo** element

Categories^{p113}:

Flow content^{p115}

Phrasing content^{p116}

Palpable content^{p117}

Contexts in which this element can be used^{p113}:

Where phrasing content^{p116} is expected.

Content model^{p113}:

Phrasing content^{p116}

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes

Global attributes^{p120}

Also, the `dir`^{p125} global attribute has special semantics on this element.

DOM interface^{p113}.

Uses `HTMLElement` p112

The `bdo`^{p241} element represents^{p111} explicit text directionality formatting control for its children. It allows authors to override the Unicode bidirectional algorithm by explicitly specifying a direction override. [BIDI]^{p1148}

Authors must specify the `dir`^{p125} attribute on this element, with the value `ltr`^{p125} to specify a left-to-right override and with the value `rtl`^{p125} to specify a right-to-left override. The `auto`^{p125} value must not be specified.

Note This element has rendering requirements involving the bidirectional algorithm.^{p132}

4.5.26 The `span` element

Categories^{p113}:

[Flow content](#)^{p115}.
[Phrasing content](#)^{p116}.
[Palpable content](#)^{p117}.

Contexts in which this element can be used^{p113}:

Where [phrasing content](#)^{p116} is expected.

Content model^{p113}:

[Phrasing content](#)^{p116}.

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes](#)^{p120}

DOM interface^{p113}:

```
IDL interface HTMLSpanElement : HTMLElement {};
```

The [span](#)^{p242} element doesn't mean anything on its own, but can be useful when used together with the [global attributes](#)^{p120}, e.g. [class](#)^{p128}, [lang](#)^{p123}, or [dir](#)^{p125}. It [represents](#)^{p111} its children.

Example

In this example, a code fragment is marked up using [span](#)^{p242} elements and [class](#)^{p128} attributes so that its keywords and identifiers can be colour-coded from CSS:

```
<pre><code class="lang-c"><span class="keyword">for</span> (<span class="ident">j</span> = 0;
<span class="ident">j</span> &lt; 256; <span class="ident">j</span>++) {
    <span class="ident">i_t3</span> = (<span class="ident">i_t3</span> & 0xffff) | (<span
class="ident">j</span> &lt;&lt; 17);
    <span class="ident">i_t6</span> = (((((<span class="ident">i_t3</span> >> 3) ^ <span
class="ident">i_t3</span>) >> 1) ^ <span class="ident">i_t3</span>) >> 8) ^ <span
class="ident">i_t3</span>) >> 5) & 0xff;
    <span class="keyword">if</span> (<span class="ident">i_t6</span> == <span
class="ident">i_t1</span>)
        <span class="keyword">break</span>;
}</code></pre>
```

4.5.27 The `br` element

Categories^{p113}:

[Flow content](#)^{p115}.
[Phrasing content](#)^{p116}.

Contexts in which this element can be used^{p113}:

Where [phrasing content](#)^{p116} is expected.

Content model^{p113}:

[Nothing](#)^{p114}.

Tag omission in text/html^{p113}:

No [end tag](#)^{p944}.

Content attributes^{p113}:

[Global attributes](#)^{p120}

DOM interface^{p113}:

```
IDL    interface HTMLBRElement : HTMLElement {  
    // also has obsolete members  
};
```

The br^{p242} element represents^{p111} a line break.

Note While line breaks are usually represented in visual media by physically moving subsequent text to a new line, a style sheet or user agent would be equally justified in causing line breaks to be rendered in a different manner, for instance as green dots, or as extra spacing.

br^{p242} elements must be used only for line breaks that are actually part of the content, as in poems or addresses.

Example

The following example is correct usage of the br^{p242} element:

```
<p>P. Sherman<br>  
42 Wallaby Way<br>  
Sydney</p>
```

br^{p242} elements must not be used for separating thematic groups in a paragraph.

Example

The following examples are non-conforming, as they abuse the br^{p242} element:

```
<p><a ...>34 comments.</a><br>  
<a ...>Add a comment.</a></p>  
  
<p><label>Name: <input name="name"></label><br>  
<label>Address: <input name="address"></label></p>
```

Here are alternatives to the above, which are correct:

```
<p><a ...>34 comments.</a></p>  
<p><a ...>Add a comment.</a></p>  
  
<p><label>Name: <input name="name"></label></p>  
<p><label>Address: <input name="address"></label></p>
```

If a paragraph^{p118} consists of nothing but a single br^{p242} element, it represents a placeholder blank line (e.g. as in a template). Such blank lines must not be used for presentation purposes.

Any content inside br^{p242} elements must not be considered part of the surrounding text.

Note This element has rendering requirements involving the bidirectional algorithm^{p132}.

4.5.28 The **wbr** element

Spec bugs: [27450](#), [27451](#)

Categories^{p113}:

Flow content^{p115}.
Phrasing content^{p116}.

Contexts in which this element can be used^{p113}:

Where phrasing content^{p116} is expected.

Content model^{p113}:

Nothing^{p114}.

Tag omission in text/html^{p113}:

No end tag^{p944}.

Content attributes^{p113}:

Global attributes^{p120}

DOM interface^{p113}:

Uses HTMLElement^{p112}.

The wbr^{p243} element represents^{p111} a line break opportunity.

Example

In the following example, someone is quoted as saying something which, for effect, is written as one long word. However, to ensure that the text can be wrapped in a readable fashion, the individual words in the quote are separated using a wbr^{p243} element.

```
<p>So then he pointed at the tiger and screamed  
"there<wbr>is<wbr>no<wbr>way<wbr>you<wbr>are<wbr>ever<wbr>going<wbr>to<wbr>catch<wbr>me"!</p>
```

Example

Here, especially long lines of code in a program listing have suggested wrapping points given using wbr^{p243} elements.

```
<pre>...  
Heading heading = Helm.HeadingFactory(HeadingCoordinates[1], <wbr>HeadingCoordinates[2],  
<wbr>HeadingCoordinates[3], <wbr>HeadingCoordinates[4]);  
Course course = Helm.CourseFactory(Heading, <wbr>Maps.MapFactoryFromHeading(heading),  
<wbr>Speeds.GetMaximumSpeed().ConvertToWarp());  
...</pre>
```

Any content inside wbr^{p243} elements must not be considered part of the surrounding text.

Note *This element has rendering requirements involving the bidirectional algorithm*^{p132}.

4.5.29 Usage summary

This section is non-normative.

Element	Purpose	Example
<u>a</u> ^{p208}	Hyperlinks	Visit my drinks page.
<u>em</u> ^{p210}	Stress emphasis	I must say I adore lemonade.
<u>strong</u> ^{p211}	Importance	This tea is very hot.
<u>small</u> ^{p212}	Side comments	These grapes are made into wine. <small>Alcohol is addictive.</small>
<u>s</u> ^{p214}	Inaccurate text	Price: <s>£4.50</s> £2.00!
<u>cite</u> ^{p214}	Titles of works	The case <cite>Hugo v. Danielle</cite> is relevant here.
<u>q</u> ^{p215}	Quotations	The judge said <q>You can drink water from the fish tank</q> but advised against it.
<u>dfn</u> ^{p217}	Defining instance	The term <dfn>organic food</dfn> refers to food produced without synthetic chemicals.
<u>abbr</u> ^{p218}	Abbreviations	Organic food in Ireland is certified by the <abbr title="Irish Organic Farmers and Growers Association">IOFGA</abbr>.
<u>ruby</u> ^{p219} , <u>rt</u> ^{p225} , <u>rp</u> ^{p225}	Ruby annotations	<ruby> OJ <rp>(<rt>Orange Juice</rt></rp>)</ruby>
<u>data</u> ^{p226}	Machine-readable equivalent	Available starting today! <data value="UPC:022014640201">North Coast Organic Apple Cider</data>
<u>time</u> ^{p227}	Machine-readable equivalent of date- or time-related data	Available starting on <time datetime="2011-11-12">November 12th</time>!
<u>code</u> ^{p231}	Computer code	The <code>fruitdb</code> program can be used for tracking fruit production.
<u>var</u> ^{p232}	Variables	If there are <var>n</var> fruit in the bowl, at least <var>n</var>+2 will be ripe.
<u>samp</u> ^{p233}	Computer output	The computer said <samp>Unknown error -3</samp>.
<u>kbd</u> ^{p234}	User input	Hit <kbd>F1</kbd> to continue.

Element	Purpose	Example
<code>sub^{b235}</code>	Subscripts	Water is H ₂ .
<code>sup^{b235}</code>	Superscripts	The Hydrogen in heavy water is usually ² H.
<code>i^{p235}</code>	Alternative voice	Lemonade consists primarily of <i>Citrus limon</i> .
<code>b^{p236}</code>	Keywords	Take a lemon and squeeze it with a juicer .
<code>u^{p237}</code>	Annotations	The mixture of apple juice and <u>elderflower</u> juice is very pleasant.
<code>mark^{p238}</code>	Highlight	Elderflower cordial, with one <mark>part</mark> cordial to ten <mark>part</mark> s water, stands a <mark>part</mark> from the rest.
<code>bdi^{b240}</code>	Text directionality isolation	The recommended restaurant is <bdi >my="" (at="" bdi>.<="" beach)<="" café="" juice="" lang="" td="" the=""></bdi>
<code>bdo^{b241}</code>	Text directionality formatting	The proposal is to write English, but in reverse order. "Juice" would become " <bdo >juice<="" bdo>"<="" dir="rtl" td=""></bdo>
<code>span^{p242}</code>	Other	In French we call it sirop="" de="" lang="fr" span>.<="" sureau<="" td="">
<code>br^{p242}</code>	Line break	Simply Orange Juice Company Apopka, FL 32703 U.S.A.
<code>wbr^{b243}</code>	Line breaking opportunity	www.simply <code>wbr</code> orange <code>wbr</code> juice.com

4.6 Links

4.6.1 Introduction

Links are a conceptual construct, created by `ap208`, `areap390`, and `linkp141` elements, that represent^{p111} a connection between two resources, one of which is the current Document^{b102}. There are two kinds of links in HTML:

Links to external resources

These are links to resources that are to be used to augment the current document, generally automatically processed by the user agent.

Hyperlinks

These are links to other resources that are generally exposed to the user by the user agent so that the user can cause the user agent to navigate^{p791} to those resources, e.g. to visit them in a browser or download them.

For `linkp141` elements with an `hrefp142` attribute and a `relp142` attribute, links must be created for the keywords of the `relp142` attribute, as defined for those keywords in the link types^{p250} section.

Similarly, for `ap208` and `areap390` elements with an `hrefp245` attribute and a `relp246` attribute, links must be created for the keywords of the `relp246` attribute as defined for those keywords in the link types^{p250} section. Unlike `linkp141` elements, however, `ap208` and `areap390` element with an `hrefp245` attribute that either do not have a `relp246` attribute, or whose `relp246` attribute has no keywords that are defined as specifying hyperlinks^{p245}, must also create a hyperlink^{p245}. This implied hyperlink has no special meaning (it has no link type^{p250}) beyond linking the element's node document to the resource given by the element's `hrefp245` attribute.

A hyperlink^{p245} can have one or more **hyperlink annotations** that modify the processing semantics of that hyperlink.

4.6.2 Links created by `ap208` and `areap390` elements

The `href` attribute on `ap208` and `areap390` elements must have a value that is a valid URL potentially surrounded by spaces^{b82}.

Note *The `hrefp245` attribute on `ap208` and `areap390` elements is not required; when those elements do not have `hrefp245` attributes they do not create hyperlinks.*

The `target` attribute, if present, must be a valid browsing context name or keyword^{p766}. It gives the name of the browsing context^{p762} that will be used. User agents use this name when following hyperlinks^{p246}.

When an `ap208` or `areap390` element's activation behaviour^{p725} is invoked, the user agent may allow the user to indicate a preference regarding whether the hyperlink is to be used for navigation^{p791} or whether the resource it specifies is to be downloaded.

In the absence of a user preference, the default should be navigation if the element has no [download](#)^{p246} attribute, and should be to download the specified resource if it does.

Whether determined by the user's preferences or via the presence or absence of the attribute, if the decision is to use the hyperlink for [navigation](#)^{p791} then the user agent must [follow the hyperlink](#)^{p246}, and if the decision is to use the hyperlink to download a resource, the user agent must [download the hyperlink](#)^{p247}. These terms are defined in subsequent sections below.

The [download](#) attribute, if present, indicates that the author intends the hyperlink to be used for downloading a resource. The attribute may have a value; the value, if any, specifies the default file name that the author recommends for use in labeling the resource in a local file system. There are no restrictions on allowed values, but authors are cautioned that most file systems have limitations with regard to what punctuation is supported in file names, and user agents are likely to adjust file names accordingly.

The [ping](#) attribute, if present, gives the URLs of the resources that are interested in being notified if the user follows the hyperlink. The value must be a [set of space-separated tokens](#)^{p80}, each of which must be a [valid non-empty URL](#)^{p82}. The value is used by the user agent for [hyperlink auditing](#)^{p249}.

The [rel](#) attribute on [a](#)^{p208} and [area](#)^{p390} elements controls what kinds of links the elements create. The attribute's value must be a [set of space-separated tokens](#)^{p80}. The [allowed keywords and their meanings](#)^{p250} are defined below.

The [rel](#)^{p246} attribute has no default value. If the attribute is omitted or if none of the values in the attribute are recognised by the user agent, then the document has no particular relationship with the destination resource other than there being a hyperlink between the two.

The [hreflang](#) attribute on [a](#)^{p208} and [area](#)^{p390} elements that create [hyperlinks](#)^{p245}, if present, gives the language of the linked resource. It is purely advisory. The value must be a valid BCP 47 language tag. [\[BCP47\]^{p1148}](#) User agents must not consider this attribute authoritative — upon fetching the resource, user agents must use only language information associated with the resource to determine its language, not metadata included in the link to the resource.

The [type](#) attribute, if present, gives the [MIME type](#)^{p42} of the linked resource. It is purely advisory. The value must be a [valid MIME type](#)^{p42}. User agents must not consider the [type](#)^{p246} attribute authoritative — upon fetching the resource, user agents must not use metadata included in the link to the resource to determine its type.

4.6.3 Following hyperlinks

When a user **follows a hyperlink** created by an element *subject*, the user agent must run the following steps:

1. Let *replace* be false.
2. Let *source* be the [browsing context](#)^{p762} that contains the [Document](#)^{p102} object with which *subject* in question is associated.
3. If the user indicated a specific [browsing context](#)^{p762} when following the hyperlink, or if the user agent is configured to follow hyperlinks by navigating a particular browsing context, then let *target* be that [browsing context](#)^{p762}. If this is a new [top-level browsing context](#)^{p763} (e.g. when the user followed the hyperlink using "Open in New Tab"), then *source* must be set as the new [browsing context](#)^{p762}'s [one permitted sandboxed navigator](#)^{p780}.

Otherwise, if *subject* is an [a](#)^{p208} or [area](#)^{p390} element that has a [target](#)^{p245} attribute, then let *target* be the [browsing context](#)^{p762} that is chosen by applying [the rules for choosing a browsing context given a browsing context name](#)^{p767}, using the value of the [target](#)^{p245} attribute as the browsing context name. If these rules result in the creation of a new [browsing context](#)^{p762}, set *replace* to true.

Otherwise, if the hyperlink is a [sidebar hyperlink](#)^{p256}, the user agent implements a feature that can be considered a [secondary browsing context](#)^{p764}, and the user agent intends to use this feature in this instance, let *target* be such a [secondary browsing context](#)^{p764}.

Otherwise, if *target* is an [a](#)^{p208} or [area](#)^{p390} element with no [target](#)^{p245} attribute, but the [Document](#)^{p102} contains a [base](#)^{p140} element with a [target](#)^{p140} attribute, then let *target* be the [browsing context](#)^{p762} that is chosen by applying [the rules for choosing a browsing context given a browsing context name](#)^{p767}, using the value of the [target](#)^{p140} attribute of the first such [base](#)^{p140} element as the browsing context name. If these rules result in the creation of a new [browsing context](#)^{p762}, set *replace* to true.

Otherwise, let *target* be the [browsing context](#)^{p762} that *subject* itself is in.

4. [Resolve](#)^{p82} the [URL](#)^{p48} given by the [href](#)^{p245} attribute of that element, relative to that element.
5. If that is successful, let *URL* be the [resulting absolute URL](#)^{p83}.

Otherwise, if [resolving^{p82}](#) the [URL^{p48}](#) failed, the user agent may report the error to the user in a user-agent-specific manner, may [queue a task^{p835}](#) to [navigate^{p791}](#) the [target browsing context^{p762}](#) to an error page to report the error, or may ignore the error and do nothing. In any case, the user agent must then abort these steps.

6. In the case of server-side image maps, append the [hyperlink suffix^{p209}](#) to *URL*.
7. [Queue a task^{p835}](#) to [navigate^{p791}](#) the [target browsing context^{p762}](#) to *URL*. If *replace* is true, the navigation must be performed with [replacement enabled^{p802}](#). The [source browsing context^{p791}](#) must be *source*.

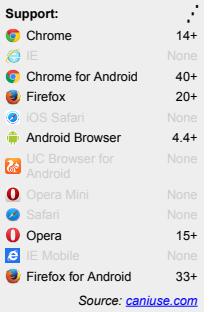

The [task source^{p835}](#) for the tasks mentioned above is the [DOM manipulation task source^{p838}](#).

4.6.4 Downloading resources

In some cases, resources are intended for later use rather than immediate viewing. To indicate that a resource is intended to be used later, rather than immediately used, the [download^{p246}](#) attribute can be specified on the [a^{p208}](#) or [area^{p390}](#) element that creates a link to that resource.

The attribute can furthermore be given a value, to specify the file name that user agents are to use when storing the resource in a cache. This value can be overridden by the [Content-Disposition^{p49}](#) HTTP header's filename parameters. [RFC6266]^{p1153}

In cross-origin situations, the [download^{p246}](#) attribute has to be combined with the [Content-Disposition^{p49}](#) HTTP header, specifying the [attachment](#) disposition type, to avoid the user being warned of possibly nefarious activity. (This is to protect users from being made to download sensitive personal or confidential information without their full understanding.)

When a user **downloads a hyperlink** created by an element, the user agent must run the following steps:

1. [Resolve^{p82}](#) the [URL^{p48}](#) given by the [href^{p245}](#) attribute of that element, relative to that element.
2. If [resolving^{p82}](#) the [URL^{p48}](#) fails, the user agent may report the error to the user in a user-agent-specific manner, may [navigate^{p791}](#) to an error page to report the error, or may ignore the error and do nothing. In either case, the user agent must abort these steps.
3. Otherwise, let *URL* be the resulting [absolute URL^{p48}](#).
4. In the case of server-side image maps, append the [hyperlink suffix^{p209}](#) to *URL*.
5. Return to whatever algorithm invoked these steps and continue these steps [in parallel^{p41}](#).
6. [Fetch^{p84}](#) *URL* and handle the resulting resource [as a download^{p247}](#).

When a user agent is to handle a resource obtained from a [fetch^{p84}](#) algorithm **as a download**, it should provide the user with a way to save the resource for later use, if a resource is successfully obtained; or otherwise should report any problems downloading the file to the user.

If the user agent needs a file name for a resource being handled [as a download^{p247}](#), it should select one using the following algorithm.

⚠️Warning! *This algorithm is intended to mitigate security dangers involved in downloading files from untrusted sites, and user agents are strongly urged to follow it.*

1. Let *filename* be the void value.
2. If the resource has a [Content-Disposition^{p49}](#) header, that header specifies the [attachment](#) disposition type, and the header includes file name information, then let *filename* have the value specified by the header, and jump to the step labeled *sanitize* below. [RFC6266]^{p1153}
3. Let *interface origin* be the [origin^{p776}](#) of the [Document^{p102}](#) in which the [download^{p247}](#) or [navigate^{p791}](#) action resulting in the download was initiated, if any.
4. Let *resource origin* be the [origin^{p776}](#) of the URL of the resource being downloaded, unless that URL's [scheme^{p48}](#) component is [data](#), in which case let *resource origin* be the same as the *interface origin*, if any.
5. If there is no *interface origin*, then let *trusted operation* be true. Otherwise, let *trusted operation* be true if *resource origin* is the [same origin^{p778}](#) as *interface origin*, and false otherwise.

6. If *trusted operation* is true and the resource has a [Content-Disposition^{p49}](#) header and that header includes file name information, then let *filename* have the value specified by the header, and jump to the step labeled *sanitize* below. [[RFC6266](#)^{p1153}]
7. If the download was not initiated from a [hyperlink^{p245}](#) created by an [a^{p208}](#) or [area^{p390}](#) element, or if the element of the [hyperlink^{p245}](#) from which it was initiated did not have a [download^{p246}](#) attribute when the download was initiated, or if there was such an attribute but its value when the download was initiated was the empty string, then jump to the step labeled *no proposed file name*.
8. Let *proposed filename* have the value of the [download^{p246}](#) attribute of the element of the [hyperlink^{p245}](#) that initiated the download at the time the download was initiated.
9. If *trusted operation* is true, let *filename* have the value of *proposed filename*, and jump to the step labeled *sanitize* below.
10. If the resource has a [Content-Disposition^{p49}](#) header and that header specifies the `attachment` disposition type, let *filename* have the value of *proposed filename*, and jump to the step labeled *sanitize* below. [[RFC6266](#)^{p1153}]
11. *No proposed file name*: If *trusted operation* is true, or if the user indicated a preference for having the resource in question downloaded, let *filename* have a value derived from the [URL^{p48}](#) of the resource in a user-agent-defined manner, and jump to the step labeled *sanitize* below.
12. Act in a user-agent-defined manner to safeguard the user from a potentially hostile cross-origin download. If the download is not to be aborted, then let *filename* be set to the user's preferred file name or to a file name selected by the user agent, and jump to the step labeled *sanitize* below.

If the algorithm reaches this step, then a download was begun from a different origin than the resource being downloaded, and the origin did not mark the file as suitable for downloading, and the download was not initiated by the user. This could be because a [download^{p246}](#) attribute was used to trigger the download, or because the resource in question is not of a type that the user agent supports.

This could be dangerous, because, for instance, a hostile server could be trying to get a user to unknowingly download private information and then re-upload it to the hostile server, by tricking the user into thinking the data is from the hostile server.

Thus, it is in the user's interests that the user be somehow notified that the resource in question comes from quite a different source, and to prevent confusion, any suggested file name from the potentially hostile interface origin should be ignored.

13. *Sanitize*: Optionally, allow the user to influence *filename*. For example, a user agent could prompt the user for a file name, potentially providing the value of *filename* as determined above as a default value.
 14. Adjust *filename* to be suitable for the local file system.
- Example** For example, this could involve removing characters that are not legal in file names, or trimming leading and trailing whitespace.
15. If the platform conventions do not in any way use [extensions^{p249}](#) to determine the types of file on the file system, then return *filename* as the file name and abort these steps.
 16. Let *claimed type* be the type given by the resource's [Content-Type metadata^{p86}](#), if any is known. Let *named type* be the type given by *filename*'s [extension^{p249}](#), if any is known. For the purposes of this step, a *type* is a mapping of a [MIME type^{p42}](#) to an [extension^{p249}](#).
 17. If *named type* is consistent with the user's preferences (e.g. because the value of *filename* was determined by prompting the user), then return *filename* as the file name and abort these steps.
 18. If *claimed type* and *named type* are the same type (i.e. the type given by the resource's [Content-Type metadata^{p86}](#) is consistent with the type given by *filename*'s [extension^{p249}](#)), then return *filename* as the file name and abort these steps.
 19. If the *claimed type* is known, then alter *filename* to add an [extension^{p249}](#) corresponding to *claimed type*.

Otherwise, if *named type* is known to be potentially dangerous (e.g. it will be treated by the platform conventions as a native executable, shell script, HTML application, or executable-macro-capable document) then optionally alter *filename* to add a known-safe [extension^{p249}](#) (e.g. ".txt").

Note *This last step would make it impossible to download executables, which might not be desirable. As always, implementors are forced to balance security and usability in this matter.*

20. Return *filename* as the file name.

For the purposes of this algorithm, a file **extension** consists of any part of the file name that platform conventions dictate will be used for identifying the type of the file. For example, many operating systems use the part of the file name following the last dot (".") in the file name to determine the type of the file, and from that the manner in which the file is to be opened or executed.

User agents should ignore any directory or path information provided by the resource itself, its [URL^{p48}](#), and any [download^{p246}](#) attribute, in deciding where to store the resulting file in the user's file system.

Spec bugs: [24137](#)

4.6.4.1 Hyperlink auditing

If a [hyperlink^{p245}](#) created by an [a^{p208}](#) or [area^{p390}](#) element has a [ping^{p246}](#) attribute, and the user follows the hyperlink, and the value of the element's [href^{p245}](#) attribute can be [resolved^{p82}](#), relative to the element, without failure, then the user agent must take the [ping^{p246}](#) attribute's value, [split that string on spaces^{p80}](#), [resolve^{p82}](#) each resulting token relative to the element, and then each [resulting absolute URL^{p83}](#) [ping URL](#) should be [fetched^{p84}](#) from the [origin^{p776}](#) of the [Document^{p102}](#) containing the [hyperlink^{p245}](#) (as described below). (Tokens that fail to resolve are ignored.) This may be done in parallel with the primary request, and is independent of the result of that request.

User agents should allow the user to adjust this behaviour, for example in conjunction with a setting that disables the sending of HTTP [Referer^{p49}](#) (sic) headers. Based on the user's preferences, UAs may either [ignore^{p42}](#) the [ping^{p246}](#) attribute altogether, or selectively ignore URLs in the list (e.g. ignoring any third-party URLs).

For each [ping URL](#) that is an HTTP URL, the request must be performed using the POST method, with an entity body with the [MIME type^{p42}](#) [text/ping^{p1121}](#) consisting of the four-character string "PING". All relevant cookie and HTTP authentication headers must be included in the request.

Which other headers are required depends on the URLs involved, as follows. For the purposes of these requirements, [target URL](#) is the [resulting absolute URL^{p83}](#) obtained from [resolving^{p82}](#) the value of the element's [href^{p245}](#) attribute.

↪ If both the [address](#) of the [Document^{p102}](#) object containing the hyperlink being audited and [ping URL](#) have the [same origin^{p778}](#)

The request must include a [Ping-From^{p1123}](#) HTTP header with, as its value, the [address](#) of the document containing the hyperlink, and a [Ping-To^{p1123}](#) HTTP header with, as its value, the [target URL](#). The request must not include a [Referer^{p49}](#) (sic) HTTP header.

↪ Otherwise, if the origins are different, but the document containing the hyperlink being audited was not retrieved over an encrypted connection

The request must include a [Referer^{p49}](#) (sic) HTTP header with, as its value, the [address](#) of the document containing the hyperlink, a [Ping-From^{p1123}](#) HTTP header with the same value, and a [Ping-To^{p1123}](#) HTTP header with, as its value, [target URL](#).

↪ Otherwise, the origins are different and the document containing the hyperlink being audited was retrieved over an encrypted connection

The request must include a [Ping-To^{p1123}](#) HTTP header with, as its value, [target URL](#). The request must neither include a [Referer^{p49}](#) (sic) HTTP header nor include a [Ping-From^{p1123}](#) HTTP header.

Note To save bandwidth, implementors might also wish to consider omitting optional headers such as [Accept^{p48}](#) from these requests.

User agents must, unless otherwise specified by the user, honor the HTTP headers (including, in particular, redirects and HTTP cookie headers), but must ignore any entity bodies returned in the responses. User agents may close the connection prematurely once they start receiving an entity body. [\[COOKIES\]^{p1148}](#)

When the [ping^{p246}](#) attribute is present, user agents should clearly indicate to the user that following the hyperlink will also cause secondary requests to be sent in the background, possibly including listing the actual target URLs.

Example For example, a visual user agent could include the hostnames of the target ping URLs along with the hyperlink's actual URL in a status bar or tooltip.

Note The [ping^{p246}](#) attribute is redundant with pre-existing technologies like HTTP redirects and JavaScript in allowing Web pages to track which off-site links are most popular or allowing advertisers to track click-through rates.

However, the [ping^{p246}](#) attribute provides these advantages to the user over those alternatives:

- It allows the user to see the final target URL unobscured.
- It allows the UA to inform the user about the out-of-band notifications.
- It allows the user to disable the notifications without losing the underlying link functionality.

- It allows the UA to optimise the use of available network bandwidth so that the target page loads faster.

Thus, while it is possible to track users without this feature, authors are encouraged to use the [ping^{p246}](#) attribute so that the user agent can make the user experience more transparent.

Spec bugs: [22175](#)

4.6.5 Link types

The following table summarizes the link types that are defined by this specification. This table is non-normative; the actual definitions for the link types are given in the next few sections.

In this section, the term *referenced document* refers to the resource identified by the element representing the link, and the term *current document* refers to the resource within which the element representing the link finds itself.

To determine which link types apply to a [link^{p141}](#), [a^{p208}](#), or [area^{p390}](#) element, the element's `rel` attribute must be [split on spaces^{p80}](#). The resulting tokens are the link types that apply to that element.

Except where otherwise specified, a keyword must not be specified more than once per [rel^{p246}](#) attribute.

Link types are always [ASCII case-insensitive^{p58}](#), and must be compared as such.

Example Thus, `rel="next"` is the same as `rel="NEXT"`.

Link type	Effect on...		Brief description
	link^{p141}	a^{p208} and area^{p390}	
alternate^{p250}	Hyperlink^{p245}	Hyperlink^{p245}	Gives alternate representations of the current document.
author^{p251}	Hyperlink^{p245}	Hyperlink^{p245}	Gives a link to the author of the current document or article.
bookmark^{p252}	<i>not allowed</i>	Hyperlink^{p245}	Gives the permalink for the nearest ancestor section.
external^{p252}	<i>not allowed</i>	Annotation^{p245}	Indicates that the referenced document is not part of the same site as the current document.
help^{p252}	Hyperlink^{p245}	Hyperlink^{p245}	Provides a link to context-sensitive help.
icon^{p253}	External Resource^{p245}	<i>not allowed</i>	Imports an icon to represent the current document.
license^{p254}	Hyperlink^{p245}	Hyperlink^{p245}	Indicates that the main content of the current document is covered by the copyright license described by the referenced document.
next^{p259}	Hyperlink^{p245}	Hyperlink^{p245}	Indicates that the current document is a part of a series, and that the next document in the series is the referenced document.
nofollow^{p255}	<i>not allowed</i>	Annotation^{p245}	Indicates that the current document's original author or publisher does not endorse the referenced document.
noreferrer^{p255}	<i>not allowed</i>	Annotation^{p245}	Requires that the user agent not send an HTTP Referer^{p49} (sic) header if the user follows the hyperlink.
pingback^{p255}	External Resource^{p245}	<i>not allowed</i>	Gives the address of the pingback server that handles pingbacks to the current document.
prefetch^{p255}	External Resource^{p245}	External Resource^{p245}	Specifies that the target resource should be preemptively cached.
prey^{p259}	Hyperlink^{p245}	Hyperlink^{p245}	Indicates that the current document is a part of a series, and that the previous document in the series is the referenced document.
search^{p256}	Hyperlink^{p245}	Hyperlink^{p245}	Gives a link to a resource that can be used to search through the current document and its related pages.
sidebar^{p256}	Hyperlink^{p245}	Hyperlink^{p245}	Specifies that the referenced document, if retrieved, is intended to be shown in the browser's sidebar (if it has one).
stylesheet^{p256}	External Resource^{p245}	<i>not allowed</i>	Imports a stylesheet.
tag^{p257}	<i>not allowed</i>	Hyperlink^{p245}	Gives a tag (identified by the given address) that applies to the current document.

Some of the types described below list synonyms for these values. These are to be handled as specified by user agents, but must not be used in documents.

4.6.5.1 Link type "[alternate](#)"

The [alternate^{p250}](#) keyword may be used with [link^{p141}](#), [a^{p208}](#), and [area^{p390}](#) elements.

The meaning of this keyword depends on the values of the other attributes.

↪ If the element is a [link^{p141}](#) element and the [rel^{p142}](#) attribute also contains the keyword [stylesheet^{p256}](#)

The [alternate^{p250}](#) keyword modifies the meaning of the [stylesheet^{p256}](#) keyword in the way described for that keyword. The [alternate^{p250}](#) keyword does not create a link of its own.

↪ If the [alternate^{p250}](#) keyword is used with the [type^{p246}](#) attribute set to the value `application/rss+xml` or the value `application/atom+xml`

The keyword creates a [hyperlink^{p245}](#) referencing a syndication feed (though not necessarily syndicating exactly the same content as the current page).

The first [link^{p141}](#), [a^{p208}](#), or [area^{p390}](#) element in the document (in [tree order^{p42}](#)) with the [alternate^{p250}](#) keyword used with the [type^{p246}](#) attribute set to the value `application/rss+xml` or the value `application/atom+xml` must be treated as the default syndication feed for the purposes of feed autodiscovery.

Example The following [link^{p141}](#) element gives the syndication feed for the current page:

```
<link rel="alternate" type="application/atom+xml" href="data.xml">
```

The following extract offers various different syndication feeds:

```
<p>You can access the planets database using Atom feeds:</p>
<ul>
  <li><a href="recently-visited-planets.xml" rel="alternate" type="application/atom+xml">Recently Visited Planets</a></li>
  <li><a href="known-bad-planets.xml" rel="alternate" type="application/atom+xml">Known Bad Planets</a></li>
  <li><a href="unexplored-planets.xml" rel="alternate" type="application/atom+xml">Unexplored Planets</a></li>
</ul>
```

↪ Otherwise

The keyword creates a [hyperlink^{p245}](#) referencing an alternate representation of the current document.

The nature of the referenced document is given by the [hreflang^{p246}](#), and [type^{p246}](#) attributes.

If the [alternate^{p250}](#) keyword is used with the [hreflang^{p246}](#) attribute, and that attribute's value differs from the [root element^{p42}](#)'s [language^{p123}](#), it indicates that the referenced document is a translation.

If the [alternate^{p250}](#) keyword is used with the [type^{p246}](#) attribute, it indicates that the referenced document is a reformulation of the current document in the specified format.

The [hreflang^{p246}](#) and [type^{p246}](#) attributes can be combined when specified with the [alternate^{p250}](#) keyword.

Example For example, the following link is a French translation that uses the PDF format:

```
<link rel=alternate type=application/pdf hreflang=fr href=manual-fr>
```

This relationship is transitive — that is, if a document links to two other documents with the link type "[alternate^{p250}](#)", then, in addition to implying that those documents are alternative representations of the first document, it is also implying that those two documents are alternative representations of each other.

4.6.5.2 Link type "author"

The [author^{p251}](#) keyword may be used with [link^{p141}](#), [a^{p208}](#), and [area^{p390}](#) elements. This keyword creates a [hyperlink^{p245}](#).

For [a^{p208}](#) and [area^{p390}](#) elements, the [author^{p251}](#) keyword indicates that the referenced document provides further information about the author of the nearest [article^{p159}](#) element ancestor of the element defining the hyperlink, if there is one, or of the page as a whole, otherwise.

For [link](#)^{p141} elements, the [author](#)^{p251} keyword indicates that the referenced document provides further information about the author for the page as a whole.

Note *The "referenced document" can be, and often is, a [mailto:](#) URL giving the e-mail address of the author. [MAILTO]^{p1151}*

Synonyms: For historical reasons, user agents must also treat [link](#)^{p141}, [a](#)^{p208}, and [area](#)^{p390} elements that have a `rev` attribute with the value "made" as having the [author](#)^{p251} keyword specified as a link relationship.

4.6.5.3 Link type "bookmark"

Spec bugs: [23373](#)

The [bookmark](#)^{p252} keyword may be used with [a](#)^{p208} and [area](#)^{p390} elements. This keyword creates a [hyperlink](#)^{p245}.

The [bookmark](#)^{p252} keyword gives a permalink for the nearest ancestor [article](#)^{p159} element of the linking element in question, or of [the section the linking element is most closely associated with](#)^{p180}, if there are no ancestor [article](#)^{p159} elements.

Example

The following snippet has three permalinks. A user agent could determine which permalink applies to which part of the spec by looking at where the permalinks are given.

```
...
<body>
  <h1>Example of permalinks</h1>
  <div id="a">
    <h2>First example</h2>
    <p><a href="a.html" rel="bookmark">This permalink applies to
      only the content from the first H2 to the second H2</a>. The DIV isn't
      exactly that section, but it roughly corresponds to it.</p>
  </div>
  <h2>Second example</h2>
  <article id="b">
    <p><a href="b.html" rel="bookmark">This permalink applies to
      the outer ARTICLE element</a> (which could be, e.g., a blog post).</p>
    <article id="c">
      <p><a href="c.html" rel="bookmark">This permalink applies to
        the inner ARTICLE element</a> (which could be, e.g., a blog comment).</p>
    </article>
  </article>
</body>
...
```

4.6.5.4 Link type "external"

The [external](#)^{p252} keyword may be used with [a](#)^{p208} and [area](#)^{p390} elements. This keyword does not create a [hyperlink](#)^{p245}, but [annotates](#)^{p245} any other hyperlinks created by the element (the implied hyperlink, if no other keywords create one).

The [external](#)^{p252} keyword indicates that the link is leading to a document that is not part of the site that the current document forms a part of.

4.6.5.5 Link type "help"

The [help](#)^{p252} keyword may be used with [link](#)^{p141}, [a](#)^{p208}, and [area](#)^{p390} elements. This keyword creates a [hyperlink](#)^{p245}.

For [a](#)^{p208} and [area](#)^{p390} elements, the [help](#)^{p252} keyword indicates that the referenced document provides further help information for the parent of the element defining the hyperlink, and its children.

Example

In the following example, the form control has associated context-sensitive help. The user agent could use this information, for example, displaying the referenced document if the user presses the "Help" or "F1" key.

```
<p><label> Topic: <input name=topic> <a href="help/topic.html" rel="help">(Help)</a></label></p>
```

For [link^{p141}](#) elements, the [help^{p252}](#) keyword indicates that the referenced document provides help for the page as a whole.

For [a^{p208}](#) and [area^{p390}](#) elements, on some browsers, the [help^{p252}](#) keyword causes the link to use a different cursor.

4.6.5.6 Link type "icon"

The [icon^{p253}](#) keyword may be used with [link^{p141}](#) elements. This keyword creates an [external resource link^{p245}](#).

The specified resource is an icon representing the page or site, and should be used by the user agent when representing the page interface.

Icons could be auditory icons, visual icons, or other kinds of icons. If multiple icons are provided, the user agent must select the most appropriate icon according to the [type^{p144}](#), [media^{p143}](#), and [sizes^{p253}](#) attributes. If there are multiple equally appropriate icons, user agents must select one declared in [tree order^{p42}](#) at the time that the user agent collected the list of icons. If the user agent tries to use an icon but that icon is determined, upon closer examination, to in fact be inappropriate (e.g. because it uses an unsupported format), then the user agent must try the next-most-appropriate icon as determined by the attributes.

Support:	
Chrome	4+
IE	11+
Chrome for Android	40+
Firefox	2+
iOS Safari	None
Android Browser	2.1+
UC Browser for Android	9.9+
Opera Mini	None
Safari	3.1+
Opera	9+
IE Mobile	None
Foxit for Android	33+

Source: caniuse.com

Note User agents are not required to update icons when the list of icons changes, but are encouraged to do so.

There is no default type for resources given by the [icon^{p253}](#) keyword. However, for the purposes of [determining the type of the resource^{p144}](#), user agents must expect the resource to be an image.

The [sizes](#) attribute gives the sizes of icons for visual media. Its value, if present, is merely advisory. User agents may use the value to decide which icon(s) to use if multiple icons are available.

If specified, the attribute must have a value that is an [unordered set of unique space-separated tokens^{p80}](#) which are [ASCII case-insensitive^{p58}](#). Each value must be either an [ASCII case-insensitive^{p58}](#) match for the string "[any^{p253}](#)", or a value that consists of two [valid non-negative integers^{p61}](#) that do not have a leading U+0030 DIGIT ZERO (0) character and that are separated by a single U+0078 LATIN SMALL LETTER X or U+0058 LATIN CAPITAL LETTER X character.

The keywords represent icon sizes in raw pixels (as opposed to CSS pixels).

Note An icon that is 50 CSS pixels wide intended for displays with a device pixel density of two device pixels per CSS pixel (2x, 192dpi) would have a width of 100 raw pixels. This feature does not support indicating that a different resource is to be used for small high-resolution icons vs large low-resolution icons (e.g. 50×50 2x vs 100×100 1x).

To parse and process the attribute's value, the user agent must first [split the attribute's value on spaces^{p80}](#), and must then parse each resulting keyword to determine what it represents.

The [any](#) keyword represents that the resource contains a scalable icon, e.g. as provided by an SVG image.

Other keywords must be further parsed as follows to determine what they represent:

- If the keyword doesn't contain exactly one U+0078 LATIN SMALL LETTER X or U+0058 LATIN CAPITAL LETTER X character, then this keyword doesn't represent anything. Abort these steps for that keyword.
- Let *width string* be the string before the "x" or "X".
- Let *height string* be the string after the "x" or "X".
- If either *width string* or *height string* start with a U+0030 DIGIT ZERO (0) character or contain any characters other than [ASCII digits^{p58}](#), then this keyword doesn't represent anything. Abort these steps for that keyword.
- Apply the [rules for parsing non-negative integers^{p61}](#) to *width string* to obtain *width*.
- Apply the [rules for parsing non-negative integers^{p61}](#) to *height string* to obtain *height*.

- The keyword represents that the resource contains a bitmap icon with a width of *width* device pixels and a height of *height* device pixels.

The keywords specified on the `sizes`^{p253} attribute must not represent icon sizes that are not actually available in the linked resource.

In the absence of a `link`^{p141} with the `icon`^{p253} keyword, for `Document`^{p102}'s obtained over HTTP or HTTPS, user agents may instead attempt to `fetch`^{p84} and use an icon with the `absolute URL`^{p48} obtained by resolving the `URL`^{p48} "/favicon.ico" against `the document's address`, as if the page had declared that icon using the `icon`^{p253} keyword.

Example

The following snippet shows the top part of an application with several icons.

```
<!DOCTYPE HTML>
<html>
<head>
<title>lsForums - Inbox</title>
<link rel=icon href=favicon.png sizes="16x16" type="image/png">
<link rel=icon href=windows.ico sizes="32x32 48x48" type="image/vnd.microsoft.icon">
<link rel=icon href=mac.icns sizes="128x128 512x512 8192x8192 32768x32768">
<link rel=icon href=iphone.png sizes="57x57" type="image/png">
<link rel=icon href=gnome.svg sizes="any" type="image/svg+xml">
<link rel=stylesheet href=lsforums.css>
<script src=lsforums.js></script>
<meta name=application-name content="lsForums">
</head>
<body>
...

```

For historical reasons, the `icon`^{p253} keyword may be preceded by the keyword "shortcut". If the "shortcut" keyword is present, the `rel`^{p246} attribute's entire value must be an `ASCII case-insensitive`^{p58} match for the string "shortcut icon" (with a single U+0020 SPACE character between the tokens and no other `space characters`^{p58}).

4.6.5.7 Link type "license"

The `license`^{p254} keyword may be used with `link`^{p141}, `a`^{p208}, and `area`^{p390} elements. This keyword creates a `hyperlink`^{p245}.

The `license`^{p254} keyword indicates that the referenced document provides the copyright license terms under which the main content of the current document is provided.

This specification does not specify how to distinguish between the main content of a document and content that is not deemed to be part of that main content. The distinction should be made clear to the user.

Example

Consider a photo sharing site. A page on that site might describe and show a photograph, and the page might be marked up as follows:

```
<!DOCTYPE HTML>
<html>
<head>
<title>Exampl Pictures: Kissat</title>
<link rel="stylesheet" href="/style/default">
</head>
<body>
<h1>Kissat</h1>
<nav>
<a href="#">Return to photo index</a>
</nav>
<figure>

<figcaption>Kissat</figcaption>
</figure>
<p>One of them has six toes!</p>
```

```

<p><small><a rel="license" href="http://www.opensource.org/licenses/mit-license.php">MIT  

Licensed</a></small></p>
<footer>
<a href="/">Home</a> | <a href=".../">Photo index</a>
<p><small>© copyright 2009 Exampl Pictures. All Rights Reserved.</small></p>
</footer>
</body>
</html>

```

In this case the [license^{p254}](#) applies to just the photo (the main content of the document), not the whole document. In particular not the design of the page itself, which is covered by the copyright given at the bottom of the document. This could be made clearer in the styling (e.g. making the license link prominently positioned near the photograph, while having the page copyright in light small text at the foot of the page).

Synonyms: For historical reasons, user agents must also treat the keyword "copyright" like the [license^{p254}](#) keyword.

4.6.5.8 Link type "`noreferrer`"

The [noreferrer^{p255}](#) keyword may be used with [a^{p208}](#) and [area^{p390}](#) elements. This keyword does not create a [hyperlink^{p245}](#), but [annotates^{p245}](#) any other hyperlinks created by the element (the implied hyperlink, if no other keywords create one).

The [noreferrer^{p255}](#) keyword indicates that the link is not endorsed by the original author or publisher of the page, or that the link to the referenced document was included primarily because of a commercial relationship between people affiliated with the two pages.

4.6.5.9 Link type "`noreferrerer`"

The [noreferrerer^{p255}](#) keyword may be used with [a^{p208}](#) and [area^{p390}](#) elements. This keyword does not create a [hyperlink^{p245}](#), but [annotates^{p245}](#) any other hyperlinks created by the element (the implied hyperlink, if no other keywords create one).

It indicates that no referrer information is to be leaked when following the link.

If a user agent follows a link defined by an [a^{p208}](#) or [area^{p390}](#) element that has the [noreferrerer^{p255}](#) keyword, the user agent must not include a [Referer^{p49}](#) (sic) HTTP header ([or equivalent^{p83}](#) for other protocols) in the request.

This keyword also [causes the `opener` attribute to remain null^{p767}](#) if the hyperlink [creates^{p762}](#) a new [browsing context^{p762}](#).

4.6.5.10 Link type "`pingback`"

The [pingback^{p255}](#) keyword may be used with [link^{p141}](#) elements. This keyword creates an [external resource link^{p245}](#).

For the semantics of the [pingback^{p255}](#) keyword, see the Pingback 1.0 specification. [\[PINGBACK\]^{p1151}](#)

4.6.5.11 Link type "`prefetch`"

The [prefetch^{p255}](#) keyword may be used with [link^{p141}](#), [a^{p208}](#), and [area^{p390}](#) elements. This keyword creates an [external resource link^{p245}](#).

The [prefetch^{p255}](#) keyword indicates that preemptively fetching and caching the specified resource is likely to be beneficial, as it is highly likely that the user will require this resource.

There is no default type for resources given by the [prefetch^{p255}](#) keyword.

4.6.5.12 Link type "search"

The [search](#)^{p256} keyword may be used with [link](#)^{p141}, [a](#)^{p208}, and [area](#)^{p390} elements. This keyword creates a [hyperlink](#)^{p245}.

The [search](#)^{p256} keyword indicates that the referenced document provides an interface specifically for searching the document and its related resources.

Note OpenSearch description documents can be used with [link](#)^{p141} elements and the [search](#)^{p256} link type to enable user agents to autodiscover search interfaces. [\[OPENSEARCH\]](#)^{p1151}

4.6.5.13 Link type "sidebar"

The [sidebar](#)^{p256} keyword may be used with [link](#)^{p141}, [a](#)^{p208}, and [area](#)^{p390} elements. This keyword creates a [hyperlink](#)^{p245}.

The [sidebar](#)^{p256} keyword indicates that the referenced document, if retrieved, is intended to be shown in a [secondary browsing context](#)^{p764} (if possible), instead of in the current [browsing context](#)^{p762}.

A [hyperlink](#)^{p245} with the [sidebar](#)^{p256} keyword specified is a **sidebar hyperlink**.

4.6.5.14 Link type "stylesheet"

The [stylesheet](#)^{p256} keyword may be used with [link](#)^{p141} elements. This keyword creates an [external resource link](#)^{p245} that contributes to the styling processing model.

The specified resource is a resource that describes how to present the document. Exactly how the resource is to be processed depends on the actual type of the resource.

If the [alternate](#)^{p250} keyword is also specified on the [link](#)^{p141} element, then **the link is an alternative stylesheet**; in this case, the [title](#)^{p122} attribute must be specified on the [link](#)^{p141} element, with a non-empty value.

The default type for resources given by the [stylesheet](#)^{p256} keyword is `text/css`.

The appropriate times to [obtain](#)^{p143} the resource are:

- When the [external resource link](#)^{p245} is created on a [link](#)^{p141} element that is already [in a Document](#)^{p42}.
- When the [external resource link](#)^{p245}'s [link](#)^{p141} element is [inserted into a document](#)^{p42}.
- When the [href](#)^{p142} attribute of the [link](#)^{p141} element of an [external resource link](#)^{p245} that is already [in a Document](#)^{p42} is changed.
- When the [crossorigin](#)^{p142} attribute of the [link](#)^{p141} element of an [external resource link](#)^{p245} that is already [in a Document](#)^{p42} is set, changed, or removed.
- When the [type](#)^{p144} attribute of the [link](#)^{p141} element of an [external resource link](#)^{p245} that is already [in a Document](#)^{p42} is set or changed to a value that does not or no longer matches the [Content-Type metadata](#)^{p86} of the previous obtained external resource, if any.
- When the [type](#)^{p144} attribute of the [link](#)^{p141} element of an [external resource link](#)^{p245} that is already [in a Document](#)^{p42} but was previously not obtained due to the [type](#)^{p144} attribute specifying an unsupported type is set, removed, or changed.
- When the [external resource link](#)^{p245} changes from being [an alternative stylesheet](#)^{p256} to not being one, or vice versa.

Quirk: If the document has been set to [quirks mode](#)^{p51}, has the [same origin](#)^{p778} as the [URL](#)^{p48} of the external resource, and the [Content-Type metadata](#)^{p86} of the external resource is not a supported style sheet type, the user agent must instead assume it to be `text/css`.

Once a resource has been [obtained](#)^{p143}, if its [Content-Type metadata](#)^{p86} is `text/css`, the user agent must run these steps:

1. Let *element* be the [link](#)^{p141} element that created the [external resource link](#)^{p245}.
2. If *element* has an [associated CSS style sheet](#)^{p53}, remove the [CSS style sheet](#)^{p53} in question.

3. If *element* no longer creates an [external resource link^{p245}](#) that contributes to the styling processing model, or if, since the resource in question was [obtained^{p143}](#), it has become appropriate to [obtain^{p143}](#) it again (meaning this algorithm is about to be invoked again for a newly obtained resource), then abort these steps.

4. [Create a CSS style sheet^{p53}](#) with the following properties:

[type^{p53}](#)

text/css

[location^{p53}](#)

The [resulting absolute URL^{p83}](#) determined during the [obtain^{p143}](#) algorithm.

Note This is before any redirects get applied.

[owner node^{p53}](#)

element

[media^{p53}](#)

The [media^{p143}](#) attribute of *element*.

Note This is a reference to the (possibly absent at this time) attribute, rather than a copy of the attribute's current value. The CSSOM specification defines what happens when the attribute is dynamically set, changed, or removed.

[title^{p53}](#)

The [title^{p144}](#) attribute of *element*.

Note This is similarly a reference to the attribute, rather than a copy of the attribute's current value.

[alternate flag^{p53}](#)

Set if [the link is an alternative stylesheet^{p256}](#); unset otherwise.

[origin-clean flag^{p53}](#)

Set if the resource is [CORS-same-origin^{p87}](#); unset otherwise.

[parent CSS style sheet^{p53}](#)

[owner CSS rule^{p53}](#)

null

[disabled flag^{p53}](#)

Left at its default value.

[CSS rules^{p53}](#)

Left uninitialised.

The CSS [environment encoding^{p53}](#) is the result of running the following steps: [\[CSSSYNTAX\]^{p1149}](#)

1. If the element has a [charset^{p1097}](#) attribute, [get an encoding](#) from that attribute's value. If that succeeds, return the resulting encoding and abort these steps. [\[ENCODING\]^{p1150}](#)
2. Otherwise, return the [document's character encoding^{p51}](#). [\[DOM\]^{p1149}](#)

4.6.5.15 Link type "tag"

The [tag^{p257}](#) keyword may be used with [a^{p208}](#) and [area^{p390}](#) elements. This keyword creates a [hyperlink^{p245}](#).

The [tag^{p257}](#) keyword indicates that the *tag* that the referenced document represents applies to the current document.

Note Since it indicates that the *tag* applies to the current document, it would be inappropriate to use this keyword in the markup of a [tag cloud^{p674}](#), which lists the popular tags across a set of pages.

Example

This document is about some gems, and so it is *tagged* with "<http://en.wikipedia.org/wiki/Gemstone>" to unambiguously categorise it as applying to the "jewel" kind of gems, and not to, say, the towns in the US, the Ruby package format, or the Swiss locomotive class:

```
<!DOCTYPE HTML>
<html>
<head>
<title>My Precious</title>
</head>
<body>
<header><h1>My precious</h1> <p>Summer 2012</p></header>
<p>Recently I managed to dispose of a red gem that had been
bothering me. I now have a much nicer blue sapphire.</p>
<p>The red gem had been found in a bauxite stone while I was digging
out the office level, but nobody was willing to haul it away. The
same red gem stayed there for literally years.</p>
<footer>
Tags: <a rel=tag href="http://en.wikipedia.org/wiki/Gemstone">Gemstone</a>
</footer>
</body>
</html>
```

Example

In *this* document, there are two articles. The "[tag^{p257}](#)" link, however, applies to the whole page (and would do so wherever it was placed, including if it was within the [article^{p159}](#) elements).

```
<!DOCTYPE HTML>
<html>
<head>
<title>Gem 4/4</title>
</head>
<body>
<article>
<h1>801: Steinbock</h1>
<p>The number 801 Gem 4/4 electro-diesel has an ibex and was rebuilt in 2002.</p>
</article>
<article>
<h1>802: Murmeltier</h1>
<figure>

<figcaption>The 802 in the 1980s, above Lago Bianco.</figcaption>
</figure>
<p>The number 802 Gem 4/4 electro-diesel has a marmot and was rebuilt in 2003.</p>
</article>
<p class="topic"><a rel=tag href="http://en.wikipedia.org/wiki/Rhaetian_Railway_Gem_4/4">Gem 4/
4</a></p>
</body>
</html>
```

4.6.5.16 Sequential link types

Some documents form part of a sequence of documents.

A sequence of documents is one where each document can have a *previous sibling* and a *next sibling*. A document with no previous sibling is the start of its sequence, a document with no next sibling is the end of its sequence.

A document may be part of multiple sequences.

4.6.5.16.1 Link type "next"

The [next](#)^{p259} keyword may be used with [link](#)^{b141}, [a](#)^{p208}, and [area](#)^{p390} elements. This keyword creates a [hyperlink](#)^{p245}.

The [next](#)^{p259} keyword indicates that the document is part of a sequence, and that the link is leading to the document that is the next logical document in the sequence.

4.6.5.16.2 Link type "prev"

The [prev](#)^{p259} keyword may be used with [link](#)^{b141}, [a](#)^{p208}, and [area](#)^{p390} elements. This keyword creates a [hyperlink](#)^{p245}.

The [prev](#)^{p259} keyword indicates that the document is part of a sequence, and that the link is leading to the document that is the previous logical document in the sequence.

Synonyms: For historical reasons, user agents must also treat the keyword "previous" like the [prev](#)^{p259} keyword.

4.6.5.17 Other link types

Extensions to the predefined set of link types may be registered in the [microformats wiki existing-rel-values page](#). [MFREL]^{p1151}

Anyone is free to edit the microformats wiki existing-rel-values page at any time to add a type. Extension types must be specified with the following information:

Keyword

The actual value being defined. The value should not be confusingly similar to any other defined value (e.g. differing only in case).

If the value contains a U+003A COLON character (:), it must also be an [absolute URL](#)^{p48}.

Effect on... [link](#)^{p141}

One of the following:

Not allowed

The keyword must not be specified on [link](#)^{p141} elements.

Hyperlink

The keyword may be specified on a [link](#)^{p141} element; it creates a [hyperlink](#)^{p245}.

External Resource

The keyword may be specified on a [link](#)^{p141} element; it creates an [external resource link](#)^{p245}.

Effect on... [a](#)^{p208} and [area](#)^{p390}

One of the following:

Not allowed

The keyword must not be specified on [a](#)^{p208} and [area](#)^{p390} elements.

Hyperlink

The keyword may be specified on [a](#)^{p208} and [area](#)^{p390} elements; it creates a [hyperlink](#)^{p245}.

External Resource

The keyword may be specified on [a](#)^{p208} and [area](#)^{p390} elements; it creates an [external resource link](#)^{p245}.

Hyperlink Annotation

The keyword may be specified on [a](#)^{p208} and [area](#)^{p390} elements; it [annotates](#)^{p245} other [hyperlinks](#)^{p245} created by the element.

Brief description

A short non-normative description of what the keyword's meaning is.

Specification

A link to a more detailed description of the keyword's semantics and requirements. It could be another page on the Wiki, or a link to an external page.

Synonyms

A list of other keyword values that have exactly the same processing requirements. Authors should not use the values defined to be synonyms, they are only intended to allow user agents to support legacy content. Anyone may remove synonyms that are not used in practice; only names that need to be processed as synonyms for compatibility with legacy content are to be registered in this way.

Status

One of the following:

Proposed

The keyword has not received wide peer review and approval. Someone has proposed it and is, or soon will be, using it.

Ratified

The keyword has received wide peer review and approval. It has a specification that unambiguously defines how to handle pages that use the keyword, including when they use it in incorrect ways.

Discontinued

The keyword has received wide peer review and it has been found wanting. Existing pages are using this keyword, but new pages should avoid it. The "brief description" and "specification" entries will give details of what authors should use instead, if anything.

If a keyword is found to be redundant with existing values, it should be removed and listed as a synonym for the existing value.

If a keyword is registered in the "proposed" state for a period of a month or more without being used or specified, then it may be removed from the registry.

If a keyword is added with the "proposed" status and found to be redundant with existing values, it should be removed and listed as a synonym for the existing value. If a keyword is added with the "proposed" status and found to be harmful, then it should be changed to "discontinued" status.

Anyone can change the status at any time, but should only do so in accordance with the definitions above.

Conformance checkers must use the information given on the microformats wiki existing-rel-values page to establish if a value is allowed or not: values defined in this specification or marked as "proposed" or "ratified" must be accepted when used on the elements for which they apply as described in the "Effect on..." field, whereas values marked as "discontinued" or not listed in either this specification or on the aforementioned page must be rejected as invalid. Conformance checkers may cache this information (e.g. for performance reasons or to avoid the use of unreliable network connectivity).

When an author uses a new type not defined by either this specification or the Wiki page, conformance checkers should offer to add the value to the Wiki, with the details described above, with the "proposed" status.

Types defined as extensions in the [microformats wiki existing-rel-values page](#) with the status "proposed" or "ratified" may be used with the `rel` attribute on [link^{p141}](#), [a^{p208}](#), and [area^{p390}](#) elements in accordance to the "Effect on..." field. [\[MFREL\]^{p1151}](#)

4.7 Edits

The [ins^{p260}](#) and [del^{p262}](#) elements represent edits to the document.

4.7.1 The `ins` element

Categories^{p113}:

[Flow content^{p115}](#).
[Phrasing content^{p116}](#).
[Palpable content^{p117}](#).

Contexts in which this element can be used^{p113}:

Where [phrasing content^{p116}](#) is expected.

Content model^{p113}:

[Transparent^{p117}](#).

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

Global attributes^{p120}

cite^{p262} — Link to the source of the quotation or more information about the edit

datetime^{p262} — Date and (optionally) time of the change

DOM interface^{p113}:

Uses the HTMLModElement^{p263} interface.

The ins^{p260} element represents^{p111} an addition to the document.

Example

The following represents the addition of a single paragraph:

```
<aside>
  <ins>
    <p> I like fruit. </p>
  </ins>
</aside>
```

As does the following, because everything in the aside^{p166} element here counts as phrasing content^{p116} and therefore there is just one paragraph^{p118}:

```
<aside>
  <ins>
    Apples are <em>tasty</em>.
  </ins>
  <ins>
    So are pears.
  </ins>
</aside>
```

ins^{p260} elements should not cross implied paragraph^{p118} boundaries.

Example

The following example represents the addition of two paragraphs, the second of which was inserted in two parts. The first ins^{p260} element in this example thus crosses a paragraph boundary, which is considered poor form.

```
<aside>
  <!-- don't do this -->
  <ins datetime="2005-03-16 00:00Z">
    <p> I like fruit. </p>
    Apples are <em>tasty</em>.
  </ins>
  <ins datetime="2007-12-19 00:00Z">
    So are pears.
  </ins>
</aside>
```

Here is a better way of marking this up. It uses more elements, but none of the elements cross implied paragraph boundaries.

```
<aside>
  <ins datetime="2005-03-16 00:00Z">
    <p> I like fruit. </p>
  </ins>
  <ins datetime="2005-03-16 00:00Z">
    Apples are <em>tasty</em>.
  </ins>
  <ins datetime="2007-12-19 00:00Z">
```

```
So are pears.  
</ins>  
</aside>
```

4.7.2 The `del` element

Categories^{p113}:

[Flow content^{p115}](#).
[Phrasing content^{p116}](#).

Contexts in which this element can be used^{p113}:

Where [phrasing content^{p116}](#) is expected.

Content model^{p113}:

[Transparent^{p117}](#).

Tag omission in text/html^{p113}:

Neither tag is omissible.

Content attributes^{p113}:

[Global attributes^{p120}](#)

[cite^{p262}](#) — Link to the source of the quotation or more information about the edit

[datetime^{p262}](#) — Date and (optionally) time of the change

DOM interface^{p113}:

Uses the [HTMLModElement^{p263}](#) interface.

The [del^{p262}](#) element [represents^{p111}](#) a removal from the document.

[del^{p262}](#) elements should not cross [implied paragraph^{p118}](#) boundaries.

Example

The following shows a "to do" list where items that have been done are crossed-off with the date and time of their completion.

```
<h1>To Do</h1>  
<ul>  
  <li>Empty the dishwasher</li>  
  <li><del datetime="2009-10-11T01:25-07:00">Watch Walter Lewin's lectures</del></li>  
  <li><del datetime="2009-10-10T23:38-07:00">Download more tracks</del></li>  
  <li>Buy a printer</li>  
</ul>
```

4.7.3 Attributes common to `ins`^{p260} and `del`^{p262} elements

The `cite` attribute may be used to specify the address of a document that explains the change. When that document is long, for instance the minutes of a meeting, authors are encouraged to include a fragment identifier pointing to the specific part of that document that discusses the change.

If the `citep262` attribute is present, it must be a [valid URL potentially surrounded by spaces^{p82}](#) that explains the change. To obtain the corresponding citation link, the value of the attribute must be [resolved^{p82}](#) relative to the element. User agents may allow users to follow such citation links, but they are primarily intended for private use (e.g. by server-side scripts collecting statistics about a site's edits), not for readers.

The `datetime` attribute may be used to specify the time and date of the change.

If present, the `datetimep262` attribute's value must be a [valid date string with optional time^{p77}](#).

User agents must parse the `datetimep262` attribute according to the [parse a date or time string^{p78}](#) algorithm. If that doesn't return a [date^{p67}](#) or a [global date and time^{p72}](#), then the modification has no associated timestamp (the value is non-conforming; it is not a [valid date string with optional](#)

[time](#)^{p77}). Otherwise, the modification is marked as having been made at the given [date](#)^{p67} or [global date and time](#)^{p72}. If the given value is a [global date and time](#)^{p72} then user agents should use the associated time-zone offset information to determine which time zone to present the given datetime in.

This value may be shown to the user, but it is primarily intended for private use.

The [ins](#)^{p260} and [del](#)^{p262} elements must implement the [HTMLModElement](#)^{p263} interface:

IDL	<pre>interface HTMLModElement : HTMLElement { attribute DOMString cite; attribute DOMString dateTime; };</pre>
-----	--

The [cite](#) IDL attribute must [reflect](#)^{p88} the element's [cite](#)^{p262} content attribute. The [dateTime](#) IDL attribute must [reflect](#)^{p88} the element's [datetime](#)^{p262} content attribute.

4.7.4 Edits and paragraphs

This section is non-normative.

Since the [ins](#)^{p260} and [del](#)^{p262} elements do not affect [paragraphing](#)^{p118}, it is possible, in some cases where paragraphs are [implied](#)^{p118} (without explicit [p](#)^{p187} elements), for an [ins](#)^{p260} or [del](#)^{p262} element to span both an entire paragraph or other non-[phrasing content](#)^{p116} elements and part of another paragraph. For example:

```
<section>
<ins>
<p>
  This is a paragraph that was inserted.
</p>
  This is another paragraph whose first sentence was inserted
  at the same time as the paragraph above.
</ins>
  This is a second sentence, which was there all along.
</section>
```

By only wrapping some paragraphs in [p](#)^{p187} elements, one can even get the end of one paragraph, a whole second paragraph, and the start of a third paragraph to be covered by the same [ins](#)^{p260} or [del](#)^{p262} element (though this is very confusing, and not considered good practice):

```
<section>
  This is the first paragraph. <ins>This sentence was
  inserted.
  <p>This second paragraph was inserted.</p>
  This sentence was inserted too.</ins> This is the
  third paragraph in this example.
  <!-- (don't do this) -->
</section>
```

However, due to the way [implied paragraphs](#)^{p118} are defined, it is not possible to mark up the end of one paragraph and the start of the very next one using the same [ins](#)^{p260} or [del](#)^{p262} element. You instead have to use one (or two) [p](#)^{p187} element(s) and two [ins](#)^{p260} or [del](#)^{p262} elements, as for example:

```
<section>
  <p>This is the first paragraph. <del>This sentence was
  deleted.</del></p>
  <p><del>This sentence was deleted too.</del> That
  sentence needed a separate &lt;del&gt; element.</p>
</section>
```

Partly because of the confusion described above, authors are strongly encouraged to always mark up all paragraphs with the [p^{p187}](#) element, instead of having [ins^{p260}](#) or [del^{p262}](#) elements that cross [implied paragraphs^{p118}](#) boundaries.

4.7.5 Edits and lists

This section is non-normative.

The content models of the [ol^{p195}](#) and [ul^{p197}](#) elements do not allow [ins^{p260}](#) and [del^{p262}](#) elements as children. Lists always represent all their items, including items that would otherwise have been marked as deleted.

To indicate that an item is inserted or deleted, an [ins^{p260}](#) or [del^{p262}](#) element can be wrapped around the contents of the [li^{p198}](#) element. To indicate that an item has been replaced by another, a single [li^{p198}](#) element can have one or more [del^{p262}](#) elements followed by one or more [ins^{p260}](#) elements.

Example

In the following example, a list that started empty had items added and removed from it over time. The bits in the example that have been emphasized show the parts that are the "current" state of the list. The list item numbers don't take into account the edits, though.

```
<h1>Stop-ship bugs</h1>
<ol>
  <li><ins datetime="2008-02-12T15:20Z">Bug 225:
    Rain detector doesn't work in snow</ins></li>
  <li><del datetime="2008-03-01T20:22Z"><ins datetime="2008-02-14T12:02Z">Bug 228:
    Water buffer overflows in April</ins></del></li>
  <li><ins datetime="2008-02-16T13:50Z">Bug 230:
    Water heater doesn't use renewable fuels</ins></li>
  <li><del datetime="2008-02-20T21:15Z"><ins datetime="2008-02-16T14:25Z">Bug 232:
    Carbon dioxide emissions detected after startup</ins></del></li>
</ol>
```

Example

In the following example, a list that started with just fruit was replaced by a list with just colours.

```
<h1>List of <del>fruits</del><ins>colours</ins></h1>
<ul>
  <li><del>Lime</del><ins>Green</ins></li>
  <li><del>Apple</del></li>
  <li>Orange</li>
  <li><del>Pear</del></li>
  <li><ins>Teal</ins></li>
  <li><del>Lemon</del><ins>Yellow</ins></li>
  <li>Olive</li>
  <li><ins>Purple</ins></li>
</ul>
```

4.7.6 Edits and tables

This section is non-normative.

The elements that form part of the table model have complicated content model requirements that do not allow for the [ins^{p260}](#) and [del^{p262}](#) elements, so indicating edits to a table can be difficult.

To indicate that an entire row or an entire column has been added or removed, the entire contents of each cell in that row or column can be wrapped in [ins^{p260}](#) or [del^{p262}](#) elements (respectively).

Example

Here, a table's row has been added:

```

<table>
  <thead>
    <tr> <th> Game name <th> Game publisher <th> Verdict
  <tbody>
    <tr> <td> Diablo 2 <td> Blizzard <td> 8/10
    <tr> <td> Portal <td> Valve <td> 10/10
    <tr> <td> <ins>Portal 2</ins> <td> <ins>Valve</ins> <td> <ins>10/10</ins>
  </tbody>
</table>

```

Here, a column has been removed (the time at which it was removed is given also, as is a link to the page explaining why):

```

<table>
  <thead>
    <tr> <th> Game name <th> Game publisher <th> <del cite="/edits/r192">Verdict</del>
    <th> <del cite="/edits/r192">datetime="2011-05-02 14:23Z">Verdict</del>
  <tbody>
    <tr> <td> Diablo 2 <td> Blizzard <td> <del cite="/edits/r192">8/10</del>
    <td> <del cite="/edits/r192">datetime="2011-05-02 14:23Z">8/10</del>
    <tr> <td> Portal <td> Valve <td> <del cite="/edits/r192">10/10</del>
    <td> <del cite="/edits/r192">datetime="2011-05-02 14:23Z">10/10</del>
    <tr> <td> Portal 2 <td> Valve <td> <del cite="/edits/r192">10/10</del>
    <td> <del cite="/edits/r192">datetime="2011-05-02 14:23Z">10/10</del>
  </tbody>
</table>

```

Generally speaking, there is no good way to indicate more complicated edits (e.g. that a cell was removed, moving all subsequent cells up or to the left).

4.8 Embedded content

4.8.1 Introduction

This section is non-normative.

To embed an image in HTML, when there is only a single image resource, use the `imgp272` element and its `srcp273` attribute.

Example

```

<h2>From today's featured article</h2>

<p><b><a href="/wiki/Marie_Lloyd">Marie Lloyd</a></b> (1870–1922)
was an English <a href="/wiki/Music_hall">music hall</a> singer, ...

```

However, there are a number of situations for which the author might wish to use multiple image resources that the user agent can choose from:

- Different users might have different environmental characteristics:
 - The users' physical screen size might be different from one another.

Example A mobile phone's screen might be 4 inches diagonally, while a laptop's screen might be 14 inches diagonally.

Note *This is only relevant when an image's rendered size depends on the viewport size.*

- The users' screen pixel density might be different from one another.

Example A mobile phone's screen might have three times as many physical pixels per inch compared to another mobile phone's screen, regardless of their physical screen size.

- The users' zoom level might be different from one another, or might change for a single user over time.

Example A user might zoom in to a particular image to be able to get a more detailed look.

The zoom level and the screen pixel density (the previous point) can both affect the number of physical screen pixels per CSS pixel. This ratio is usually referred to as **device-pixel-ratio**.

- The users' screen orientation might be different from one another, or might change for a single user over time.

Example A tablet can be held upright or rotated 90 degrees, so that the screen is either "portrait" or "landscape".

- The users' network speed, network latency and bandwidth cost might be different from one another, or might change for a single user over time.

Example A user might be on a fast, low-latency and constant-cost connection while at work, on a slow, low-latency and constant-cost connection while at home, and on a variable-speed, high-latency and variable-cost connection anywhere else.

- Authors might want to show the same image content but with different rendered size depending on, usually, the width of the viewport. This is usually referred to as **viewport-based selection**.

Example A Web page might have a banner at the top that always spans the entire viewport width. In this case, the rendered size of the image depends on the physical size of the screen (assuming a maximised browser window).

Example Another Web page might have images in columns, with a single column for screens with a small physical size, two columns for screens with medium physical size, and three columns for screens with big physical size, with the images varying in rendered size in each case to fill up the viewport. In this case, the rendered size of an image might be *bigger* in the one-column layout compared to the two-column layout, despite the screen being smaller.

- Authors might want to show different image content depending on the rendered size of the image. This is usually referred to as **art direction**.

Example When a Web page is viewed on a screen with a large physical size (assuming a maximised browser window), the author might wish to include some less relevant parts surrounding the critical part of the image. When the same Web page is viewed on a screen with a small physical size, the author might wish to show only the critical part of the image.

- Authors might want to show the same image content but using different image formats, depending on which image formats the user agent supports. This is usually referred to as **image format-based selection**.

Example A Web page might have some images in the JPEG, WebP and JPEG XR image formats, with the latter two having better compression abilities compared to JPEG. Since different user agents can support different image formats, with some formats offering better compression ratios, the author would like to serve the better formats to user agents that support them, while providing JPEG fallback for user agents that don't.

The above situations are not mutually exclusive. For example, it is reasonable to combine different resources for different [device-pixel-ratio^{p265}](#) with different resources for [art direction^{p266}](#).

While it is possible to solve these problems using scripting, doing so introduces some other problems:

- Some user agents aggressively download images specified in the HTML markup, before scripts have had a chance to run, so that Web pages complete loading sooner. If a script changes which image to download, the user agent will potentially start two separate downloads, which can instead cause worse page loading performance.
- If the author avoids specifying any image in the HTML markup and instead instantiates a single download from script, that avoids the double download problem above but then no image will be downloaded at all for users with scripting disabled and the aggressive image downloading optimisation will also be disabled.

With this in mind, this specification introduces a number of features to address the above problems in a declarative manner.

[Device-pixel-ratio^{p265}-based selection when the rendered size of the image is fixed](#)

The [src^{p273}](#) and [srcset^{p273}](#) attributes on the [img^{p272}](#) element can be used, using the `x` descriptor, to provide multiple images that only vary in their size (the smaller image is a scaled-down version of the bigger image).

Note *The `x` descriptor is not appropriate when the rendered size of the image depends on the viewport width ([viewport-based selection^{p266}](#)), but can be used together with [art direction^{p266}](#).*

Example

```
<h2>From today's featured article</h2>

```

```
<p><b><a href="/wiki/Marie_Lloyd">Marie Lloyd</a></b> (1870–1922)  
was an English <a href="/wiki/Music_hall">music hall</a> singer, ...
```

The user agent can choose any of the given resources depending on the user's screen's pixel density, zoom level, and possibly other factors such as the user's network conditions.

For backwards compatibility with older user agents that don't yet understand the `srcset`^{p273} attribute, one of the URLs is specified in the `img`^{p272} element's `src`^{p273} attribute. This will result in something useful (though perhaps lower-resolution than the user would like) being displayed even in older user agents. For new user agents, the `src`^{p273} attribute participates in the resource selection, as if it was specified in `srcset`^{p273} with a `1x` descriptor.

The image's rendered size is given in the `width`^{p397} and `height`^{p397} attributes, which allows the user agent to allocate space for the image before it is downloaded.

Viewport-based selection^{p266}

The `srcset`^{p273} and `sizes`^{p274} attributes can be used, using the `w` descriptor, to provide multiple images that only vary in their size (the smaller image is a scaled-down version of the bigger image).

Example In this example, a banner image takes up the entire viewport width (using appropriate CSS).

```
<h1></h1>
```

The user agent will calculate the effective pixel density of each image from the specified `w` descriptors and the specified rendered size in the `sizes`^{p274} attribute. It can then choose any of the given resources depending on the user's screen's pixel density, zoom level, and possibly other factors such as the user's network conditions.

If the user's screen is 320 CSS pixels wide, this is equivalent to specifying `wolf-400.jpg 1.25x`, `wolf-800.jpg 2.5x`, `wolf-1600.jpg 5x`. On the other hand, if the user's screen is 1200 CSS pixels wide, this is equivalent to specifying `wolf-400.jpg 0.33x`, `wolf-800.jpg 0.67x`, `wolf-1600.jpg 1.33x`. By using the `w` descriptors and the `sizes`^{p274} attribute, the user agent can choose the correct image source to download regardless of how large the user's device is.

For backwards compatibility, one of the URLs is specified in the `img`^{p272} element's `src`^{p273} attribute. In new user agents, the `src`^{p273} attribute is ignored when the `srcset`^{p273} attribute uses `w` descriptors.

Example In this example, the Web page has three layouts depending on the width of the viewport. The narrow layout has one column of images (the width of each image is about 100%), the middle layout has two columns of images (the width of each image is about 50%), and the widest layout has three columns of images, and some page margin (the width of each image is about 33%). It breaks between these layouts when the viewport is `30em` wide and `50em` wide, respectively.

```

```

The `sizes`^{p274} attribute sets up the layout breakpoints at `30em` and `50em`, and declares the image sizes between these breakpoints to be `100vw`, `50vw`, or `calc(33vw - 100px)`. These sizes do not necessarily have to match up exactly with the actual image width as specified in the CSS.

The user agent will pick a width from the `sizes`^{p274} attribute, using the first item with a `<media-condition>`^{p270} (the part in parentheses) that evaluates to true, or using the last item (`calc(33vw - 100px)`) if they all evaluate to false.

For example, if the viewport width is `29em`, then `(max-width: 30em)` evaluates to true and `100vw` is used, so the image size, for the purpose of resource selection, is `29em`. If the viewport width is instead `32em`, then `(max-width: 30em)` evaluates to false, but `(max-width: 50em)` evaluates to true and `50vw` is used, so the image size, for the purpose of resource selection, is `16em` (half the viewport width). Notice that the slightly wider viewport results in a smaller image because of the different layout.

The user agent can then calculate the effective pixel density and choose an appropriate resource similarly to the previous example.

Art direction^{p266}-based selection

The picture^{p270} element and the source^{p271} element, together with the media^{p271} attribute, can be used, to provide multiple images that vary the image content (for instance the smaller image might be a cropped version of the bigger image).

Example

```
<picture>
  <source media="(min-width: 45em)" srcset="large.jpg">
  <source media="(min-width: 32em)" srcset="med.jpg">
  
</picture>
```

The user agent will choose the first source^{p271} element for which the media query in the media^{p271} attribute matches, and then choose an appropriate URL from its srcset^{p271} attribute.

The rendered size of the image varies depending on which resource is chosen. To specify dimensions that the user agent can use before having downloaded the image, CSS can be used.

CSS

```
img { width: 300px; height: 300px }
@media (min-width: 32em) { img { width: 500px; height: 300px } }
@media (min-width: 45em) { img { width: 700px; height: 400px } }
```

Example

This example combines art direction^{p266}- and device-pixel-ratio^{p265}-based selection. A banner that takes half the viewport is provided in two versions, one for wide screens and one for narrow screens.

```
<h1>
<picture>
  <source media="(max-width: 500px)" srcset="banner-phone.jpeg, banner-phone-HD.jpeg 2x">
  
</picture>
</h1>
```

Image format-based selection^{p266}

The type^{p271} attribute on the source^{p271} element can be used, to provide multiple images in different formats.

Example

```
<h2>From today's featured article</h2>
<picture>
  <source srcset="/uploads/100-marie-lloyd.webp" type="image/webp">
  <source srcset="/uploads/100-marie-lloyd.jxr" type="image/vnd.ms-photo">
  
</picture>
<p><b><a href="/wiki/Marie_Lloyd">Marie Lloyd</a></b> (1870–1922)
was an English <a href="/wiki/Music_hall">music hall</a> singer, ...
```

In this example, the user agent will choose the first source that has a type^{p271} attribute with a supported MIME type. If the user agent supports WebP images, the first source^{p271} element will be chosen. If not, but the user agent does support JPEG XR images, the second source^{p271} element will be chosen. If neither of those formats are supported, the img^{p272} element will be chosen.

4.8.1.1 Adaptive images

This section is non-normative.

CSS and media queries can be used to construct graphical page layouts that adapt dynamically to the user's environment, in particular to different viewport dimensions and pixel densities. For content, however, CSS does not help; instead, we have the img^{p272} element's srcset^{p273} attribute and the picture^{p270} element. This section walks through a sample case showing how to use these features.

Consider a situation where on wide screens (wider than 600 CSS pixels) a 300×150 image named `a-rectangle.png` is to be used, but on smaller screens (600 CSS pixels and less), a smaller 100×100 image called `a-square.png` is to be used. The markup for this would look like this:

```

<figure>
  <picture>
    <source srcset="a-square.png" media="(max-width: 600px)">
      
    </picture>
    <figcaption>Barney Frank, 2011</figcaption>
  </figure>

```

Note For details on what to put in the [alt^{p273}](#) attribute, see the [Requirements for providing text to act as an alternative for images^{p288}](#) section.

The problem with this is that the user agent does not necessarily know what dimensions to use for the image when the image is loading. To avoid the layout having to be reflowed multiple times as the page is loading, CSS and CSS media queries can be used to provide the dimensions:

```

<figure>
  <style scoped>
    #a { width: 300px; height: 150px; }
    @media (max-width: 600px) { #a { width: 100px; height: 100px; } }
  </style>
  <picture>
    <source srcset="a-square.png" media="(max-width: 600px)">
      
    </picture>
    <figcaption>Barney Frank, 2011</figcaption>
  </figure>

```

Alternatively, the [width^{p397}](#) and [height^{p397}](#) attributes can be used to provide the width for legacy user agents, using CSS just for the user agents that support [picture^{p270}](#):

```

<figure>
  <style scoped media="(max-width: 600px)">
    #a { width: 100px; height: 100px; }
  </style>
  <picture>
    <source srcset="a-square.png" media="(max-width: 600px)">
      
    </picture>
    <figcaption>Barney Frank, 2011</figcaption>
  </figure>

```

The [source^{p271}](#) element is used with the [src^{p273}](#) attribute, which gives the URL of the image to use for legacy user agents that do not support the [picture^{p270}](#) element. This leads to a question of which image to provide in the [src^{p273}](#) attribute.

If the author wants the biggest image in legacy user agents, the markup could be as follows:

```

<picture>
  <source srcset="pear-mobile.jpeg" media="(max-width: 720px)">
  <source srcset="pear-tablet.jpeg" media="(max-width: 1280px)">
  
</picture>

```

However, if legacy mobile user agents are more important, one can list all three images in the [source^{p271}](#) elements, overriding the [src^{p273}](#) attribute entirely.

```

<picture>
  <source srcset="pear-mobile.jpeg" media="(max-width: 720px)">
  <source srcset="pear-tablet.jpeg" media="(max-width: 1280px)">
  <source srcset="pear-desktop.jpeg">
  
</picture>

```

Since at this point the `src`^{p273} attribute is actually being ignored entirely by `picture`-supporting user agents, the `src`^{p273} attribute can default to any image, including one that is neither the smallest nor biggest:

```
<picture>
  <source srcset="pear-mobile.jpeg" media="(max-width: 720px)">
  <source srcset="pear-tablet.jpeg" media="(max-width: 1280px)">
  <source srcset="pear-desktop.jpeg">
  
</picture>
```

Above the `max-width` media feature is used, giving the maximum (viewport) dimensions that an image is intended for. It is also possible to use `min-width` instead.

```
<picture>
  <source srcset="pear-desktop.jpeg" media="(min-width: 1281px)">
  <source srcset="pear-tablet.jpeg" media="(min-width: 721px)">
  
</picture>
```

DOM interface^{p113}:

IDL	interface <code>HTMLPictureElement</code> : <code>HTMLElement</code> {};
-----	--

The `picture`^{p270} element is a container which provides multiple sources to its contained `img`^{p272} element to allow authors to declaratively control or give hints to the user agent about which image resource to use, based on the screen pixel density, viewport size, image format, and other factors. It represents^{p111} its children.

Note *The `picture`^{p270} element is somewhat different from the similar-looking `video`^{p317} and `audio`^{p321} elements. While all of them contain `source`^{p271} elements, the `source`^{p271} element's `src`^{p322} attribute has no meaning when the element is nested within a `picture`^{p270} element, and the resource selection algorithm is different. As well, the `picture`^{p270} element itself does not display anything; it merely provides a context for its contained `img`^{p272} element that enables it to choose from multiple URLs^{p48}.*

4.8.4 The `source` element when used with the `picture`^{p270} element

Categories^{p113}:

Same as for the `source`^{p322} element.

Contexts in which this element can be used^{p113}:

As a child of a `picture`^{p270} element, before the `img`^{p272} element.

Content model^{p113}:

Same as for the `source`^{p322} element.

Content attributes^{p113}:

`Global attributes`^{p120}

`srcset`^{p271}

`sizes`^{p271}

`media`^{p271}

`type`^{p271}

DOM interface^{p113}:

IDL	partial interface <code>HTMLSourceElement</code> { attribute DOMString <code>srcset</code> ; attribute DOMString <code>sizes</code> ; attribute DOMString <code>media</code> ; };
-----	---

The authoring requirements in this section only apply if the `source`^{p271} element has a parent that is a `picture`^{p270} element.

The `source`^{p271} element allows authors to specify multiple alternative `source sets`^{p279} for `img`^{p272} elements. It does not represent^{p111} anything on its own.

The `srcset` attribute must be present, and must consist of one or more `image candidate strings`^{p273}, each separated from the next by a U+002C COMMA character (,). If an `image candidate string`^{p273} contains no descriptors and no `space characters`^{p58} after the URL, the following `image candidate string`^{p273}, if there is one, must begin with one or more `space characters`^{p58}. Spec bugs: [26539](#)

If the `srcset`^{p271} attribute has any `image candidate strings`^{p273} using a `width descriptor`, the `sizes` attribute must also be present and the value must be a `valid source size list`^{p274}. Spec bugs: [26537](#)

The `media` attributes may also be present. If present, the value must contain a `valid media query list`^{p81}. Spec bugs: [26538](#)

The `type` attribute may also be present. If present, the value must be a `valid MIME type`^{p42}. It gives the type of the images in the `source set`^{p279}, to allow the user agent to skip to the next `source`^{p271} element if it does not support the given type.

Note If the `type`^{p271} attribute is not specified, the user agent will not select a different `source`^{p271} element if it finds that it does not support the image format after fetching it.

When a `source`^{p271} element has a following sibling `source`^{p271} element or `img`^{p272} element with a `srcset`^{p273} attribute specified, it must have at least one of the following:

- A `media`^{p271} attribute specified with a value that, after [stripping leading and trailing whitespace](#)^{p59}, is not the empty string and is not an [ASCII case-insensitive](#)^{p58} match for the string "all".
- A `type`^{p271} attribute specified.

The `src`^{p322} attribute must not be present.

The IDL attributes `srcset`, `sizes` and `media` must [reflect](#)^{p88} the respective content attributes of the same name.

4.8.5 The `img` element

Spec bugs: [24055](#), [26068](#),

readonly attribute boolean complete;
readonly attribute DOMString currentSrc;

// also has obsolete members
};

```

Spec bugs: [26701](#)

An img^{p272} element represents an image.

The image given by the src and srcset attributes, and any previous sibling source^{p271} elements' srcset^{p271} attributes if the parent is a picture^{p270} element, is the embedded content; the value of the alt attribute provides equivalent content for those who cannot process images or who have image loading disabled (i.e. it is the img^{p272} element's fallback content^{p116}).

The requirements on the alt^{p273} attribute's value are described [in the next section](#)^{p288}.

The src^{p273} attribute must be present, and must contain a valid non-empty URL potentially surrounded by spaces^{p82} referencing optionally animated, image resource that is neither paged nor scripted.

The srcset^{p273} attribute may also be present. If present, its value must consist of one or more image candidate strings^{p273}, each the next by a U+002C COMMA character (,),. If an image candidate string^{p273} contains no descriptors and no space characters^{p58} following image candidate string^{p273}, if there is one, must begin with one or more space characters^{p58}.

Source: [caniuse.com](#)

An **image candidate string** consists of the following components, in order, with the further restrictions described below this list:

1. Zero or more space characters^{p58}.
2. A valid non-empty URL^{p82} that does not start or end with a U+002C COMMA character (,), referencing a non-interactive, optionally animated, image resource that is neither paged nor scripted.
3. Zero or more space characters^{p58}.
4. Zero or one of the following:
 - A *width descriptor*, consisting of: a space character^{p58}, a valid non-negative integer^{p61} giving a number greater than zero representing the *width descriptor* value, and a U+0077 LATIN SMALL LETTER W character.
 - A *pixel density descriptor*, consisting of: a space character^{p58}, a valid floating-point number^{p61} giving a number greater than zero representing the *pixel density descriptor* value, and a U+0078 LATIN SMALL LETTER X character.
5. Zero or more space characters^{p58}.

There must not be an image candidate string^{p273} for an element that has the same *width descriptor* value as another image candidate string^{p273}'s *width descriptor* value for the same element.

There must not be an image candidate string^{p273} for an element that has the same *pixel density descriptor* value as another image candidate string^{p273}'s *pixel density descriptor* value for the same element. For the purpose of this requirement, an image candidate string^{p273} with no descriptors is equivalent to an image candidate string^{p273} with a `1x` descriptor.

If a source^{p271} element has a sizes^{p271} attribute present or an img^{p272} element has a sizes^{p274} attribute present, all image candidate strings^{p273} for that element must have the *width descriptor* specified.

If an image candidate string^{p273} for an source^{p271} or img^{p272} element has the *width descriptor* specified, all other image candidate strings^{p273} for that element must also have the *width descriptor* specified.

The specified width in an image candidate string^{p273}'s *width descriptor* must match the intrinsic width in the resource given by the image candidate string^{p273}'s URL, if it has an intrinsic width.

Note The requirements above imply that images can be static bitmaps (e.g. PNGs, GIFs, JPEGs), single-page vector documents (single-page PDFs, XML files with an SVG root element), animated bitmaps (APNGs, animated GIFs), animated vector graphics (XML files with an SVG

(root element that use declarative SMIL animation), and so forth. However, these definitions preclude SVG files with script, multipage PDF files, interactive MNG files, HTML documents, plain text documents, and so forth. [PNG]^{p1151} [GIF]^{p1150} [JPEG]^{p1150} [PDF]^{p1151} [XML]^{p1154} [APNG]^{p1148} [SVG]^{p1153} [MNG]^{p1151}

If the `srcset`^{p273} attribute is present and has any `image candidate strings`^{p273} using a `width descriptor`, the `sizes` attribute must also be present, and the value must be a `valid source size list`^{p274}.

A `valid source size list` is a string that matches the following grammar: [CSSVALUES]^{p1149} [MQ]^{p1151}

```
<source-size-list> = [ <source-size># , ]? <source-size-value>
<source-size> = <media-condition> <source-size-value>
<source-size-value> = <length>
```

A `<source-size-value>`^{p274} must not be negative.

Note Percentages are not allowed in a `<source-size-value>`^{p274}, to avoid confusion about what it would be relative to. The `vw` unit can be used for sizes relative to the viewport width.

The `img`^{p272} element must not be used as a layout tool. In particular, `img`^{p272} elements should not be used to display transparent images, as such images rarely convey meaning and rarely add anything useful to the document.

The `crossorigin` attribute is a `CORS settings attribute`^{p87}. Its purpose is to allow images from third-party sites that allow cross-origin access to be used with `canvas`^{p607}.

An `img`^{p272} element has a `current request` and a `pending request`. The `current request`^{p274} is initially set to a new `image request`^{p274}. The `pending request`^{p274} is initially set to null. The `current request`^{p274} is usually referred to as the `img`^{p272} element itself. Spec bugs: 27484

An `image request` has a `state`, `current URL` and `image data`.

An `image request`^{p274}'s `state`^{p274} is one of the following:

Unavailable

The user agent hasn't obtained any image data, or has obtained some or all of the image data but hasn't yet decoded enough of the image to get the image dimensions.

Partially available

The user agent has obtained some of the image data and at least the image dimensions are available.

Completely available

The user agent has obtained all of the image data and at least the image dimensions are available.

Broken

The user agent has obtained all of the image data that it can, but it cannot even decode the image enough to get the image dimensions (e.g. the image is corrupted, or the format is not supported, or no data could be obtained).

An `image request`^{p274}'s `current URL`^{p274} is initially the empty string.

An `image request`^{p274}'s `image data`^{p274} is the decoded image data.

When an `image request`^{p274} is either in the `partially available`^{p274} state or in the `completely available`^{p274} state, it is said to be **available**.

An `image request`^{p274} is initially `unavailable`^{p274}.

When an `img`^{p272} element is `available`^{p274}, it provides a paint source^{p53} whose width is the image's `density-corrected intrinsic width`^{p275} (if any), whose height is the image's `density-corrected intrinsic height`^{p275} (if any), and whose appearance is the intrinsic appearance of the image.

In a `browsing context`^{p762} where `scripting is disabled`^{p828}, user agents may obtain images immediately or on demand. In a `browsing context`^{p762} where `scripting is enabled`^{p828}, user agents must obtain images immediately.

A user agent that obtains images immediately must synchronously `update the image data`^{p275} of an `img`^{p272} element, with the `restart animation` flag set if so stated, whenever that element is created or has experienced `relevant mutations`^{p275}.

A user agent that obtains images on demand must [update the image data](#)^{p275} of an [img](#)^{p272} element whenever it needs the image data (i.e. on demand), but only if the [img](#)^{p272} element is in the [unavailable](#)^{p274} state. When an [img](#)^{p272} element has experienced [relevant mutations](#)^{p275}, if the user agent only obtains images on demand, the [img](#)^{p272} element must return to the [unavailable](#)^{p274} state.

The [relevant mutations](#) for an [img](#)^{p272} element are as follows:

- The element's [src](#)^{p273}, [srcset](#)^{p273} or [sizes](#)^{p274} attributes are set, changed, or removed.
- The element's [src](#)^{p273} attribute is set to the same value as the previous value. This must set the *restart animation* flag for the [update the image data](#)^{p275} algorithm.
- The element's [crossorigin](#)^{p274} attribute's state is changed.
- The [element is inserted](#)^{p43} into or [removed](#)^{p43} from a [picture](#)^{p270} parent element.
- The element's parent is a [picture](#)^{p270} element and a [source](#)^{p271} [element is inserted](#)^{p43} as a previous sibling.
- The element's parent is a [picture](#)^{p270} element and a [source](#)^{p271} element that was a previous sibling is [removed](#)^{p43}.
- The element's parent is a [picture](#)^{p270} element and a [source](#)^{p271} element that is a previous sibling has its [srcset](#)^{p271}, [sizes](#)^{p271}, [media](#)^{p271} or [type](#)^{p271} attributes set, changed, or removed.
- The element's [adopting steps](#) are run.

Each [img](#)^{p272} element has a **last selected source**, which must initially be null.

Each [image request](#)^{p274} has a **current pixel density**, which must initially be undefined.

When an [img](#)^{p272} element has a [current pixel density](#)^{p275} that is not 1.0, the element's image data must be treated as if its resolution, in device pixels per CSS pixels, was the [current pixel density](#)^{p275}. The image's **density-corrected intrinsic width and height** are the intrinsic width and height after taking into account the [current pixel density](#)^{p275}.

Example For example, if the [current pixel density](#)^{p275} is 3.125, that means that there are 300 device pixels per CSS inch, and thus if the image data is 300x600, it has an intrinsic dimension of 96 CSS pixels by 192 CSS pixels.

Each [Document](#)^{p102} object must have a **list of available images**. Each image in this list is identified by a tuple consisting of an [absolute URL](#)^{p48}, a [CORS settings attribute](#)^{p87} mode, and, if the mode is not [No CORS](#)^{p87}, an [origin](#)^{p776}. Each image furthermore has an [ignore higher-layer caching](#) flag. User agents may copy entries from one [Document](#)^{p102} object's [list of available images](#)^{p275} to another at any time (e.g. when the [Document](#)^{p102} is created, user agents can add to it all the images that are loaded in other [Document](#)^{p102}s), but must not change the keys of entries copied in this way when doing so, and must unset the [ignore higher-layer caching](#)^{p275} flag for the copied entry. User agents may also remove images from such lists at any time (e.g. to save memory). User agents must remove entries in the [list of available images](#)^{p275} as appropriate given higher-layer caching semantics for the resource (e.g. the HTTP `Cache-Control` response header) when the [ignore higher-layer caching](#)^{p275} is unset.

Note The [list of available images](#)^{p275} is intended to enable synchronous switching when changing the [src](#)^{p273} attribute to a URL that has previously been loaded, and to avoid re-downloading images in the same document even when they don't allow caching per HTTP. It is not used to avoid re-downloading the same image while the previous image is still loading, but the [fetch](#)^{p84} algorithm allows the download to be reused in that case.

Note The user agent can also store the image data separately from the [list of available images](#)^{p275}.

Example For example, if a resource has the HTTP response header `Cache-Control: must-revalidate`, the user agent would remove it from the [list of available images](#)^{p275} but could keep the image data separately, and use that if the server responds with a `304 Not Modified` status.

When the user agent is to [update the image data](#) of an [img](#)^{p272} element, optionally with the *restart animations* flag set, it must run the following steps:

1. If the element's [node document](#) is not the [active document](#)^{p762}, then run these substeps:
 1. Continue running this algorithm [in parallel](#)^{p41}.
 2. Wait until the element's [node document](#) is the [active document](#)^{p762}.

Spec bugs: [24597](#), [24712](#)

:

3. If another instance of this algorithm for this `img` element was started after this instance (even if it aborted and is no longer running), then abort these steps.
4. **Queue a microtask** to continue this algorithm.
2. If the user agent cannot support images, or its support for images has been disabled, then **abort the image request** for the `current request` and the `pending request`, set `current request` to the `unavailable` state, let `pending request` be null, and abort these steps.
3. If the element does not have a `srcset` attribute specified and it does not have a parent or it has a parent but it is not a `picture` element, and it has a `src` attribute specified and its value is not the empty string, let `selected source` be the value of the element's `src` attribute, and `selected pixel density` be 1.0. Otherwise, let `selected source` be null and `selected pixel density` be undefined.
4. Let the `img` element's `last selected source` be `selected source`.
5. If `selected source` is not null, run these substeps:
 1. **Resolve** `selected source`, relative to the element, and let the result be *absolute URL*. If that is not successful, then abort these inner set of steps.
 2. Let `key` be a tuple consisting of the resulting *absolute URL*, the `img` element's `crossorigin` attribute's mode, and, if that mode is not `No CORS`, the `node document`'s `origin`.
 3. If the `list of available images` contains an entry for `key`, then set the `ignore higher-layer caching` flag for that entry, **abort the image request** for the `current request` and the `pending request`, let `pending request` be null, let `current request` be a new `image request` whose `image data` is that of the entry and whose state is set to the `completely available` state, update the presentation of the image appropriately, let the `current request`'s `current pixel density` be `selected pixel density`, **queue a task** to **restart the animation** if `restart animation` is set, change `current request`'s `current URL` to *absolute URL*, and then **fire a simple event** named `load` at the `img` element, and abort these steps.
6. **Await a stable state**, allowing the `task` that invoked this algorithm to continue. The `synchronous section` consists of all the remaining steps of this algorithm until the algorithm says the `synchronous section` has ended. (Steps in `synchronous sections` are marked with \boxtimes .)
7. \boxtimes If another instance of this algorithm for this `img` element was started after this instance (even if it aborted and is no longer running), then abort these steps.

Note Only the last instance takes effect, to avoid multiple requests when, for example, the `src`, `srcset`, and `crossorigin` attributes are all set in succession.

8. \boxtimes Let `selected source` and `selected pixel density` be the URL and pixel density that results from **selecting an image source**, respectively.
9. \boxtimes If `selected source` is null, run these substeps:
 1. \boxtimes Set the `current request` to the `broken` state, **abort the image request** for the `current request` and the `pending request`, and let `pending request` be null.
 2. \boxtimes **Queue a task** to change the `current request`'s `current URL` to the empty string, and then, if the element has a `src` attribute or a `srcset` attribute or a parent that is a `picture` element, **fire a simple event** named `error` at the `img` element.
 3. \boxtimes Abort this algorithm.
10. \boxtimes **Queue a task** to **fire a progress event** named `loadstart` at the `img` element.
11. \boxtimes **Resolve** `selected source`, relative to the element, and let the result be *absolute URL*. If that is not successful, then **abort the image request** for the `current request` and the `pending request`, set the `current request` to the `broken` state, let `pending request` be null, **queue a task** to change the `current request`'s `current URL` to *absolute URL*, **fire a simple event** named `error` at the `img` element and then **fire a simple event** named `loadend` at the `img` element, and abort these steps.
12. \boxtimes If the `pending request` is not null, and *absolute URL* is the same as the `pending request`'s `current URL`, then abort these steps.

☒ If *absolute URL* is the same as the *current request*^{p274}'s *current URL*^{p274}, and *current request*^{p274} is in the *partially available*^{p274} state, then *abort the image request*^{p278} for the *pending request*^{p274}, *queue a task*^{p835} to *restart the animation*^{p1080} if *restart animation* is set, and abort these steps.

☒ If the *pending request*^{p274} is not null, *abort the image request*^{p278} for the *pending request*^{p274}.

☒ Let *image request* be a new *image request*^{p274} whose *current URL*^{p274} is *absolute URL*.

☒ If *current request*^{p274} is in the *unavailable*^{p274} state or the *broken*^{p274} state, let the *current request*^{p274} be *image request*. Otherwise, let the *pending request*^{p274} be *image request*.

☒ Do a *potentially CORS-enabled fetch*^{p87} of *absolute URL*, with the *mode* being the current state of the element's *crossorigin*^{p274} content attribute, the *origin* being the *origin*^{p776} of the *img*^{p272} element's *node document*, and the *default origin behaviour* set to *taint*. Let this instance of the *fetching*^{p84} algorithm be associated with *image request*.

If the element has a *srcset*^{p273} attribute or a parent that is a *picture*^{p270} element, the fetching request's *context*^{p270} must be set to *imageset*. Otherwise it must be set to *image*. [FETCH]^{p1150}

This specification does not yet use the "fetch" algorithm from the WHATWG Fetch specification. It will be updated to do so in due course.

The resource obtained in this fashion, if any, is *image request*'s *image data*^{p274}. It can be either *CORS-same-origin*^{p87} or *CORS-cross-origin*^{p87}; this affects the *origin*^{p776} of the image itself (e.g. when used on a *canvas*^{p607}).

Fetching the image must *delay the load event*^{p1033} of the element's *node document* until the *task*^{p834} that is *queued*^{p835} by the *networking task source*^{p839} once the resource has been *fetched*^{p84} (defined below^{p278}) has been run.

⚠️Warning! This, unfortunately, can be used to perform a rudimentary port scan of the user's local network (especially in conjunction with scripting, though scripting isn't actually necessary to carry out such an attack). User agents may implement *cross-origin*^{p776} access control policies that are stricter than those described above to mitigate this attack, but unfortunately such policies are typically not compatible with existing Web content.

If the resource is *CORS-same-origin*^{p87}, each *task*^{p834} that is *queued*^{p835} by the *networking task source*^{p839} while the image is being *fetched*^{p84}, if *image request* is the *current request*^{p274}, must *fire a progress event*^{p53} named *progress*^{p1144} at the *img*^{p272} element.

13. End the *synchronous section*^{p837}, continuing the remaining steps *in parallel*^{p41}, but without missing any data from the *fetch*^{p84} algorithm.
14. As soon as possible, jump to the first applicable entry from the following list:

↪ If the resource type is *multipart/x-mixed-replace*^{p1117}

The next *task*^{p834} that is *queued*^{p835} by the *networking task source*^{p839} while the image is being *fetched*^{p84} must run the following steps:

1. If *image request* is the *pending request*^{p274} and at least one body part has been completely decoded, *abort the image request*^{p278} for the *current request*^{p274}, *upgrade the pending request to the current request*^{p278}.
2. Otherwise, if *image request* is the *pending request*^{p274} and the user agent is able to determine that *image request*'s image is corrupted in some fatal way such that the image dimensions cannot be obtained, *abort the image request*^{p278} for the *current request*^{p274}, *upgrade the pending request to the current request*^{p278} and set the *current request*^{p274}'s state to *broken*^{p274}.
3. Otherwise, if *image request* is the *current request*^{p274}, it is in the *unavailable*^{p274} state, and the user agent is able to determine *image request*'s image's width and height, set the *current request*^{p274}'s state to *partially available*^{p274}.
4. Otherwise, if *image request* is the *current request*^{p274}, it is in the *unavailable*^{p274} state, and the user agent is able to determine that *image request*'s image is corrupted in some fatal way such that the image dimensions cannot be obtained, set the *current request*^{p274}'s state to *broken*^{p274}.

Each *task*^{p834} that is *queued*^{p835} by the *networking task source*^{p839} while the image is being *fetched*^{p84} must update the presentation of the image, but as each new body part comes in, it must replace the previous image. Once one body part has been completely decoded, the user agent must set the *img*^{p272} element to the *completely available*^{p274} state and *queue a task*^{p835} to *fire a simple event*^{p846} named *load*^{p1144} at the *img*^{p272} element.

Note The `progress`^{p1144} and `loadend`^{p1144} events are not fired for `multipart/x-mixed-replace`^{p1117} image streams.

↪ If the resource type and data corresponds to a supported image format, as described below^{p279}

The next `task`^{p834} that is `queued`^{p835} by the `networking task source`^{p839} while the image is being `fetched`^{p84} must run the following steps:

1. If the user agent is able to determine `image request`'s image's width and height, and `image request` is `pending request`^{p274}, set `image request`'s state to `partially available`^{p274}.
2. Otherwise, if the user agent is able to determine `image request`'s image's width and height, and `image request` is `current request`^{p274}, update the `img`^{p272} element's presentation appropriately and set `image request`'s state to `partially available`^{p274}.
3. Otherwise, if the user agent is able to determine that `image request`'s image is corrupted in some fatal way such that the image dimensions cannot be obtained, and `image request` is `pending request`^{p274}, `abort the image request`^{p278} for the `current request`^{p274} and the `pending request`^{p274}, `upgrade the pending request to the current request`^{p278}, set `current request`^{p274} to the `broken`^{p274} state, `fire a simple event`^{p846} named `error`^{p1144} at the `img`^{p272} element, `fire a simple event`^{p846} named `loadend`^{p1144} at the `img`^{p272} element, and abort these steps.
4. Otherwise, if the user agent is able to determine that `image request`'s image is corrupted in some fatal way such that the image dimensions cannot be obtained, and `image request` is `current request`^{p274}, `abort the image request`^{p278} for `image request`, `fire a simple event`^{p846} named `error`^{p1144} at the `img`^{p272} element, `fire a simple event`^{p846} named `loadend`^{p1144} at the `img`^{p272} element, and abort these steps.

That `task`^{p834}, and each subsequent `task`^{p834}, that is `queued`^{p835} by the `networking task source`^{p839} while the image is being `fetched`^{p84}, if `image request` is the `current request`^{p274}, must update the presentation of the image appropriately (e.g. if the image is a progressive JPEG, each packet can improve the resolution of the image).

Spec bugs: 25797, 25798

Furthermore, the last `task`^{p834} that is `queued`^{p835} by the `networking task source`^{p839} once the resource has been `fetched`^{p84} must additionally run these steps:

1. If `image request` is the `pending request`^{p274}, `abort the image request`^{p278} for the `current request`^{p274}, `upgrade the pending request to the current request`^{p278} and update the `img`^{p272} element's presentation appropriately.
2. Set `image request` to the `completely available`^{p274} state.
3. Add the image to the `list of available images`^{p275} using the key `key`, with the `ignore higher-layer caching`^{p275} flag set.
4. `Fire a progress event or simple event`^{p279} named `load`^{p1144} at the `img`^{p272} element, depending on the resource in `image request`.
5. `Fire a progress event or simple event`^{p279} named `loadend`^{p1144} at the `img`^{p272} element, depending on the resource in `image request`.

↪ Otherwise

The image data is not in a supported file format; the user agent must set `image request` to the `broken`^{p274} state, `abort the image request`^{p278} for the `current request`^{p274} and the `pending request`^{p274}, `upgrade the pending request to the current request`^{p278} if `image request` is the `pending request`^{p274}, and then `queue a task`^{p835} to first `fire a simple event`^{p846} named `error`^{p1144} at the `img`^{p272} element and then `fire a simple event`^{p846} named `loadend`^{p1144} at the `img`^{p272} element.

To `abort the image request` for an `image request`^{p274} `image request` means to run the following steps:

1. Forget `image request`'s `image data`^{p274}, if any.
2. Abort any instance of the `fetching`^{p84} algorithm for `image request`, discarding any pending tasks generated by that algorithm.

To `upgrade the pending request to the current request` for an `img`^{p272} element means to run the following steps:

1. Let the `img`^{p272} element's `current request`^{p274} be the `pending request`^{p274}.
2. Let the `img`^{p272} element's `pending request`^{p274} be null.

To fire a progress event or simple event named *type* at an element *e*, depending on resource *r*, means to [fire a progress event^{b53}](#) named *type* at *e* if *r* is [CORS-same-origin^{b87}](#), and otherwise [fire a simple event^{b846}](#) named *type* at *e*.

While a user agent is running the above algorithm for an element *x*, there must be a strong reference from the element's [node document](#) to the element *x*, even if that element is not [in its Document^{p42}](#).

When an [img^{p272}](#) element is in the [completely available^{p274}](#) state and the user agent can decode the media data without errors, then the [img^{p272}](#) element is said to be **fully decodable**.

Whether the image is fetched successfully or not (e.g. whether the response code was a 2xx code [or equivalent^{p83}](#)) must be ignored when determining the image's type and whether it is a valid image.

Note This allows servers to return images with error responses, and have them displayed.

The user agent should apply the [image sniffing rules](#) to determine the type of the image, with the image's [associated Content-Type headers^{b86}](#) giving the **official type**. If these rules are not applied, then the type of the image must be the type given by the image's [associated Content-Type headers^{b86}](#).
Spec bugs: [25889](#) [26702](#) :

User agents must not support non-image resources with the [img^{p272}](#) element (e.g. XML files whose root element is an HTML element). User agents must not run executable code (e.g. scripts) embedded in the image resource. User agents must only display the first page of a multipage resource (e.g. a PDF file). User agents must not allow the resource to act in an interactive fashion, but should honour any animation in the resource.

This specification does not specify which image types are to be supported.

An [img^{p272}](#) element is associated with a [source set^{p279}](#).

A **source set** is an ordered set of zero or more [image sources^{p279}](#) and a [source size^{p279}](#).

An **image source** is a [URL^{p48}](#), and optionally either a density descriptor, or a width descriptor.

A **source size** is a [<source-size-value>^{p274}](#). When a [source size^{p279}](#) has a unit relative to the viewport, it must be interpreted relative to the [img^{p272}](#) element's [node document](#)'s viewport. Other units must be interpreted the same as in Media Queries. [\[MQ\]^{p1151}](#)

A [source size^{p279}](#) must not use CSS functions other than the `calc()` function.

When asked to **select an image source** for a given [img^{p272}](#) element *el*, user agents must do the following:

1. [Update the source set^{p279}](#) for *el*.
2. If *el*'s [source set^{p279}](#) is empty, return null as the URL and undefined as the pixel density and abort these steps.
3. Otherwise, take *el*'s [source set^{p279}](#) and let it be **source set**.
4. If an entry *b* in **source set** has the same associated density descriptor as an earlier entry *a* in **source set**, then remove entry *b*. Repeat this step until none of the entries in **source set** have the same associated density descriptor as an earlier entry.
5. In a user agent-specific manner, choose one [image source^{p279}](#) from **source set**. Let this be **selected source**.
6. Return **selected source** and its associated pixel density.

When asked to **update the source set** for a given [img^{p272}](#) element *el*, user agents must do the following:

1. Set *el*'s [source set^{p279}](#) to an empty [source set^{p279}](#).
2. If *el* has a parent node and that is a [picture^{p270}](#) element, let *elements* be an array containing *el*'s parent node's child elements, retaining relative order. Otherwise, let *elements* be array containing only *el*.
3. Iterate through *elements*, doing the following for each item *child*:
 1. If *child* is *el*:
 1. If *child* has a [srcset^{p273}](#) attribute, [parse child's srcset attribute^{p280}](#) and let the returned [source set^{p279}](#) be **source set**. Otherwise, let **source set** be an empty [source set^{p279}](#).

2. Parse *child's sizes attribute*^{p282} and let *source set's source size*^{p279} be the returned value.
3. If *child* has a *src*^{b273} attribute whose value is not the empty string and *source set* does not contain an *image source*^{p279} with a density descriptor value of 1, and no *image source*^{p279} with a width descriptor, append *child's src*^{b273} attribute value to *source set*.
4. Normalise the source densities^{p283} of *source set*.
5. Let *e*'s *source set*^{p279} be *source set*.
6. Abort this algorithm.

2. If *child* is not a *source*^{p271} element, continue to the next child. Otherwise, *child* is a *source*^{p271} element.
3. If *child* does not have a *srcset*^{p271} attribute, continue to the next child.
4. Parse *child's srcset attribute*^{p280} and let the returned *source set*^{p279} be *source set*.
5. If *source set* has zero *image sources*^{p279}, continue to the next child.
6. If *child* has a *media*^{p271} attribute, and its value does not *match the environment*^{p81}, continue to the next child.
7. Parse *child's sizes attribute*^{p282} and let *source set's source size*^{p279} be the returned value.
8. If *child* has a *type*^{p271} attribute, and its value is an unknown or unsupported *MIME type*^{p42}, continue to the next child.
9. Normalise the source densities^{p283} of *source set*.
10. Let *e*'s *source set*^{p279} be *source set*.
11. Abort this algorithm.

Note Each *img*^{p272} element independently considers its previous sibling *source*^{p271} elements plus the *img*^{p272} element itself for selecting an *image source*^{p279}, ignoring any other (invalid) elements, including other *img*^{p272} elements in the same *picture*^{p270} element, or *source*^{b271} elements that are following siblings of the relevant *img*^{p272} element.

When asked to **parse a srcset attribute** from an element, parse the value of the element's *srcset* attribute as follows:

1. Let *input* be the value passed to this algorithm.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Let *candidates* be an initially empty *source set*^{p279}.
4. *Splitting loop*: Collect a sequence of characters^{p59} that are space characters^{p58} or U+002C COMMA characters. If any U+002C COMMA characters were collected, that is a *parse error*^{p282}.
5. If *position* is past the end of *input*, return *candidates* and abort these steps.
6. Collect a sequence of characters^{p59} that are not space characters^{p58}, and let that be *url*.
7. Let *descriptors* be a new empty list.
8. If *url* ends with a U+002C COMMA character (,), follow these substeps:
 1. Remove all trailing U+002C COMMA characters from *url*. If this removed more than one character, that is a *parse error*^{p282}.

Otherwise, follow these substeps:

1. Descriptor tokeniser: Skip whitespace^{b59}
2. Let *current descriptor* be the empty string.
3. Let *state* be *in descriptor*.
4. Let *c* be the character at *position*. Do the following depending on the value of *state*. For the purpose of this step, "EOF" is a special character representing that *position* is past the end of *input*.

↪ **In descriptor**

Do the following, depending on the value of *c*:

↪ **Space character**^{p58}

If *current descriptor* is not empty, append *current descriptor* to *descriptors* and let *current descriptor* be the empty string. Set *state* to *after descriptor*.

↪ **U+002C COMMA (,)**

Advance *position* to the next character in *input*. If *current descriptor* is not empty, append *current descriptor* to *descriptors*. Jump to the step labeled *descriptor parser*.

↪ **U+0028 LEFT PARENTHESIS ()**

Append *c* to *current descriptor*. Set *state* to *in parens*.

↪ **EOF**

If *current descriptor* is not empty, append *current descriptor* to *descriptors*. Jump to the step labeled *descriptor parser*.

↪ **Anything else**

Append *c* to *current descriptor*.

↪ **In parens**

Do the following, depending on the value of *c*:

↪ **U+0029 RIGHT PARENTHESIS ()**

Append *c* to *current descriptor*. Set *state* to *in descriptor*.

↪ **EOF**

Append *current descriptor* to *descriptors*. Jump to the step labeled *descriptor parser*.

↪ **Anything else**

Append *c* to *current descriptor*.

↪ **After descriptor**

Do the following, depending on the value of *c*:

↪ **Space character**^{p58}

Stay in this state.

↪ **EOF**

Jump to the step labeled *descriptor parser*.

↪ **Anything else**

Set *state* to *in descriptor*. Set *position* to the *previous character* in *input*.

Advance *position* to the next character in *input*. Repeat this substep.

Note *In order to be compatible with future additions, this algorithm supports multiple descriptors and descriptors with parens.*

9. *Descriptor parser*: Let *error* be *no*.
10. Let *width* be *absent*.
11. Let *density* be *absent*.
12. Let *future-compat-h* be *absent*.
13. For each descriptor in *descriptors*, run the appropriate set of steps from the following list:
 - ↪ **If the descriptor consists of a valid non-negative integer**^{p61} followed by a U+0077 LATIN SMALL LETTER W character
 1. If the user agent does not support the *sizes*^{p274} attribute, let *error* be *yes*.

Note A conforming user agent will support the [sizes^{p274}](#) attribute. However, user agents typically implement and ship features in an incremental manner in practice.

2. If *width* and *density* are not both *absent*, then let *error* be *yes*.
3. Apply the [rules for parsing non-negative integers^{p61}](#) to the descriptor. If the result is zero, let *error* be *yes*. Otherwise, let *width* be the result.

↪ If the descriptor consists of a [valid floating-point number^{p61}](#) followed by a U+0078 LATIN SMALL LETTER X character

1. If *width*, *density* and *future-compat-h* are not all *absent*, then let *error* be *yes*.
2. Apply the [rules for parsing floating-point number values^{p62}](#) to the descriptor. If the result is less than zero, let *error* be *yes*. Otherwise, let *density* be the result.

Note If *density* is zero, the intrinsic dimensions will be infinite. User agents are expected to have limits in how big images can be rendered, which is allowed by the [hardware limitations^{p47}](#) clause.

↪ If the descriptor consists of a [valid non-negative integer^{p61}](#) followed by a U+0068 LATIN SMALL LETTER H character

This is a [parse error^{p282}](#).

1. If *future-compat-h* and *density* are not both *absent*, then let *error* be *yes*.
2. Apply the [rules for parsing non-negative integers^{p61}](#) to the descriptor. If the result is zero, let *error* be *yes*. Otherwise, let *future-compat-h* be the result.

↪ Anything else

Let *error* be *yes*.

14. If *future-compat-h* is not *absent* and *width* is *absent*, let *error* be *yes*.
15. If *error* is still *no*, then append a new [image source^{p279}](#) to *candidates* whose URL is *url*, associated with a width *width* if not *absent* and a pixel density *density* if not *absent*. Otherwise, there is a [parse error^{p282}](#).
16. Return to the step labeled *splitting loop*.

When asked to **parse a sizes attribute** from an element, [parse a comma-separated list of component values^{p270}](#) from the value of the element's **sizes** attribute (or the empty string, if the attribute is absent), and let *unparsed sizes list* be the result. [\[CSSSYNTAX\]^{p1149}](#)

For each *unparsed size* in *unparsed sizes list*:

1. Remove all consecutive [`<whitespace-token>`^{p270}](#)'s from the end of *unparsed size*. If *unparsed size* is now empty, that is a [parse error^{p282}](#); continue to the next iteration of this algorithm.
2. If the last [component value^{p270}](#) in *unparsed size* is a valid non-negative [`<source-size-value>`^{p274}](#), let *size* be its value and remove the [component value^{p270}](#) from *unparsed size*. Any CSS function other than the `calc()` function is invalid. Otherwise, there is a [parse error^{p282}](#); continue to the next iteration of this algorithm.
3. Remove all consecutive [`<whitespace-token>`^{p270}](#)'s from the end of *unparsed size*. If *unparsed size* is now empty, return *size* and exit this algorithm. If this was not the last item in *unparsed sizes list*, that is a [parse error^{p282}](#).
4. Parse the remaining [component values^{p270}](#) in *unparsed size* as a [`<media-condition>`^{p270}](#). If it does not parse correctly, or it does parse correctly but the [`<media-condition>`^{p270}](#) evaluates to false, continue to the next iteration of this algorithm. [\[MQI\]^{p1151}](#)
5. Return *size* and exit this algorithm.

If the above algorithm exhausts *unparsed sizes list* without returning a *size* value, return `100vw`.

A **parse error** for the algorithms above indicates a non-fatal mismatch between input and requirements. User agents are encouraged to expose [parse error^{p282}](#) somehow.

Note While a [valid source size list^{p274}](#) only contains a bare [`<source-size-value>`^{p274}](#) (without an accompanying [`<media-condition>`^{p270}](#)) as the last entry in the [`<source-size-list>`^{p274}](#), the parsing algorithm technically allows such at any point in the list, and will accept it immediately as the size if the preceding entries in the list weren't used. This is to enable future extensions, and protect against simple author errors such as a final trailing comma.

An [image source](#)^{p279} can have a density descriptor, a width descriptor, or no descriptor at all accompanying its URL. Normalising a [source set](#)^{p279} gives every [image source](#)^{p279} a density descriptor.

When asked to **normalise the source densities** of a [source set](#)^{p279} source set, the user agent must do the following:

1. Let **source size** be **source set's source size**^{p279}.
2. For each [image source](#)^{p279} in **source set**:
 1. If the [image source](#)^{p279} has a density descriptor, continue to the next [image source](#)^{p279}.
 2. Otherwise, if the [image source](#)^{p279} has a width descriptor, replace the width descriptor with a density descriptor with a value of the width descriptor divided by the [source size](#)^{p279} and a unit of \times .

Note *If the [source size](#)^{p279} is zero, the density would be infinity, which results in the intrinsic dimensions being zero by zero.*
 3. Otherwise, give the [image source](#)^{p279} a density descriptor of 1x .

The user agent may at any time run the following algorithm to update an [img](#)^{p272} element's image in order to react to changes in the environment. (User agents are *not required* to ever run this algorithm; for example, if the user is not looking at the page any more, the user agent might want to wait until the user has returned to the page before determining which image to use, in case the environment changes again in the meantime.)

Note *User agents are encouraged to run this algorithm in particular when the user changes the viewport's size (e.g. by resizing the window or changing the page zoom), and when an [img](#)^{p272} element is inserted into a document, so that the [density-corrected intrinsic width and height](#)^{p275} match the new viewport, and so that the correct image is chosen when [art direction](#)^{p266} is involved.*

1. [Await a stable state](#)^{p837}. The [synchronous section](#)^{p837} consists of all the remaining steps of this algorithm until the algorithm says the [synchronous section](#)^{p837} has ended. (Steps in [synchronous sections](#)^{p837} are marked with \mathbb{X} .)
2. \mathbb{X} If the [img](#)^{p272} element does not have a [srcset](#)^{p273} attribute specified and it either has no parent or it is not a [picture](#)^{p270} element, it is not [in a Document](#)^{p42}, has image data whose resource type is [multipart/x-mixed-replace](#)^{p1117}, or the [pending request](#)^{p274} is not null, then abort this algorithm.
3. \mathbb{X} Let **selected source** and **selected pixel density** be the URL and pixel density that results from [selecting an image source](#)^{p279}, respectively.
4. \mathbb{X} If **selected source** is null, then abort these steps.
5. \mathbb{X} If **selected source** and **selected pixel density** are the same as the element's [last selected source](#)^{p275} and [current pixel density](#)^{p275}, then abort these steps.
6. \mathbb{X} [Resolve](#)^{p82} **selected source**, relative to the element, and let the result be **absolute URL**. If that is not successful, abort these steps.
7. \mathbb{X} Let **CORS mode** be the state of the element's [crossorigin](#)^{p274} content attribute.
8. \mathbb{X} Let **origin** be the [origin](#)^{p776} of the [img](#)^{p272} element's [node document](#).
9. \mathbb{X} Let **key** be a tuple consisting of **absolute URL**, **CORS mode**, and, if **CORS mode** is not [No CORS](#)^{p87}, **origin**.
10. \mathbb{X} Let **image request** be a new [image request](#)^{p274} whose [current URL](#)^{p274} is **absolute URL**.
11. \mathbb{X} Let the element's [pending request](#)^{p274} be **image request**.
12. End the [synchronous section](#)^{p837}, continuing the remaining steps [in parallel](#)^{p41}.
13. If the [list of available images](#)^{p275} contains an entry for **key**, then set **image request's image data**^{p274} to that of the entry. Continue to the next step.

Otherwise, do a [potentially CORS-enabled fetch](#)^{p87} of **absolute URL**, with the **mode** being **CORS mode**, the **origin** being **origin**, and the **default origin behaviour** set to **taint**.

If this download fails in any way (other than the response code not being a 2xx code, as mentioned earlier), or if the image format is unsupported (as determined by applying the [image sniffing rules](#), again as mentioned earlier), or if the user agent is able to determine that **image request's** image is corrupted in some fatal way such that the image dimensions cannot be obtained, or if the resource type is [multipart/x-mixed-replace](#)^{p1117}, then let [pending request](#)^{p274} be null and abort these steps.

Otherwise, wait for the `fetch`^{p84} algorithm to queue its last task, and then continue with these steps. The resource obtained in this fashion, if any, is *image request's image data*^{p274}. It can be either `CORS-same-origin`^{p87} or `CORS-cross-origin`^{p87}; this affects the `origin`^{p776} of the image itself (e.g. when used on a `canvas`^{b607}).

14. Queue a task^{p835} to run the following substeps:

1. If the `img`^{p272} element has experienced `relevant mutations`^{p275} since this algorithm started, then let `pending request`^{p274} be null and abort these steps.
2. Let the `img`^{p272} element's `last selected source`^{p275} be `selected source` and the `img`^{p272} element's `current pixel density`^{b275} be `selected pixel density`.
3. Set *image request* to the `completely available`^{p274} state.
4. Add the image to the `list of available images`^{p275} using the key `key`, with the `ignore higher-layer caching`^{p275} flag set.
5. Upgrade the pending request to the current request^{p278}.
6. Update the `img`^{p272} element's presentation appropriately.
7. Fire a simple event^{p846} named `load`^{p1144} at the `img`^{p272} element.

The `task source`^{p835} for the `tasks`^{p834} `queued`^{p835} by algorithms in this section is the `DOM manipulation task source`^{p838}.

What an `img`^{p272} element represents depends on the `src`^{p273} attribute and the `alt`^{p273} attribute.

↪ **If the `src`^{p273} attribute is set and the `alt`^{p273} attribute is set to the empty string**

The image is either decorative or supplemental to the rest of the content, redundant with some other information in the document.

If the image is `available`^{p274} and the user agent is configured to display that image, then the element `represents`^{p111} the element's image data.

Otherwise, the element `represents`^{p111} nothing, and may be omitted completely from the rendering. User agents may provide the user with a notification that an image is present but has been omitted from the rendering.

↪ **If the `src`^{p273} attribute is set and the `alt`^{p273} attribute is set to a value that isn't empty**

The image is a key part of the content; the `alt`^{p273} attribute gives a textual equivalent or replacement for the image.

If the image is `available`^{p274} and the user agent is configured to display that image, then the element `represents`^{p111} the element's image data.

Otherwise, the element `represents`^{p111} the text given by the `alt`^{p273} attribute. User agents may provide the user with a notification that an image is present but has been omitted from the rendering.

↪ **If the `src`^{p273} attribute is set and the `alt`^{p273} attribute is not**

The image might be a key part of the content, and there is no textual equivalent of the image available.

Note *In a conforming document, the absence of the `alt`^{p273} attribute indicates that the image is a key part of the content but that a textual replacement for the image was not available when the image was generated.*

If the image is `available`^{p274} and the user agent is configured to display that image, then the element `represents`^{p111} the element's image data.

Otherwise, the user agent should display some sort of indicator that there is an image that is not being rendered, and may, if requested by the user, or if so configured, or when required to provide contextual information in response to navigation, provide caption information for the image, derived as follows:

1. If the image has a `title`^{p122} attribute whose value is not the empty string, then the value of that attribute is the caption information; abort these steps.

2. If the image is a descendant of a [figure](#)^{p202} element that has a child [figcaption](#)^{p205} element, and, ignoring the [figcaption](#)^{p205} element and its descendants, the [figure](#)^{p202} element has no [flow content](#)^{p115} descendants other than [inter-element whitespace](#)^{p113} and the [img](#)^{p272} element, then the contents of the first such [figcaption](#)^{p205} element are the caption information; abort these steps.

3. There is no caption information.

↪ If the [src](#)^{p273} attribute is not set and either the [alt](#)^{p273} attribute is set to the empty string or the [alt](#)^{p273} attribute is not set at all
The element [represents](#)^{p111} nothing.

↪ Otherwise

The element [represents](#)^{p111} the text given by the [alt](#)^{p273} attribute.

The [alt](#)^{p273} attribute does not represent advisory information. User agents must not present the contents of the [alt](#)^{p273} attribute in the same way as content of the [title](#)^{p122} attribute.

User agents may always provide the user with the option to display any image, or to prevent any image from being displayed. User agents may also apply heuristics to help the user make use of the image when the user is unable to see it, e.g. due to a visual disability or because they are using a text terminal with no graphics capabilities. Such heuristics could include, for instance, optical character recognition (OCR) of text found within the image.

⚠ Warning! While user agents are encouraged to repair cases of missing [alt](#)^{p273} attributes, authors must not rely on such behaviour. Requirements for providing text to act as an alternative for images^{p288} are described in detail below.

The *contents* of [img](#)^{p272} elements, if any, are ignored for the purposes of rendering.

The [usemap](#)^{b393} attribute, if present, can indicate that the image has an associated [image map](#)^{b393}.

The [ismap](#) attribute, when used on an element that is a descendant of an [a](#)^{p208} element with an [href](#)^{b245} attribute, indicates by its presence that the element provides access to a server-side image map. This affects how events are handled on the corresponding [a](#)^{p208} element.

The [ismap](#)^{p285} attribute is a [boolean attribute](#)^{b59}. The attribute must not be specified on an element that does not have an ancestor [a](#)^{p208} element with an [href](#)^{p245} attribute.

Note The [usemap](#)^{b393} and [ismap](#)^{p285} attributes can result in confusing behaviour when used together with [source](#)^{p271} elements with the [media](#)^{p271} attribute specified in a [picture](#)^{p270} element.

The [img](#)^{p272} element supports [dimension attributes](#)^{p397}.

The [alt](#), [src](#), [srcset](#) and [sizes](#) IDL attributes must [reflect](#)^{p88} the respective content attributes of the same name.

The [crossOrigin](#) IDL attribute must [reflect](#)^{p88} the [crossorigin](#)^{p274} content attribute.

The [useMap](#) IDL attribute must [reflect](#)^{p88} the [usemap](#)^{b393} content attribute.

The [isMap](#) IDL attribute must [reflect](#)^{p88} the [ismap](#)^{p285} content attribute.

Note

`image.widthp286 [= value]`
`image.heightp286 [= value]`

These attributes return the actual rendered dimensions of the image, or zero if the dimensions are not known.

They can be set, to change the corresponding content attributes.

`image.naturalWidthp286`
`image.naturalHeightp286`

These attributes return the intrinsic dimensions of the image, or zero if the dimensions are not known.

`image.completep286`

Returns true if the image has been completely downloaded or if no image is specified; otherwise, returns false.

`image.currentSrcp286`

Returns the image's [absolute URL^{p48}](#).

`image = new Imagep286([width [, height]])`

Returns a new `imgp272` element, with the `widthp397` and `heightp397` attributes set to the values passed in the relevant arguments, if applicable.

The IDL attributes `width` and `height` must return the rendered width and height of the image, in CSS pixels, if the image is [being rendered^{p1058}](#), and is being rendered to a visual medium; or else the [density-corrected intrinsic width and height^{p275}](#) of the image, in CSS pixels, if the image has intrinsic dimensions and is [available^{p274}](#) but not being rendered to a visual medium; or else 0, if the image is not [available^{p274}](#) or does not have intrinsic dimensions. [\[CSS\]^{p1149}](#)

On setting, they must act as if they [reflected^{p88}](#) the respective content attributes of the same name.

The IDL attributes `naturalWidth` and `naturalHeight` must return the [density-corrected intrinsic width and height^{p275}](#) of the image, in CSS pixels, if the image has intrinsic dimensions and is [available^{p274}](#), or else 0. [\[CSS\]^{p1149}](#)

Spec bugs: [23581](#)

The IDL attribute `complete` must return true if any of the following conditions is true:

Spec bugs: [18742](#), [26113](#)

- Both the `srcp273` attribute and the `srcsetp273` attribute are omitted.
- The `srcsetp273` attribute is omitted and the `srcp273` attribute's value is the empty string.
- The final `taskp834` that is [queued^{p835}](#) by the [networking task source^{p839}](#) once the resource has been [fetched^{p84}](#) has been [queued^{p835}](#).
- The `imgp272` element is [completely available^{p274}](#).
- The `imgp272` element is [broken^{p274}](#).

Otherwise, the attribute must return false.

Note The value of `completep286` can thus change while a `scriptp828` is executing.

The `currentSrc` IDL attribute must return the `imgp272` element's [current request^{p274}](#)'s [current URL^{p274}](#).

A constructor is provided for creating `HTMLImageElementp272` objects (in addition to the factory methods from DOM such as `createElement()`): `Image(width, height)`. When invoked as a constructor, this must return a new `HTMLImageElementp272` object (a new `imgp272` element). If the `width` argument is present, the new object's `widthp397` content attribute must be set to `width`. If the `height` argument is also present, the new object's `heightp397` content attribute must be set to `height`. The element's `node document` must be the [active document^{p762}](#) of the [browsing context^{p762}](#) of the `Windowp768` object on which the interface object of the invoked constructor is found.

Example

A single image can have different appropriate alternative text depending on the context.

In each of the following cases, the same image is used, yet the `altp273` text is different each time. The image is the coat of arms of the Carouge municipality in the canton Geneva in Switzerland.

Here it is used as a supplementary icon:

```
<p>I lived in  Carouge.</p>
```

Here it is used as an icon representing the town:

```
<p>Home town: </p>
```

Here it is used as part of a text on the town:

```

<p>Carouge has a coat of arms.</p>
<p></p>
<p>It is used as decoration all over the town.</p>

```

Here it is used as a way to support a similar text where the description is given as well as, instead of as an alternative to, the image:

```

<p>Carouge has a coat of arms.</p>
<p></p>
<p>The coat of arms depicts a lion, sitting in front of a tree.
It is used as decoration all over the town.</p>

```

Here it is used as part of a story:

```

<p>He picked up the folder and a piece of paper fell out.</p>
<p></p>
<p>He stared at the folder. S! The answer he had been looking for all this time was simply the letter S! How had he not seen that before? It all came together now. The phone call where Hector had referred to a lion's tail, the time Marco had stuck his tongue out...</p>

```

Here it is not known at the time of publication what the image will be, only that it will be a coat of arms of some kind, and thus no replacement text can be provided, and instead only a brief caption for the image is provided, in the title^{b122} attribute:

```

<p>The last user to have uploaded a coat of arms uploaded this one:</p>
<p></p>

```

Ideally, the author would find a way to provide real replacement text even in this case, e.g. by asking the previous user. Not providing replacement text makes the document more difficult to use for people who are unable to view images, e.g. blind users, or users or very low-bandwidth connections or who pay by the byte, or users who are forced to use a text-only Web browser.

Example

Here are some more examples showing the same picture used in different contexts, with different appropriate alternate texts each time.

```

<article>
<h1>My cats</h1>
<h2>Fluffy</h2>
<p>Fluffy is my favourite.</p>

<p>She's just too cute.</p>
<h2>Miles</h2>
<p>My other cat, Miles just eats and sleeps.</p>
</article>

<article>
<h1>Photography</h1>
<h2>Shooting moving targets indoors</h2>
<p>The trick here is to know how to anticipate; to know at what speed and what distance the subject will pass by.</p>

<h2>Nature by night</h2>
<p>To achieve this, you'll need either an extremely sensitive film, or immense flash lights.</p>
</article>

<article>
<h1>About me</h1>
<h2>My pets</h2>
<p>I've got a cat named Fluffy and a dog named Miles.</p>

<p>My dog Miles and I like go on long walks together.</p>

```

```

<h2>music</h2>
<p>After our walks, having emptied my mind, I like listening to Bach.</p>
</article>

<article>
<h1>Fluffy and the Yarn</h1>
<p>Fluffy was a cat who liked to play with yarn. He also liked to jump.</p>
<aside></aside>
<p>He would play in the morning, he would play in the evening.</p>
</article>

```

4.8.5.1 Requirements for providing text to act as an alternative for images

4.8.5.1.1 General guidelines

Except where otherwise specified, the `altp273` attribute must be specified and its value must not be empty; the value must be an appropriate replacement for the image. The specific requirements for the `altp273` attribute depend on what the image is intended to represent, as described in the following sections.

The most general rule to consider when writing alternative text is the following: **the intent is that replacing every image with the text of its `altp273` attribute not change the meaning of the page.**

So, in general, alternative text can be written by considering what one would have written had one not been able to include the image.

A corollary to this is that the `altp273` attribute's value should never contain text that could be considered the image's *caption*, *title*, or *legend*. It is supposed to contain replacement text that could be used by users *instead* of the image; it is not meant to supplement the image. The `titlep122` attribute can be used for supplemental information.

Another corollary is that the `altp273` attribute's value should not repeat information that is already provided in the prose next to the image.

Note One way to think of alternative text is to think about how you would read the page containing the image to someone over the phone, without mentioning that there is an image present. Whatever you say instead of the image is typically a good start for writing the alternative text.

4.8.5.1.2 A link or button containing nothing but the image

Spec bugs: [16125](#)

When an `ap208` element that creates a `hyperlinkp245`, or a `buttonp495` element, has no textual content but contains one or more images, the `altp273` attributes must contain text that together convey the purpose of the link or button.

Example

In this example, a user is asked to pick his preferred colour from a list of three. Each colour is given by an image, but for users who have configured their user agent not to display images, the colour names are used instead:

```

<h1>Pick your colour</h1>
<ul>
  <li><a href="green.html"></a></li>
  <li><a href="blue.html"></a></li>
  <li><a href="red.html"></a></li>
</ul>

```

Example

In this example, each button has a set of images to indicate the kind of colour output desired by the user. The first image is used in each case to give the alternative text.

```

<button name="rgb"></button>
<button name="cmyk"></button>

```

Since each image represents one part of the text, it could also be written like this:

```
<button name="rgb"></button>
<button name="cmyk"></button>
```

However, with other alternative text, this might not work, and putting all the alternative text into one image in each case might make more sense:

```
<button name="rgb"></button>
<button name="cmyk"></button>
```

4.8.5.1.3 A phrase or paragraph with an alternative graphical representation: charts, diagrams, graphs, maps, illustrations

Sometimes something can be more clearly stated in graphical form, for example as a flowchart, a diagram, a graph, or a simple map showing directions. In such cases, an image can be given using the [img^{p272}](#) element, but the lesser textual version must still be given, so that users who are unable to view the image (e.g. because they have a very slow connection, or because they are using a text-only browser, or because they are listening to the page being read out by a hands-free automobile voice Web browser, or simply because they are blind) are still able to understand the message being conveyed.

The text must be given in the [alt^{p273}](#) attribute, and must convey the same message as the image specified in the [src^{p273}](#) attribute.

It is important to realise that the alternative text is a *replacement* for the image, not a description of the image.

Example

In the following example we have [a flowchart](#) in image form, with text in the [alt^{p273}](#) attribute rephrasing the flowchart in prose form:

```
<p>In the common case, the data handled by the tokenization stage comes from the network, but it can also come from script.</p>
<p></p>
```

Example

Here's another example, showing a good solution and a bad solution to the problem of including an image in a description.

First, here's the good solution. This sample shows how the alternative text should just be what you would have put in the prose if the image had never existed.

```
<!-- This is the correct way to do things. -->
<p>
  You are standing in an open field west of a house.
  
  There is a small mailbox here.
</p>
```

Second, here's the bad solution. In this incorrect way of doing things, the alternative text is simply a description of the image, instead of a textual replacement for the image. It's bad because when the image isn't shown, the text doesn't flow as well as in the first example.

```
<!-- This is the wrong way to do things. -->
<p>
  You are standing in an open field west of a house.
  
  There is a small mailbox here.
</p>
```

Text such as "Photo of white house with boarded door" would be equally bad alternative text (though it could be suitable for the [title^{p122}](#) attribute or in the [figcaption^{p205}](#) element of a [figure^{p202}](#) with this image).

4.8.5.1.4 A short phrase or label with an alternative graphical representation: icons, logos

A document can contain information in iconic form. The icon is intended to help users of visual browsers to recognise features at a glance.

In some cases, the icon is supplemental to a text label conveying the same meaning. In those cases, the [alt^{p273}](#) attribute must be present but must be empty.

Example

Here the icons are next to text that conveys the same meaning, so they have an empty [alt^{p273}](#) attribute:

```
<nav>
  <p><a href="/help/"> Help</a></p>
  <p><a href="/configure/">
    Configuration Tools</a></p>
</nav>
```

In other cases, the icon has no text next to it describing what it means; the icon is supposed to be self-explanatory. In those cases, an equivalent textual label must be given in the [alt^{p273}](#) attribute.

Example

Here, posts on a news site are labeled with an icon indicating their topic.

```
<body>
  <article>
    <header>
      <h1>Ratatouille wins <i>Best Movie of the Year</i> award</h1>
      <p></p>
    </header>
    <p>Pixar has won yet another <i>Best Movie of the Year</i> award,
    making this its 8th win in the last 12 years.</p>
  </article>
  <article>
    <header>
      <h1>Latest TWiT episode is online</h1>
      <p></p>
    </header>
    <p>The latest TWiT episode has been posted, in which we hear
    several tech news stories as well as learning much more about the
    iPhone. This week, the panelists compare how reflective their
    iPhones' Apple logos are.</p>
  </article>
</body>
```

Many pages include logos, insignia, flags, or emblems, which stand for a particular entity such as a company, organization, project, band, software package, country, or some such.

If the logo is being used to represent the entity, e.g. as a page heading, the [alt^{p273}](#) attribute must contain the name of the entity being represented by the logo. The [alt^{p273}](#) attribute must *not* contain text like the word "logo", as it is not the fact that it is a logo that is being conveyed, it's the entity itself.

If the logo is being used next to the name of the entity that it represents, then the logo is supplemental, and its [alt^{p273}](#) attribute must instead be empty.

If the logo is merely used as decorative material (as branding, or, for example, as a side image in an article that mentions the entity to which the logo belongs), then the entry below on purely decorative images applies. If the logo is actually being discussed, then it is being used as a phrase or paragraph (the description of the logo) with an alternative graphical representation (the logo itself), and the first entry above applies.

Example

In the following snippets, all four of the above cases are present. First, we see a logo used to represent a company:

```
<h1></h1>
```

Next, we see a paragraph which uses a logo right next to the company name, and so doesn't have any alternative text:

```
<article>
  <h2>News</h2>
  <p>We have recently been looking at buying the  ABG company, a small Greek company
    specializing in our type of product.</p>
```

In this third snippet, we have a logo being used in an aside, as part of the larger article discussing the acquisition:

```
<aside><p></p></aside>
<p>The ABG company has had a good quarter, and our
  pie chart studies of their accounts suggest a much bigger blue slice
  than its green and orange slices, which is always a good sign.</p>
</article>
```

Finally, we have an opinion piece talking about a logo, and the logo is therefore described in detail in the alternative text.

```
<p>Consider for a moment their logo:</p>

<p></p>

<p>How unoriginal can you get? I mean, ooooh, a question mark, how
  <em>revolutionary</em>, how utterly <em>ground-breaking</em>, I'm
  sure everyone will rush to adopt those specifications now! They could
  at least have tried for some sort of, I don't know, sequence of
  rounded squares with varying shades of green and bold white outlines,
  at least that would look good on the cover of a blue book.</p>
```

This example shows how the alternative text should be written such that if the image isn't [available](#)^{b274}, and the text is used instead, the text flows seamlessly into the surrounding text, as if the image had never been there in the first place.

4.8.5.1.5 Text that has been rendered to a graphic for typographical effect

Sometimes, an image just consists of text, and the purpose of the image is not to highlight the actual typographic effects used to render the text, but just to convey the text itself.

In such cases, the [alt](#)^{b273} attribute must be present but must consist of the same text as written in the image itself.

Example

Consider a graphic containing the text "Earth Day", but with the letters all decorated with flowers and plants. If the text is merely being used as a heading, to spice up the page for graphical users, then the correct alternative text is just the same text "Earth Day", and no mention need be made of the decorations:

```
<h1></h1>
```

Example

An illuminated manuscript might use graphics for some of its images. The alternative text in such a situation is just the character that the image represents.

```
<p>nce upon a time and a long long time ago, late at
  night, when it was dark, over the hills, through the woods, across a great ocean, in a land far
  away, in a small house, on a hill, under a full moon...
```

When an image is used to represent a character that cannot otherwise be represented in Unicode, for example gaiji, itaiji, or new characters such as novel currency symbols, the alternative text should be a more conventional way of writing the same thing, e.g. using the phonetic hiragana or katakana to give the character's pronunciation.

Example

In this example from 1997, a new-fangled currency symbol that looks like a curly E with two bars in the middle instead of one is represented using an image. The alternative text gives the character's pronunciation.

```
<p>Only 5.99!
```

An image should not be used if Unicode characters would serve an identical purpose. Only when the text cannot be directly represented using Unicode, e.g. because of decorations or because the character is not in the Unicode character set (as in the case of gaiji), would an image be appropriate.

Note *If an author is tempted to use an image because their default system font does not support a given character, then Web Fonts are a better solution than images.*

4.8.5.1.6 A graphical representation of some of the surrounding text

In many cases, the image is actually just supplementary, and its presence merely reinforces the surrounding text. In these cases, the [alt^{p273}](#) attribute must be present but its value must be the empty string.

In general, an image falls into this category if removing the image doesn't make the page any less useful, but including the image makes it a lot easier for users of visual browsers to understand the concept.

Example

A flowchart that repeats the previous paragraph in graphical form:

```
<p>The Network passes data to the Input Stream Preprocessor, which  
passes it to the Tokenizer, which passes it to the Tree Construction  
stage. From there, data goes to both the DOM and to Script Execution.  
Script Execution is linked to the DOM, and, using document.write(),  
passes data to the Tokenizer.</p>  
<p></p>
```

In these cases, it would be wrong to include alternative text that consists of just a caption. If a caption is to be included, then either the [title^{p122}](#) attribute can be used, or the [figure^{p202}](#) and [figcaption^{p205}](#) elements can be used. In the latter case, the image would in fact be a phrase or paragraph with an alternative graphical representation, and would thus require alternative text.

```
<!-- Using the title="" attribute -->  
<p>The Network passes data to the Input Stream Preprocessor, which  
passes it to the Tokenizer, which passes it to the Tree Construction  
stage. From there, data goes to both the DOM and to Script Execution.  
Script Execution is linked to the DOM, and, using document.write(),  
passes data to the Tokenizer.</p>  
<p></p>  
  
<!-- Using <figure> and <figcaption> -->  
<p>The Network passes data to the Input Stream Preprocessor, which  
passes it to the Tokenizer, which passes it to the Tree Construction  
stage. From there, data goes to both the DOM and to Script Execution.  
Script Execution is linked to the DOM, and, using document.write(),  
passes data to the Tokenizer.</p>  
<figure>  
  

```

<figcaption>Flowchart representation of the parsing model.</figcaption>
</figure>

<!-- This is WRONG. Do not do this. Instead, do what the above examples do. -->
<p>The Network passes data to the Input Stream Preprocessor, which
passes it to the Tokenizer, which passes it to the Tree Construction
stage. From there, data goes to both the DOM and to Script Execution.
Script Execution is linked to the DOM, and, using document.write(),
passes data to the Tokenizer.</p>
<p></p>
<!-- Never put the image's caption in the alt="" attribute! -->

```

### Example

A graph that repeats the previous paragraph in graphical form:

```

<p>According to a study covering several billion pages,
about 62% of documents on the Web in 2007 triggered the Quirks
rendering mode of Web browsers, about 30% triggered the Almost
Standards mode, and about 9% triggered the Standards mode.</p>
<p></p>

```

#### 4.8.5.1.7 Ancillary images

Sometimes, an image is not critical to the content, but is nonetheless neither purely decorative nor entirely redundant with the text. In these cases, the [alt<sup>p273</sup>](#) attribute must be present, and its value should either be the empty string, or a textual representation of the information that the image conveys. If the image has a caption giving the image's title, then the [alt<sup>p273</sup>](#) attribute's value must not be empty (as that would be quite confusing for non-visual readers).

### Example

Consider a news article about a political figure, in which the individual's face was shown in an image that, through a style sheet, is floated to the right. The image is not purely decorative, as it is relevant to the story. The image is not entirely redundant with the story either, as it shows what the politician looks like. Whether any alternative text need be provided is an authoring decision, in part influenced by whether the image colours the interpretation of the prose.

In this first variant, the image is shown without context, and no alternative text is provided:

```

<p> Ahead of today's referendum,
the First Minister of Scotland, Alex Salmond, wrote an open letter to all
registered voters. In it, he admitted that all countries make mistakes.</p>

```

If the picture is just a face, there might be no value in describing it. It's of no interest to the reader whether the individual has red hair or blond hair, whether the individual has white skin or black skin, whether the individual has one eye or two eyes.

However, if the picture is more dynamic, for instance showing the politician as angry, or particularly happy, or devastated, some alternative text would be useful in setting the tone of the article, a tone that might otherwise be missed:

```

<p>
Ahead of today's referendum, the First Minister of Scotland, Alex Salmond,
wrote an open letter to all registered voters. In it, he admitted that all
countries make mistakes.</p>

<p>
Ahead of today's referendum, the First Minister of Scotland, Alex Salmond,
wrote an open letter to all registered voters. In it, he admitted that all
countries make mistakes.</p>

```

Whether the individual was "sad" or "ecstatic" makes a difference to how the rest of the paragraph is to be interpreted: is he likely saying that he is resigned to the populace making a bad choice in the upcoming referendum, or is he saying that the election was a mistake but the likely turnout will make it irrelevant? The interpretation varies based on the image.

### Example

If the image has a caption, then including alternative text avoids leaving the non-visual user confused as to what the caption refers to.

```
<p>Ahead of today's referendum, the First Minister of Scotland, Alex Salmond,
wrote an open letter to all registered voters. In it, he admitted that all
countries make mistakes.</p>
<figure>

 <figcaption> Alex Salmond, SNP. Photo © 2014 PolitiPhoto. </figcaption>
</figure>
```

#### 4.8.5.1.8 A purely decorative image that doesn't add any information

If an image is decorative but isn't especially page-specific — for example an image that forms part of a site-wide design scheme — the image should be specified in the site's CSS, not in the markup of the document.

However, a decorative image that isn't discussed by the surrounding text but still has some relevance can be included in a page using the `imgp272` element. Such images are decorative, but still form part of the content. In these cases, the `altp273` attribute must be present but its value must be the empty string.

##### Example

Examples where the image is purely decorative despite being relevant would include things like a photo of the Black Rock City landscape in a blog post about an event at Burning Man, or an image of a painting inspired by a poem, on a page reciting that poem. The following snippet shows an example of the latter case (only the first verse is included in this snippet):

```
<h1>The Lady of Shalott</h1>
<p></p>
<p>On either side the river lie

Long fields of barley and of rye,

That clothe the wold and meet the sky;

And through the field the road run by

To many-tower'd Camelot;

And up and down the people go,

Gazing where the lilies blow

Round an island there below,

The island of Shalott.</p>
```

Spec bugs: [24335](#)

#### 4.8.5.1.9 A group of images that form a single larger picture with no links

When a picture has been sliced into smaller image files that are then displayed together to form the complete picture again, one of the images must have its `altp273` attribute set as per the relevant rules that would be appropriate for the picture as a whole, and then all the remaining images must have their `altp273` attribute set to the empty string.

##### Example

In the following example, a picture representing a company logo for XYZ Corp has been split into two pieces, the first containing the letters "XYZ" and the second with the word "Corp". The alternative text ("XYZ Corp") is all in the first image.

```
<h1></h1>
```

##### Example

In the following example, a rating is shown as three filled stars and two empty stars. While the alternative text could have been "★★★☆☆", the author has instead decided to more helpfully give the rating in the form "3 out of 5". That is the alternative text of the first image, and the rest have blank alternative text.

```
<p>Rating: <meter max=5 value=3>
 ></meter></p>
```

#### 4.8.5.1.10 A group of images that form a single larger picture with links

Generally, [image maps](#) should be used instead of slicing an image for links.

However, if an image is indeed sliced and any of the components of the sliced picture are the sole contents of links, then one image per link must have alternative text in its [alt](#) attribute representing the purpose of the link.

##### Example

In the following example, a picture representing the flying spaghetti monster emblem, with each of the left noodly appendages and the right noodly appendages in different images, so that the user can pick the left side or the right side in an adventure.

```
<h1>The Church</h1>
<p>You come across a flying spaghetti monster. Which side of His
Noodliness do you wish to reach out for?</p>
<p>

 </p>
```

#### 4.8.5.1.11 A key part of the content

In some cases, the image is a critical part of the content. This could be the case, for instance, on a page that is part of a photo gallery. The image is the whole *point* of the page containing it.

How to provide alternative text for an image that is a key part of the content depends on the image's provenance.

##### The general case

When it is possible for detailed alternative text to be provided, for example if the image is part of a series of screenshots in a magazine review, or part of a comic strip, or is a photograph in a blog entry about that photograph, text that can serve as a substitute for the image must be given as the contents of the [alt](#) attribute.

**Example** A screenshot in a gallery of screenshots for a new OS, with some alternative text:

```
<figure>

 <figcaption>Screenshot of a KDE desktop.</figcaption>
</figure>
```

**Example** A graph in a financial report:

```

```

Note that "sales graph" would be inadequate alternative text for a sales graph. Text that would be a good *caption* is not generally suitable as replacement text.

#### Images that defy a complete description

In certain cases, the nature of the image might be such that providing thorough alternative text is impractical. For example, the image could be indistinct, or could be a complex fractal, or could be a detailed topographical map.

In these cases, the [alt](#) attribute must contain some suitable alternative text, but it may be somewhat brief.

**Example**

Sometimes there simply is no text that can do justice to an image. For example, there is little that can be said to usefully describe a Rorschach inkblot test. However, a description, even if brief, is still better than nothing:

```
<figure>

 <figcaption>A black outline of the first of the ten cards
 in the Rorschach inkblot test.</figcaption>
</figure>
```

Note that the following would be a very bad use of alternative text:

```
<!-- This example is wrong. Do not copy it. -->
<figure>

 <figcaption>A black outline of the first of the ten cards
 in the Rorschach inkblot test.</figcaption>
</figure>
```

Including the caption in the alternative text like this isn't useful because it effectively duplicates the caption for users who don't have images, taunting them twice yet not helping them any more than if they had only read or heard the caption once.

**Example** Another example of an image that defies full description is a fractal, which, by definition, is infinite in detail.

The following example shows one possible way of providing alternative text for the full view of an image of the Mandelbrot set.

```

```

**Example** Similarly, a photograph of a person's face, for example in a biography, can be considered quite relevant and key to the content, but it can be hard to fully substitute text for

```
<section class="bio">
 <h1>A Biography of Isaac Asimov</h1>
 <p>Born Isaac Yudovich Ozimov in 1920, Isaac was a prolific author.</p>
 <p>
 <p>Asimov was born in Russia, and moved to the US when he was three years old.</p>
 <p>...
 </section>
```

In such cases it is unnecessary (and indeed discouraged) to include a reference to the presence of the image itself in the alternative text, since such text would be redundant with the browser itself reporting the presence of the image. For example, if the alternative text was "A photo of Isaac Asimov", then a conforming user agent might read that out as "(Image) A photo of Isaac Asimov" rather than the more useful "(Image) Isaac Asimov had dark hair, a tall forehead, and wore glasses...".

## Images whose contents are not known

In some unfortunate cases, there might be no alternative text available at all, either because the image is obtained in some automated fashion without any associated alternative text (e.g. a Webcam), or because the page is being generated by a script using user-provided images where the user did not provide suitable or usable alternative text (e.g. photograph sharing sites), or because the author does not himself know what the images represent (e.g. a blind photographer sharing an image on his blog).

In such cases, the [alt](#)<sup>p273</sup> attribute may be omitted, but one of the following conditions must be met as well:

- The `img`<sup>p272</sup> element is in a `figure`<sup>p202</sup> element that contains a `figcaption`<sup>p205</sup> element that contains content other than `inter-element whitespace`<sup>p113</sup>, and, ignoring the `figcaption`<sup>p205</sup> element and its descendants, the `figure`<sup>p202</sup> element has no `flow content`<sup>p115</sup> descendants other than `inter-element whitespace`<sup>p113</sup> and the `img`<sup>p272</sup> element.
- The `title`<sup>p122</sup> attribute is present and has a non-empty value.

**Note** *Relying on the `title`<sup>p122</sup> attribute is currently discouraged as many user agents do not expose the attribute in an accessible manner as required by this specification (e.g. requiring a pointing device such as a mouse to cause a tooltip to appear, which excludes keyboard-only users and touch-only users, such as anyone with a modern phone or tablet).*

**Note** *Such cases are to be kept to an absolute minimum. If there is even the slightest possibility of the author having the ability to provide real alternative text, then it would not be acceptable to omit the `alt`<sup>p273</sup> attribute.*

**Example** A photo on a photo-sharing site, if the site received the image with no metadata other than the caption, could be marked up as follows:

```
<figure>

 <figcaption>Bubbles traveled everywhere with us.</figcaption>
</figure>
```

It would be better, however, if a detailed description of the important parts of the image obtained from the user and included on the page.

**Example** A blind user's blog in which a photo taken by the user is shown. Initially, the user might not have any idea what the photo he took shows:

```
<article>
 <h1>I took a photo</h1>
 <p>I went out today and took a photo!</p>
 <figure>

 <figcaption>A photograph taken blindly from my front porch.</figcaption>
 </figure>
</article>
```

Eventually though, the user might obtain a description of the image from his friends and could then include alternative text:

```
<article>
 <h1>I took a photo</h1>
 <p>I went out today and took a photo!</p>
 <figure>

 <figcaption>A photograph taken blindly from my front porch.</figcaption>
 </figure>
</article>
```

**Example** Sometimes the entire point of the image is that a textual description is not available, and the user is to provide the description. For instance, the point of a CAPTCHA image is to see if the user can literally read the graphic. Here is one way to mark up a CAPTCHA (note the `title`<sup>p122</sup> attribute):

```
<p><label>What does this image say?

 <input type="text" name="captcha"></label>
 (If you cannot see the image, you can use an audio test instead.)</p>
```

Another example would be software that displays images and asks for alternative text precisely for the purpose of then writing a page with correct alternative text. Such a page could have a table of images, like this:

```
<table>
<thead>
 <tr> <th> Image <th> Description
<tbody>
 <tr>
 <td>
 <td> <input name="alt2421">
 <tr>
 <td>
 <td> <input name="alt2422">
</table>
```

Notice that even in this example, as much useful information as possible is still included in the [title<sup>p122</sup>](#) attribute.

**Note** Since some users cannot use images at all (e.g. because they have a very slow connection, or because they are using a text-only browser, or because they are listening to the page being read out by a hands-free automobile voice Web browser, or simply because they are blind), the [alt<sup>p273</sup>](#) attribute is only allowed to be omitted rather than being provided with replacement text when no alternative text is available and none can be made available, as in the above examples. Lack of effort from the part of the author is not an acceptable reason for omitting the [alt<sup>p273</sup>](#) attribute.

#### 4.8.5.1.12 An image not intended for the user

Generally authors should avoid using [img<sup>p272</sup>](#) elements for purposes other than showing images.

If an [img<sup>p272</sup>](#) element is being used for purposes other than showing an image, e.g. as part of a service to count page views, then the [alt<sup>p273</sup>](#) attribute must be the empty string.

In such cases, the [width<sup>p397</sup>](#) and [height<sup>p397</sup>](#) attributes should both be set to zero.

#### 4.8.5.1.13 An image in an e-mail or private document intended for a specific person who is known to be able to view images

This section does not apply to documents that are publicly accessible, or whose target audience is not necessarily personally known to the author, such as documents on a Web site, e-mails sent to public mailing lists, or software documentation.

When an image is included in a private communication (such as an HTML e-mail) aimed at a specific person who is known to be able to view images, the [alt<sup>p273</sup>](#) attribute may be omitted. However, even in such cases authors are strongly urged to include alternative text (as appropriate according to the kind of image involved, as described in the above entries), so that the e-mail is still usable should the user use a mail client that does not support images, or should the document be forwarded on to other users whose abilities might not include easily seeing images.

#### 4.8.5.1.14 Guidance for markup generators

Markup generators (such as WYSIWYG authoring tools) should, wherever possible, obtain alternative text from their users. However, it is recognised that in many cases, this will not be possible.

For images that are the sole contents of links, markup generators should examine the link target to determine the title of the target, or the URL of the target, and use information obtained in this manner as the alternative text.

For images that have captions, markup generators should use the [figure<sup>p202</sup>](#) and [figcaption<sup>p205</sup>](#) elements, or the [title<sup>p122</sup>](#) attribute, to provide the image's caption.

As a last resort, implementors should either set the [alt<sup>p273</sup>](#) attribute to the empty string, under the assumption that the image is a purely decorative image that doesn't add any information but is still specific to the surrounding content, or omit the [alt<sup>p273</sup>](#) attribute altogether, under the assumption that the image is a key part of the content.

Markup generators may specify a `generator-unable-to-provide-required-alt` attribute on `imgp272` elements for which they have been unable to obtain alternative text and for which they have therefore omitted the `altp273` attribute. The value of this attribute must be the empty string. Documents containing such attributes are not conforming, but conformance checkers will `silently ignorep299` this error.

**Note** *This is intended to avoid markup generators from being pressured into replacing the error of omitting the `altp273` attribute with the even more egregious error of providing phony alternative text, because state-of-the-art automated conformance checkers cannot distinguish phony alternative text from correct alternative text.*

Markup generators should generally avoid using the image's own file name as the alternative text. Similarly, markup generators should avoid generating alternative text from any content that will be equally available to presentation user agents (e.g. Web browsers).

**Note** *This is because once a page is generated, it will typically not be updated, whereas the browsers that later read the page can be updated by the user, therefore the browser is likely to have more up-to-date and finely-tuned heuristics than the markup generator did when generating the page.*

#### 4.8.5.1.15 Guidance for conformance checkers

A conformance checker must report the lack of an `altp273` attribute as an error unless one of the conditions listed below applies:

- The `imgp272` element is in a `figurep202` element that satisfies [the conditions described above<sup>p297</sup>](#).
- The `imgp272` element has a `titlep122` attribute with a value that is not the empty string (also as [described above<sup>p296</sup>](#)).
- The conformance checker has been configured to assume that the document is an e-mail or document intended for a specific person who is known to be able to view images.
- The `imgp272` element has a (non-conforming) `generator-unable-to-provide-required-altp299` attribute whose value is the empty string. A conformance checker that is not reporting the lack of an `altp273` attribute as an error must also not report the presence of the empty `generator-unable-to-provide-required-altp299` attribute as an error. (This case does not represent a case where the document is conforming, only that the generator could not determine appropriate alternative text — validators are not required to show an error in this case, because such an error might encourage markup generators to include bogus alternative text purely in an attempt to silence validators. Naturally, conformance checkers *may* report the lack of an `altp273` attribute as an error even in the presence of the `generator-unable-to-provide-required-altp299` attribute; for example, there could be a user option to report *all* conformance errors even those that might be the more or less inevitable result of using a markup generator.)

## 4.8.6 The `iframe` element

Spec bugs: [25454](#)

Categories<sup>p113</sup>:

[Flow content<sup>p115</sup>](#).  
[Phrasing content<sup>p116</sup>](#).  
[Embedded content<sup>p116</sup>](#).  
[Interactive content<sup>p116</sup>](#).  
[Palpable content<sup>p117</sup>](#).

Contexts in which this element can be used<sup>p113</sup>:

Where [embedded content<sup>p116</sup>](#) is expected.

Content model<sup>p113</sup>:

Text that conforms to [the requirements given in the prose<sup>p306</sup>](#).

Tag omission in text/html<sup>p113</sup>:

Neither tag is omissible.

Content attributes<sup>p113</sup>:

[Global attributes<sup>p120</sup>](#)

`srcp300` — Address of the resource

`srcdocp300` — A document to render in the `iframep299`

`namep303` — Name of [nested browsing context<sup>b763</sup>](#)

:

sandbox<sup>p303</sup> — Security rules for nested content  
seamless<sup>p304</sup> — Whether to apply the document's styles to the nested content  
allowfullscreen<sup>p306</sup> — Whether to allow the iframe<sup>p299</sup>'s contents to use requestFullscreen()<sup>p52</sup>  
width<sup>p397</sup> — Horizontal dimension  
height<sup>p397</sup> — Vertical dimension

DOM interface<sup>p113</sup>:

IDL

```
interface HTMLFrameElement : HTMLElement {
 attribute DOMString src;
 attribute DOMString srcdoc;
 attribute DOMString name;
 [PutForwards=value] readonly attribute DOMSettableTokenList sandbox;
 attribute boolean seamless;
 attribute boolean allowFullscreen;
 attribute DOMString width;
 attribute DOMString height;
 readonly attribute Document? contentDocument;
 readonly attribute WindowProxy? contentWindow;
 Document? getSVGDocument();
}

// also has obsolete members
};
```

The iframe<sup>p299</sup> element represents<sup>p111</sup> a nested browsing context<sup>p763</sup>.

The src attribute gives the address of a page that the nested browsing context<sup>p763</sup> is to contain. The attribute, if present, must be a valid non-empty URL potentially surrounded by spaces<sup>p82</sup>. If the itemprop<sup>p692</sup> is specified on an iframe<sup>p299</sup> element, then the src<sup>p300</sup> attribute must also be specified.

The srcdoc attribute gives the content of the page that the nested browsing context<sup>p763</sup> is to contain. The value of the attribute is the source of an iframe srcdoc document.  
Spec bugs: 25233

For iframe<sup>p299</sup> elements in HTML documents<sup>p51</sup>, the srcdoc<sup>p300</sup> attribute, if present, must have a value using the HTML syntax<sup>p941</sup> that consists of the following syntactic components, in the given order:

1. Any number of comments<sup>p952</sup> and space characters<sup>p58</sup>.
2. Optionally, a DOCTYPE<sup>p941</sup>.
3. Any number of comments<sup>p952</sup> and space characters<sup>p58</sup>.
4. The root element, in the form of an html<sup>p137</sup> element<sup>p942</sup>.
5. Any number of comments<sup>p952</sup> and space characters<sup>p58</sup>.

For iframe<sup>p299</sup> elements in XML documents<sup>p51</sup>, the srcdoc<sup>p300</sup> attribute, if present, must have a value that matches the production labeled document in the XML specification. [XML]<sup>p1154</sup>

### Example

Here a blog uses the srcdoc<sup>p300</sup> attribute in conjunction with the sandbox<sup>p303</sup> and seamless<sup>p304</sup> attributes described below to provide users of user agents that support this feature with an extra layer of protection from script injection in the blog post comments:

```
<article>
 <h1>I got my own magazine!</h1>
 <p>After much effort, I've finally found a publisher, and so now I
 have my own magazine! Isn't that awesome?! The first issue will come
 out in September, and we have articles about getting food, and about
 getting in boxes, it's going to be great!</p>
 <footer>
```

```

<p>Written by cap, 1 hour ago.
</footer>
<article>
 <footer> Thirteen minutes ago, ch wrote: </footer>
 <iframe seamless sandbox srcdoc=<p>did you get a cover picture yet?"></iframe>
</article>
<article>
 <footer> Nine minutes ago, cap wrote: </footer>
 <iframe seamless sandbox srcdoc=<p>Yeah, you can see it in my gallery."></iframe>
</article>
<article>
 <footer> Five minutes ago, ch wrote: </footer>
 <iframe seamless sandbox srcdoc=<p>hey that's earl's table.
<p>you should get earl&me on the next cover."></iframe>
</article>

```

Notice the way that quotes have to be escaped (otherwise the `srcdoc`<sup>p300</sup> attribute would end prematurely), and the way raw ampersands (e.g. in URLs or in prose) mentioned in the sandboxed content have to be *doubly* escaped — once so that the ampersand is preserved when originally parsing the `srcdoc`<sup>p300</sup> attribute, and once more to prevent the ampersand from being misinterpreted when parsing the sandboxed content.

Furthermore, notice that since the `DOCTYPE`<sup>p941</sup> is optional in `iframe srcdoc documents`<sup>p300</sup>, and the `html`<sup>p137</sup>, `head`<sup>p138</sup>, and `body`<sup>p157</sup> elements have *optional start and end tags*<sup>p946</sup>, and the `title`<sup>p139</sup> element is also optional in `iframe srcdoc documents`<sup>p300</sup>, the markup in a `srcdoc`<sup>p300</sup> attribute can be relatively succinct despite representing an entire document, since only the contents of the `body`<sup>p157</sup> element need appear literally in the syntax. The other elements are still present, but only by implication.

**Note** In the [HTML syntax](#)<sup>p941</sup>, authors need only remember to use U+0022 QUOTATION MARK characters ("") to wrap the attribute contents and then to escape all U+0022 QUOTATION MARK ("") and U+0026 AMPERSAND (&) characters, and to specify the `sandbox`<sup>p303</sup> attribute, to ensure safe embedding of content.

**Note** Due to restrictions of the [XHTML syntax](#)<sup>p1054</sup>, in XML the U+003C LESS-THAN SIGN character (<) needs to be escaped as well. In order to prevent [attribute-value normalization](#), some of XML's whitespace characters — specifically U+0009 CHARACTER TABULATION (tab), U+000A LINE FEED (LF), and U+000D CARRIAGE RETURN (CR) — also need to be escaped. [\[XML\]](#)<sup>p1154</sup>

**Note** If the `src`<sup>p299</sup> attribute and the `srcdoc`<sup>p300</sup> attribute are both specified together, the `srcdoc`<sup>p300</sup> attribute takes priority. This allows authors to provide a fallback [URL](#)<sup>p48</sup> for legacy user agents that do not support the `srcdoc`<sup>p300</sup> attribute.

When an `iframe`<sup>p299</sup> element is [inserted into a document](#)<sup>p42</sup> that has a [browsing context](#)<sup>p762</sup>, the user agent must [create](#)<sup>p762</sup> a [nested browsing context](#)<sup>p763</sup>, and then [process the iframe attributes](#)<sup>p301</sup> for the "first time".

When an `iframe`<sup>p299</sup> element is [removed from a document](#)<sup>p42</sup>, the user agent must [discard](#)<sup>p774</sup> the [nested browsing context](#)<sup>p763</sup>, if any.

**Note** This happens without any [unload](#)<sup>p1145</sup> events firing (the [nested browsing context](#)<sup>p763</sup> and its [Document](#)<sup>p102</sup> are discarded<sup>p774</sup>, not unloaded<sup>p805</sup>).

Whenever an `iframe`<sup>p299</sup> element with a [nested browsing context](#)<sup>p763</sup> has its `srcdoc`<sup>p300</sup> attribute set, changed, or removed, the user agent must [process the iframe attributes](#)<sup>p301</sup>.

Similarly, whenever an `iframe`<sup>p299</sup> element with a [nested browsing context](#)<sup>p763</sup> but with no `srcdoc`<sup>p300</sup> attribute specified has its `src`<sup>p300</sup> attribute set, changed, or removed, the user agent must [process the iframe attributes](#)<sup>p301</sup>.

When the user agent is to [process the iframe attributes](#), it must run the first appropriate steps from the following list:

↪ If the `srcdoc`<sup>p300</sup> attribute is specified

Navigate<sup>p791</sup> the element's [child browsing context](#)<sup>p763</sup> to a resource whose [Content-Type](#)<sup>p86</sup> is [text/html](#)<sup>p1116</sup>, whose [URL](#)<sup>p48</sup> is [about:srcdoc](#)<sup>p82</sup>, and whose data consists of the value of the attribute. The resulting [Document](#)<sup>p102</sup> must be considered an [iframe srcdoc document](#)<sup>p300</sup>.

↪ Otherwise, if the element has no `src`<sup>p300</sup> attribute specified, and the user agent is processing the `iframe`<sup>p299</sup>'s attributes for the "first time"

Queue a task<sup>p835</sup> to run the `iframe load event steps`<sup>p302</sup>.

The `task source`<sup>p835</sup> for this `task`<sup>p834</sup> is the `DOM manipulation task source`<sup>p838</sup>.

↪ Otherwise

1. If the value of the `src`<sup>p300</sup> attribute is missing, or its value is the empty string, let `url` be the string "`about:blank`"<sup>p84</sup>.

Otherwise, `resolve`<sup>p82</sup> the value of the `src`<sup>p300</sup> attribute, relative to the `iframe`<sup>p299</sup> element.

If that is not successful, then let `url` be the string "`about:blank`"<sup>p84</sup>. Otherwise, let `url` be the resulting `absolute URL`<sup>p48</sup>.

2. If there exists an `ancestor browsing context`<sup>p763</sup> whose `active document`<sup>p762</sup>'s `address`, ignoring fragment identifiers, is equal to `url`, then abort these steps.

3. `Navigate`<sup>p791</sup> the element's `child browsing context`<sup>p763</sup> to `url`.

Any `navigation`<sup>p791</sup> required of the user agent in the `process the iframe attributes`<sup>p301</sup> algorithm must be completed as an `explicit self-navigation override`<sup>p791</sup> and with the `iframe`<sup>p299</sup> element's `node document`'s `browsing context`<sup>p762</sup> as the `source browsing context`<sup>p791</sup>.

Furthermore, if the `active document`<sup>p762</sup> of the element's `child browsing context`<sup>p763</sup> before such a `navigation`<sup>p791</sup> was not `completely loaded`<sup>p1033</sup> at the time of the new `navigation`<sup>p791</sup>, then the `navigation`<sup>p791</sup> must be completed with `replacement enabled`<sup>p802</sup>.

Similarly, if the `child browsing context`<sup>p763</sup>'s `session history`<sup>p782</sup> contained only one `Document`<sup>p102</sup> when the `process the iframe attributes`<sup>p301</sup> algorithm was invoked, and that was the `about:blank`<sup>p84</sup> `Document`<sup>p102</sup> created when the `child browsing context`<sup>p763</sup> was created, then any `navigation`<sup>p791</sup> required of the user agent in that algorithm must be completed with `replacement enabled`<sup>p802</sup>.

When a `Document`<sup>p102</sup> in an `iframe`<sup>p299</sup> is marked as `completely loaded`<sup>p1033</sup>, the user agent must run the `iframe load event steps`<sup>p302</sup> `in parallel`<sup>p41</sup>.

**Note** A `load`<sup>p1144</sup> event is also fired at the `iframe`<sup>p299</sup> element when it is created if no other data is loaded in it.

Each `Document`<sup>p102</sup> has an `iframe load in progress` flag and a `mute iframe load` flag. When a `Document`<sup>p102</sup> is created, these flags must be unset for that `Document`<sup>p102</sup>.

The `iframe load event steps` are as follows:

1. Let `child document` be the `active document`<sup>p762</sup> of the `iframe`<sup>p299</sup> element's `nested browsing context`<sup>p763</sup>.
2. If `child document` has its `mute iframe load`<sup>p302</sup> flag set, abort these steps.
3. Set `child document`'s `iframe load in progress`<sup>p302</sup> flag.
4. `Fire a simple event`<sup>p846</sup> named `load`<sup>p1144</sup> at the `iframe`<sup>p299</sup> element.
5. Unset `child document`'s `iframe load in progress`<sup>p302</sup> flag.

This, in conjunction with scripting, can be used to probe the URL space of the local network's HTTP servers. User agents may implement cross-origin<sup>p776</sup> access control policies that are stricter than those described above to mitigate this attack, but unfortunately such policies are typically not compatible with existing Web content.

When the `iframe`<sup>p299</sup>'s `browsing context`<sup>p762</sup>'s `active document`<sup>p762</sup> is not `ready for post-load tasks`<sup>p1033</sup>, and when anything in the `iframe`<sup>p299</sup> is `delaying the load event`<sup>p1033</sup> of the `iframe`<sup>p299</sup>'s `browsing context`<sup>p762</sup>'s `active document`<sup>p762</sup>, and when the `iframe`<sup>p299</sup>'s `browsing context`<sup>p762</sup> is in the `delaying load events mode`<sup>p763</sup>, the `iframe`<sup>p299</sup> must `delay the load event`<sup>p1033</sup> of its document.

**Note** If, during the handling of the `load`<sup>p1144</sup> event, the `browsing context`<sup>p762</sup> in the `iframe`<sup>p299</sup> is again `navigated`<sup>p791</sup>, that will further `delay the load event`<sup>p1033</sup>.

**Note** If, when the element is created, the `srcdoc`<sup>p300</sup> attribute is not set, and the `src`<sup>p300</sup> attribute is either also not set or set but its value cannot be `resolved`<sup>p82</sup>, the `browsing context` will remain at the initial `about:blank`<sup>p84</sup> page.

**Note** If the user [navigates](#) away from this page, the [iframe](#)'s corresponding [WindowProxy](#) object will proxy new [Window](#) objects for new [Document](#) objects, but the [src](#) attribute will not change.

The [name](#) attribute, if present, must be a [valid browsing context name](#). The given value is used to name the [nested browsing context](#). When the browsing context is created, if the attribute is present, the [browsing context name](#) must be set to the value of this attribute; otherwise, the [browsing context name](#) must be set to the empty string.

Whenever the [name](#) attribute is set, the nested [browsing context](#)'s [name](#) must be changed to the new value. If the attribute is removed, the [browsing context name](#) must be set to the empty string.

The [sandbox](#) attribute, when specified, enables a set of extra restrictions on any content hosted by the [iframe](#). Its value must be an [unordered set of unique space-separated tokens](#) that are [ASCII case-insensitive](#). The allowed values are [allow-forms](#), [allow-pointer-lock](#), [allow-popups](#), [allow-same-origin](#), [allow-scripts](#), and [allow-top-navigation](#).

When the attribute is set, the content is treated as being from a unique [origin](#), forms, scripts, and various potentially annoying links are prevented from targeting other [browsing contexts](#), and plugins are secured. The [allow-same-origin](#) keyword content to be treated as being from its real origin instead of forcing it into a unique origin; the [allow-top-navigation](#) keyword content to [navigate](#) its [top-level browsing context](#); and the [allow-forms](#), [allow-pointer-lock](#), [allow-popups](#) keywords re-enable forms, the pointer lock API, popups, and scripts respectively. [POINTERLOCK]

Source: caniuse.com

**⚠ Warning!** Setting both the [allow-scripts](#) and [allow-same-origin](#) keywords together when the embed same origin as the page containing the [iframe](#) allows the embedded page to simply remove the [sandbox](#) attribute and then reload itself, effectively breaking out of the sandbox altogether.

**⚠ Warning!** These flags only take effect when the [nested browsing context](#) of the [iframe](#) is [navigated](#). Removing them, or removing the entire [sandbox](#) attribute, has no effect on an already-loaded page.

**⚠ Warning!** Potentially hostile files should not be served from the same server as the file containing the [iframe](#) element. Sandboxing hostile content is of minimal help if an attacker can convince the user to just visit the hostile content directly, rather than in the [iframe](#). To limit the damage that can be caused by hostile HTML content, it should be served from a separate dedicated domain. Using a different domain ensures that scripts in the files are unable to attack the site, even if the user is tricked into visiting those pages directly, without the protection of the [sandbox](#) attribute.

When an [iframe](#) element with a [sandbox](#) attribute has its [nested browsing context](#) created (before the initial [about:blank](#) [Document](#) is created), and when an [iframe](#) element's [sandbox](#) attribute is set or changed while it has a [nested browsing context](#), the user agent must [parse the sandboxing directive](#) using the attribute's value as the input, the [iframe](#) element's [nested browsing context](#)'s [iframe sandboxing flag set](#) as the output, and, if the [iframe](#) has an [allowfullscreen](#) attribute, the [allow fullscreen flag](#).

When an [iframe](#) element's [sandbox](#) attribute is removed while it has a [nested browsing context](#), the user agent must empty the [iframe](#) element's [nested browsing context](#)'s [iframe sandboxing flag set](#) as the output.

### Example

In this example, some completely-unknown, potentially hostile, user-provided HTML content is embedded in a page. Because it is served from a separate domain, it is affected by all the normal cross-site restrictions. In addition, the embedded page has scripting disabled, plugins disabled, forms disabled, and it cannot navigate any frames or windows other than itself (or any frames or windows it itself embeds).

```
<p>We're not scared of you! Here is your content, unedited:</p>
<iframe sandbox src="http://usercontent.example.net/getusercontent.cgi?id=12193"></iframe>
```

**⚠ Warning!** It is important to use a separate domain so that if the attacker convinces the user to visit that page directly, the page doesn't run in the context of the site's origin, which would make the user vulnerable to any attack found in the page.

### Example

In this example, a gadget from another site is embedded. The gadget has scripting and forms enabled, and the origin sandbox restrictions are lifted, allowing the gadget to communicate with its originating server. The sandbox is still useful, however, as it disables plugins and popups, thus reducing the risk of the user being exposed to malware and other annoyances.

```
<iframe sandbox="allow-same-origin allow-forms allow-scripts"
src="http://maps.example.com/embedded.html"></iframe>
```

### Example

Suppose a file A contained the following fragment:

```
<iframe sandbox="allow-same-origin allow-forms" src=B></iframe>
```

Suppose that file B contained an iframe also:

```
<iframe sandbox="allow-scripts" src=C></iframe>
```

Further, suppose that file C contained a link:

```
Link
```

For this example, suppose all the files were served as [text/html](#).

Page C in this scenario has all the sandboxing flags set. Scripts are disabled, because the [iframe](#) in A has scripts disabled, and this overrides the [allow-scripts](#) keyword set on the [iframe](#) in B. Forms are also disabled, because the inner [iframe](#) (in B) does not have the [allow-forms](#) keyword set.

Suppose now that a script in A removes all the [sandbox](#) attributes in A and B. This would change nothing immediately. If the user clicked the link in C, loading page D into the [iframe](#) in B, page D would now act as if the [iframe](#) in B had the [allow-same-origin](#) and [allow-forms](#) keywords set, because that was the state of the [nested browsing context](#) in the [iframe](#) in A when page B was loaded.

Generally speaking, dynamically removing or changing the [sandbox](#) attribute is ill-advised, because it can make it quite hard to reason about what will be allowed and what will not.

The [seamless](#) attribute is a [boolean attribute](#). When specified, it indicates that the [iframe](#) element's [browsing context](#) is to be rendered in a manner that makes it appear to be part of the containing document (seamlessly included in the parent document).

### Example

An HTML inclusion is effected using this attribute as in the following example. In this case, the inclusion is of a site-wide nature. Any links in the [iframe](#) will, in new user agents, be automatically opened in the [iframe](#)'s parent browsing context. In older user agents, the site could also include a [base](#) element with a [target](#) attribute with the value [\\_parent](#). Similarly, the styles of the parent page will be automatically applied to the contents of the frame, but to support legacy users, one might wish to include the styles explicitly.

```
<!DOCTYPE HTML>
<title>Mirror Mirror – MovieInfo™</title>
<header>
 <hgroup>
 <h1>Mirror Mirror</h1>
 <h2>Part of the MovieInfo™ Database</h2>
 </hgroup>
 <nav>
 <iframe seamless src="nav.inc"></iframe>
 </nav>
</header>
...
```

An [iframe](#) element is said to be in **seamless mode** when all of the following conditions are met:

- The [seamless](#) attribute is set on the [iframe](#) element, and

- The [`iframe`](#)<sup>p299</sup> element's owner [`Document`](#)<sup>p102</sup>'s [`active sandboxing flag set`](#)<sup>p782</sup> does not have the [`sandboxed seamless iframes flag`](#)<sup>p780</sup> set, and
- Either:
  - The [`browsing context`](#)<sup>p762</sup>'s [`active document`](#)<sup>p762</sup> has the [`same origin`](#)<sup>p778</sup> as the [`iframe`](#)<sup>p299</sup> element's [`node document`](#), or
  - The [`browsing context`](#)<sup>p762</sup>'s [`active document`](#)<sup>p762</sup>'s [`address`](#) has the [`same origin`](#)<sup>p778</sup> as the [`iframe`](#)<sup>p299</sup> element's [`node document`](#), or
  - The [`browsing context`](#)<sup>p762</sup>'s [`active document`](#)<sup>p762</sup> is [`an iframe srcdoc document`](#)<sup>p300</sup>.

When an [`iframe`](#)<sup>p299</sup> element is [`in seamless mode`](#)<sup>p304</sup>, the following requirements apply:

- The user agent must set the [`seamless browsing context flag`](#) to true for that [`browsing context`](#)<sup>p762</sup>. This will [`cause links to open in the parent browsing context`](#)<sup>p791</sup> unless an [`explicit self-navigation override`](#)<sup>p791</sup> is used (`target="self"`).
- Media queries in the context of the [`iframe`](#)<sup>p299</sup>'s [`browsing context`](#)<sup>p762</sup> (e.g. on [`media`](#)<sup>p154</sup> attributes of [`style`](#)<sup>p154</sup> elements in [`Document`](#)<sup>p102</sup>s in that [`iframe`](#)<sup>p299</sup>) must be evaluated with respect to the nearest [`ancestor browsing context`](#)<sup>p763</sup> that is not itself being [`nested through`](#)<sup>p763</sup> an [`iframe`](#)<sup>p299</sup> that is [`in seamless mode`](#)<sup>p304</sup>. [MQI]<sup>p1151</sup>
- In a CSS-supporting user agent: the user agent must add all the style sheets that apply to the [`iframe`](#)<sup>p299</sup> element to the cascade of the [`active document`](#)<sup>p762</sup> of the [`iframe`](#)<sup>p299</sup> element's [`nested browsing context`](#)<sup>p763</sup>, at the appropriate cascade levels, before any style sheets specified by the document itself.
- In a CSS-supporting user agent: the user agent must, for the purpose of CSS property inheritance only, treat the root element of the [`active document`](#)<sup>p762</sup> of the [`iframe`](#)<sup>p299</sup> element's [`nested browsing context`](#)<sup>p763</sup> as being a child of the [`iframe`](#)<sup>p299</sup> element. (Thus inherited properties on the root element of the document in the [`iframe`](#)<sup>p299</sup> will inherit the computed values of those properties on the [`iframe`](#)<sup>p299</sup> element instead of taking their initial values.)
- In visual media, in a CSS-supporting user agent: the user agent should set the intrinsic width of the [`iframe`](#)<sup>p299</sup> to the width that the element would have if it was a non-replaced block-level element with 'width: auto', unless that width would be zero (e.g. if the element is floating or absolutely positioned), in which case the user agent should set the intrinsic width of the [`iframe`](#)<sup>p299</sup> to the shrink-to-fit width of the root element (if any) of the content rendered in the [`iframe`](#)<sup>p299</sup>.
- In visual media, in a CSS-supporting user agent: the user agent should set the intrinsic height of the [`iframe`](#)<sup>p299</sup> to the shortest height that would make the content rendered in the [`iframe`](#)<sup>p299</sup> at its current width (as given in the previous bullet point) have no scrollable overflow at its bottom edge. Scrollable overflow is any overflow that would increase the range to which a scrollbar or other scrolling mechanism can scroll.
- In visual media, in a CSS-supporting user agent: the user agent must force the height of the initial containing block of the [`active document`](#)<sup>p762</sup> of the [`nested browsing context`](#)<sup>p763</sup> of the [`iframe`](#)<sup>p299</sup> to zero.

**Note** *This is intended to get around the otherwise circular dependency of percentage dimensions that depend on the height of the containing block, thus affecting the height of the document's bounding box, thus affecting the height of the viewport, thus affecting the size of the initial containing block.*

- In speech media, the user agent should render the [`nested browsing context`](#)<sup>p763</sup> without announcing that it is a separate document.
- User agents should, in general, act as if the [`active document`](#)<sup>p762</sup> of the [`iframe`](#)<sup>p299</sup>'s [`nested browsing context`](#)<sup>p763</sup> was part of the document that the [`iframe`](#)<sup>p299</sup> is in, if any.

**Example** For example if the user agent supports listing all the links in a document, links in "seamlessly" nested documents would be included in that list without being significantly distinguished from links in the document itself.

- The [`nested browsing context`](#)<sup>p763</sup>'s [`Window`](#)<sup>p768</sup> object's [`cross-boundary event parent`](#)<sup>p51</sup> is the [`browsing context container`](#)<sup>p763</sup>. [DOM]<sup>p1149</sup>

If the attribute is not specified, or if the [`origin`](#)<sup>p776</sup> conditions listed above are not met, then the user agent should render the [`nested browsing context`](#)<sup>p763</sup> in a manner that is clearly distinguishable as a separate [`browsing context`](#)<sup>p762</sup>, and the [`seamless browsing context flag`](#)<sup>p305</sup> must be set to false for that [`browsing context`](#)<sup>p762</sup>.

**⚠ Warning!** *It is important that user agents recheck the above conditions whenever the [`active document`](#)<sup>p762</sup> of the [`nested browsing context`](#)<sup>p763</sup> of the [`iframe`](#)<sup>p299</sup> changes, such that the [`seamless browsing context flag`](#)<sup>p305</sup> gets unset if the [`nested browsing context`](#)<sup>p763</sup> is navigated<sup>p791</sup> to another origin.*

**Note** *The attribute can be set or removed dynamically, with the rendering updating in tandem.*

**Note** The `contenteditable`<sup>p739</sup> attribute does not propagate into `seamless`<sup>p304</sup> `iframe`<sup>p299</sup>s.

The `allowfullscreen` attribute is a `boolean attribute`<sup>p59</sup>. When specified, it indicates that `Document`<sup>p102</sup> objects in the `iframe`<sup>p299</sup> element's `browsing context`<sup>p762</sup> are to be allowed to use `requestFullscreen()`<sup>p52</sup> (if it's not blocked for other reasons, e.g. there is another ancestor `iframe`<sup>p299</sup> without this attribute set).

**Example**

Here, an `iframe`<sup>p299</sup> is used to embed a player from a video site. The `allowfullscreen`<sup>p306</sup> attribute is needed to enable the player to show its video full-screen.

```
<article>
 <header>
 <p> Fred Flintstone</p>
 <p>12:44 - Private
Post</p>
 </header>
 <main>
 <p>Check out my new ride!</p>
 <iframe src="https://video.example.com/embed?id=92469812" allowfullscreen></iframe>
 </main>
</article>
```

The `iframe`<sup>p299</sup> element supports `dimension attributes`<sup>p397</sup> for cases where the embedded content has specific dimensions (e.g. ad units have well-defined dimensions).

An `iframe`<sup>p299</sup> element never has `fallback content`<sup>p116</sup>, as it will always `create`<sup>p762</sup> a nested `browsing context`<sup>p762</sup>, regardless of whether the specified initial contents are successfully used.

Descendants of `iframe`<sup>p299</sup> elements represent nothing. (In legacy user agents that do not support `iframe`<sup>p299</sup> elements, the contents would be parsed as markup that could act as fallback content.)

When used in `HTML documents`<sup>p51</sup>, the allowed content model of `iframe`<sup>p299</sup> elements is text, except that invoking the `HTML fragment parsing algorithm`<sup>p1043</sup> with the `iframe`<sup>p299</sup> element as the `context`<sup>p1043</sup> element and the text contents as the `input` must result in a list of nodes that are all `phrasing content`<sup>p116</sup>, with no `parse errors`<sup>p953</sup> having occurred, with no `script`<sup>p591</sup> elements being anywhere in the list or as descendants of elements in the list, and with all the elements in the list (including their descendants) being themselves conforming.

The `iframe`<sup>p299</sup> element must be empty in `XML documents`<sup>p51</sup>.

**Note** The `HTML parser`<sup>p952</sup> treats markup inside `iframe`<sup>p299</sup> elements as text.

The IDL attributes `src`, `srcdoc`, `name`, `sandbox`, and `seamless` must `reflect`<sup>p88</sup> the respective content attributes of the same name.

The `allowFullscreen` IDL attribute must `reflect`<sup>p88</sup> the `allowfullscreen`<sup>p306</sup> content attribute.

The `contentDocument` IDL attribute must return the `Document`<sup>p102</sup> object of the `active document`<sup>p762</sup> of the `iframe`<sup>p299</sup> element's `nested browsing context`<sup>p763</sup>, if any and if its `effective script origin`<sup>p776</sup> is the `same origin`<sup>p778</sup> as the `effective script origin`<sup>p776</sup> specified by the `incumbent settings object`<sup>p831</sup>, or null otherwise.

The `contentWindow` IDL attribute must return the `WindowProxy`<sup>p775</sup> object of the `iframe`<sup>p299</sup> element's `nested browsing context`<sup>p763</sup>, if any, or null otherwise.

**Example**

Here is an example of a page using an `iframe`<sup>p299</sup> to include advertising from an advertising broker:

```
<iframe src="http://ads.example.com/?customerid=923513721&format=banner"
width="468" height="60"></iframe>
```

## 4.8.7 The `embed` element

Categories<sup>p113</sup>:

[Flow content<sup>p115</sup>](#).  
[Phrasing content<sup>p116</sup>](#).  
[Embedded content<sup>p116</sup>](#).  
[Interactive content<sup>p116</sup>](#).  
[Palpable content<sup>p117</sup>](#).

Contexts in which this element can be used<sup>p113</sup>:

Where [embedded content<sup>p116</sup>](#) is expected.

Content model<sup>p113</sup>:

[Nothing<sup>p114</sup>](#).

Tag omission in text/html<sup>p113</sup>:

No [end tag<sup>p944</sup>](#).

Content attributes<sup>p113</sup>:

[Global attributes<sup>p120</sup>](#)

[src<sup>p307</sup>](#) — Address of the resource  
[type<sup>p307</sup>](#) — Type of embedded resource  
[width<sup>p397</sup>](#) — Horizontal dimension  
[height<sup>p397</sup>](#) — Vertical dimension

Any other attribute that has no namespace (see prose).

DOM interface<sup>p113</sup>:

```
IDL
interface HTMLEmbedElement : HTMLElement {
 attribute DOMString src;
 attribute DOMString type;
 attribute DOMString width;
 attribute DOMString height;
 Document? getSVGDocument();
 legacycaller any (any... arguments);

 // also has obsolete members
};
```

Depending on the type of content instantiated by the [embed<sup>p307</sup>](#) element, the node may also support other interfaces.

The [embed<sup>p307</sup>](#) element provides an integration point for an external (typically non-HTML) application or interactive content.

The [src](#) attribute gives the address of the resource being embedded. The attribute, if present, must contain a [valid non-empty URL potentially surrounded by spaces<sup>p82</sup>](#).

If the [itemprop<sup>p692</sup>](#) attribute is specified on an [embed<sup>p307</sup>](#) element, then the [src<sup>p307</sup>](#) attribute must also be specified.

The [type](#) attribute, if present, gives the [MIME type<sup>p42</sup>](#) by which the plugin to instantiate is selected. The value must be a [valid MIME type<sup>p42</sup>](#). If both the [type<sup>p307</sup>](#) attribute and the [src<sup>p307</sup>](#) attribute are present, then the [type<sup>p307</sup>](#) attribute must specify the same type as the [explicit Content-Type metadata<sup>p86</sup>](#) of the resource given by the [src<sup>p307</sup>](#) attribute.

While any of the following conditions are occurring, any [plugin<sup>p43</sup>](#) instantiated for the element must be removed, and the [embed<sup>p307</sup>](#) element [represents<sup>p111</sup>](#) nothing:

- The element has neither a [src<sup>p307</sup>](#) attribute nor a [type<sup>p307</sup>](#) attribute.
- The element has a [media element<sup>p326</sup>](#) ancestor.
- The element has an ancestor [object<sup>p310</sup>](#) element that is *not* showing its [fallback content<sup>p116</sup>](#).

An [embed<sup>p307</sup>](#) element is said to be **potentially active** when the following conditions are all met simultaneously:

- The element is [in a Document<sup>p42</sup>](#) or was [in a Document<sup>p42</sup>](#) the last time the [event loop<sup>p834</sup>](#) reached [step 1<sup>p836</sup>](#).

- The element's [node document](#) is [fully active](#)<sup>p763</sup>.
- The element has either a [src](#)<sup>b307</sup> attribute set or a [type](#)<sup>b307</sup> attribute set (or both).
- The element's [src](#)<sup>p307</sup> attribute is either absent or its value is not the empty string.
- The element is not a descendant of a [media element](#)<sup>p326</sup>.
- The element is not a descendant of an [object](#)<sup>p310</sup> element that is not showing its [fallback content](#)<sup>p116</sup>.
- The element is [being rendered](#)<sup>p1058</sup>, or was [being rendered](#)<sup>p1058</sup> the last time the [event loop](#)<sup>p834</sup> reached [step 1](#)<sup>p836</sup>.

Whenever an [embed](#)<sup>p307</sup> element that was not [potentially active](#)<sup>p307</sup> becomes [potentially active](#)<sup>p307</sup>, and whenever a [potentially active](#)<sup>p307</sup> [embed](#)<sup>p307</sup> element that is remaining [potentially active](#)<sup>p307</sup> and has its [src](#)<sup>p307</sup> attribute set, changed, or removed or its [type](#)<sup>b307</sup> attribute set, changed, or removed, the user agent must [queue a task](#)<sup>p835</sup> using the [embed task source](#) to run [the embed element setup steps](#)<sup>p308</sup>.

The [embed](#) element setup steps are as follows:

1. If another [task](#)<sup>p834</sup> has since been queued to run [the embed element setup steps](#)<sup>p308</sup> for this element, then abort these steps.

#### 2. If the element has a [src](#)<sup>p307</sup> attribute set

The user agent must [resolve](#)<sup>p82</sup> the value of the element's [src](#)<sup>p307</sup> attribute, relative to the element. If that is successful, the user agent should [fetch](#)<sup>p84</sup> the resulting [absolute URL](#)<sup>p48</sup>, from the element's [browsing context scope origin](#)<sup>p765</sup> if it has one. The [task](#)<sup>p834</sup> that is [queued](#)<sup>p835</sup> by the [networking task source](#)<sup>p839</sup> once the resource has been [fetched](#)<sup>p84</sup> must run the following steps:

1. If another [task](#)<sup>p834</sup> has since been queued to run [the embed element setup steps](#)<sup>p308</sup> for this element, then abort these steps.
2. Determine the **type of the content** being embedded, as follows (stopping at the first substep that determines the type):
  1. If the element has a [type](#)<sup>b307</sup> attribute, and that attribute's value is a type that a [plugin](#)<sup>p43</sup> supports, then the value of the [type](#)<sup>p307</sup> attribute is the [content's type](#)<sup>p308</sup>.
  2. Otherwise, if applying the [URL parser](#)<sup>p48</sup> algorithm to the [URL](#)<sup>p48</sup> of the specified resource (after any redirects) results in a [parsed URL](#)<sup>p48</sup> whose [path](#)<sup>p48</sup> component matches a pattern that a [plugin](#)<sup>p43</sup> supports, then the [content's type](#)<sup>p308</sup> is the type that that plugin can handle.

**Example** For example, a plugin might say that it can handle resources with [path](#)<sup>p48</sup> components that end with the four character string ".swf".

3. Otherwise, if the specified resource has [explicit Content-Type metadata](#)<sup>p86</sup>, then that is the [content's type](#)<sup>p308</sup>.
4. Otherwise, the content has no [type](#)<sup>p308</sup> and there can be no appropriate [plugin](#)<sup>p43</sup> for it.
3. If the previous step determined that the [content's type](#)<sup>p308</sup> is [image/svg+xml](#), then run the following substeps:
  1. If the [embed](#)<sup>p307</sup> element is not associated with a [nested browsing context](#)<sup>p763</sup>, associate the element with a newly created [nested browsing context](#)<sup>b763</sup>, and, if the element has a [name](#)<sup>p1097</sup> attribute, set the [browsing context name](#)<sup>p765</sup> of the element's [nested browsing context](#)<sup>p763</sup> to the value of this attribute.
  2. [Navigate](#)<sup>p791</sup> the [nested browsing context](#)<sup>p763</sup> to the fetched resource, with [replacement enabled](#)<sup>p802</sup>, and with the [embed](#)<sup>p307</sup> element's [node document](#)'s [browsing context](#)<sup>p762</sup> as the [source browsing context](#)<sup>p791</sup>. (The [src](#)<sup>p307</sup> attribute of the [embed](#)<sup>p307</sup> element doesn't get updated if the browsing context gets further navigated to other locations.)
  3. The [embed](#)<sup>p307</sup> element now [represents](#)<sup>p111</sup> its associated [nested browsing context](#)<sup>p763</sup>.
4. Otherwise, find and instantiate an appropriate [plugin](#)<sup>p43</sup> based on the [content's type](#)<sup>p308</sup>, and hand that [plugin](#)<sup>p43</sup> the content of the resource, replacing any previously instantiated plugin for the element. The [embed](#)<sup>p307</sup> element now represents this [plugin](#)<sup>p43</sup> instance.
5. Once the resource or plugin has completely loaded, [queue a task](#)<sup>p835</sup> to fire a simple event<sup>p846</sup> named [load](#)<sup>p1144</sup> at the element.

Whether the resource is fetched successfully or not (e.g. whether the response code was a 2xx code [or equivalent](#)<sup>p83</sup>) must be ignored when determining the [content's type](#)<sup>p308</sup> and when handing the resource to the plugin.

**Note** This allows servers to return data for plugins even with error responses (e.g. HTTP 500 Internal Server Error codes can still contain plugin data).

Fetching the resource must [delay the load event<sup>p1033</sup>](#) of the element's [node document](#).

↪ If the element has no [src<sup>p307</sup>](#) attribute set

The user agent should find and instantiate an appropriate [plugin<sup>p43</sup>](#) based on the value of the [type<sup>p307</sup>](#) attribute. The [embed<sup>p307</sup>](#) element now represents this [plugin<sup>p43</sup>](#) instance.

Once the plugin is completely loaded, [queue a task<sup>p835</sup>](#) to [fire a simple event<sup>p846</sup>](#) named [load<sup>p1144</sup>](#) at the element.

The [embed<sup>p307</sup>](#) element has no [fallback content<sup>p116</sup>](#). If the user agent can't find a suitable plugin when attempting to find and instantiate one for the algorithm above, then the user agent must use a default plugin. This default could be as simple as saying "Unsupported Format".

Whenever an [embed<sup>p307</sup>](#) element that was [potentially active<sup>p307</sup>](#) stops being [potentially active<sup>p307</sup>](#), any [plugin<sup>p43</sup>](#) that had been instantiated for that element must be unloaded.

When a [plugin<sup>p43</sup>](#) is to be instantiated but it cannot be [secured<sup>p43</sup>](#) and the [sandboxed plugins browsing context flag<sup>p780</sup>](#) is set on the [embed<sup>p307</sup>](#) element's [node document's active sandboxing flag set<sup>p782</sup>](#), then the user agent must not instantiate the [plugin<sup>p43</sup>](#), and must instead render the [embed<sup>p307</sup>](#) element in a manner that conveys that the [plugin<sup>p43</sup>](#) was disabled. The user agent may offer the user the option to override the sandbox and instantiate the [plugin<sup>p43</sup>](#) anyway; if the user invokes such an option, the user agent must act as if the conditions above did not apply for the purposes of this element.

**⚠ Warning!** *Plugins that cannot be secured<sup>p43</sup> are disabled in sandboxed browsing contexts because they might not honor the restrictions imposed by the sandbox (e.g. they might allow scripting even when scripting in the sandbox is disabled). User agents should convey the danger of overriding the sandbox to the user if an option to do so is provided.*

When an [embed<sup>p307</sup>](#) element represents a [nested browsing context<sup>p763</sup>](#): if the [embed<sup>p307</sup>](#) element's [nested browsing context<sup>p763</sup>'s active document<sup>p762</sup>](#) is not [ready for post-load tasks<sup>p1033</sup>](#), and when anything is [delaying the load event<sup>p1033</sup>](#) of the [embed<sup>p307</sup>](#) element's [browsing context<sup>p762</sup>'s active document<sup>p762</sup>](#), and when the [embed<sup>p307</sup>](#) element's [browsing context<sup>p762</sup>](#) is in the [delaying load events mode<sup>p763</sup>](#), the [embed<sup>p307</sup>](#) must [delay the load event<sup>p1033</sup>](#) of its document.

The [task source<sup>p835</sup>](#) for the [tasks<sup>p834</sup>](#) mentioned in this section is the [DOM manipulation task source<sup>p838</sup>](#).

Any namespace-less attribute other than [name<sup>p1097</sup>](#), [align<sup>p1100</sup>](#), [hspace<sup>p1100</sup>](#), and [vspace<sup>p1100</sup>](#) may be specified on the [embed<sup>p307</sup>](#) element, so long as its name is [XML-compatible<sup>p42</sup>](#) and contains no [uppercase ASCII letters<sup>p58</sup>](#). These attributes are then passed as parameters to the [plugin<sup>p43</sup>](#).

**Note** All attributes in [HTML documents<sup>p51</sup>](#) get lowercased automatically, so the restriction on uppercase letters doesn't affect such documents.

**Note** The four exceptions are to exclude legacy attributes that have side-effects beyond just sending parameters to the [plugin<sup>p43</sup>](#).

The user agent should pass the names and values of all the attributes of the [embed<sup>p307</sup>](#) element that have no namespace to the [plugin<sup>p43</sup>](#) used, when one is instantiated.

The [HTMLEmbedElement<sup>p307</sup>](#) object representing the element must expose the scriptable interface of the [plugin<sup>p43</sup>](#) instantiated for the [embed<sup>p307</sup>](#) element, if any. At a minimum, this interface must implement the **legacy caller operation**. (It is suggested that the default behaviour of this legacy caller operation, e.g. the behaviour of the default plugin's legacy caller operation, be to throw a [NotSupportedError<sup>p50</sup>](#) exception.)

The [embed<sup>p307</sup>](#) element supports [dimension attributes<sup>p397</sup>](#).

The IDL attributes [src](#) and [type](#) each must [reflect<sup>p88</sup>](#) the respective content attributes of the same name.

**Example**

Here's a way to embed a resource that requires a proprietary plugin, like Flash:

```
<embed src="catgame.swf">
```

If the user does not have the plugin (for example if the plugin vendor doesn't support the user's platform), then the user will be unable to use the resource.

To pass the plugin a parameter "quality" with the value "high", an attribute can be specified:

```
<embed src="catgame.swf" quality="high">
```

This would be equivalent to the following, when using an [object](#) element instead:

```
<object data="catgame.swf">
 <param name="quality" value="high">
</object>
```

Spec bugs: [25553](#), [27480](#),  
[24852](#)

## 4.8.8 The [object](#) element

Categories<sup>p113</sup>:

[Flow content](#)<sup>p115</sup>.

[Phrasing content](#)<sup>p116</sup>.

[Embedded content](#)<sup>p116</sup>.

If the element has a [usemap](#)<sup>p393</sup> attribute: [Interactive content](#)<sup>p116</sup>.

[Listed](#)<sup>p446</sup>, [submittable](#)<sup>p447</sup>, and [reassociateable](#)<sup>p447</sup> [form-associated element](#)<sup>p446</sup>.

[Palpable content](#)<sup>p117</sup>.

Contexts in which this element can be used<sup>p113</sup>:

Where [embedded content](#)<sup>p116</sup> is expected.

Content model<sup>p113</sup>:

Zero or more [param](#)<sup>p316</sup> elements, then, [transparent](#)<sup>p117</sup>.

Tag omission in text/html<sup>p113</sup>:

Neither tag is omitable.

Content attributes<sup>p113</sup>:

[Global attributes](#)<sup>p120</sup>

[data](#)<sup>p311</sup> — Address of the resource

[type](#)<sup>p311</sup> — Type of embedded resource

[typeMustMatch](#)<sup>p311</sup> — Whether the [type](#)<sup>b311</sup> attribute and the [Content-Type](#)<sup>p86</sup> value need to match for the resource to be used

[name](#)<sup>p311</sup> — Name of [nested browsing context](#)<sup>763</sup>

[usemap](#)<sup>p393</sup> — Name of [image map](#)<sup>p393</sup> to use

[form](#)<sup>p527</sup> — Associates the control with a [form](#)<sup>p447</sup> element

[width](#)<sup>p397</sup> — Horizontal dimension

[height](#)<sup>p397</sup> — Vertical dimension

DOM interface<sup>p113</sup>:

IDL	interface <b>HTMLObjectElement</b> : <a href="#">HTMLElement</a> { attribute DOMString <a href="#">data</a> ; attribute DOMString <a href="#">type</a> ; attribute boolean <a href="#">typeMustMatch</a> ; attribute DOMString <a href="#">name</a> ; attribute DOMString <a href="#">useMap</a> ; readonly attribute <a href="#">HTMLFormElement</a> ? <a href="#">form</a> ; attribute DOMString <a href="#">width</a> ; attribute DOMString <a href="#">height</a> ; readonly attribute <a href="#">Document</a> ? <a href="#">contentDocument</a> ; readonly attribute <a href="#">WindowProxy</a> ? <a href="#">contentWindow</a> ; <a href="#">Document</a> ? <a href="#">getSVGDocument</a> ();  readonly attribute boolean <a href="#">willValidate</a> ; readonly attribute <a href="#">ValidityState</a> <a href="#">validity</a> ; readonly attribute DOMString <a href="#">validationMessage</a> ; boolean <a href="#">checkValidity</a> (); boolean <a href="#">reportValidity</a> ();
-----	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

```

void setCustomValidity(DOMString error);

legacycaller any (any... arguments);

// also has obsolete members
};

```

Depending on the type of content instantiated by the object<sup>b310</sup> element, the node also supports other interfaces.

The object<sup>b310</sup> element can represent an external resource, which, depending on the type of the resource, will either be treated as an image, as a nested browsing context<sup>p763</sup>, or as an external resource to be processed by a plugin<sup>p43</sup>.

The data attribute, if present, specifies the address of the resource. If present, the attribute must be a valid non-empty URL potentially surrounded by spaces<sup>p82</sup>.

**⚠️ Warning!** *Authors who reference resources from other origins<sup>p776</sup> that they do not trust are urged to use the typemustmatch<sup>b311</sup> attribute defined below. Without that attribute, it is possible in certain cases for an attacker on the remote host to use the plugin mechanism to run arbitrary scripts, even if the author has used features such as the Flash "allowScriptAccess" parameter.*

The type attribute, if present, specifies the type of the resource. If present, the attribute must be a valid MIME type<sup>p42</sup>.

At least one of either the data<sup>b311</sup> attribute or the type<sup>b311</sup> attribute must be present.

If the itemprop<sup>p692</sup> attribute is specified on an object<sup>b310</sup> element, then the data<sup>b311</sup> attribute must also be specified.

The typemustmatch attribute is a boolean attribute<sup>p59</sup> whose presence indicates that the resource specified by the data<sup>b311</sup> attribute is only to be used if the value of the type<sup>b311</sup> attribute and the Content-Type<sup>p86</sup> of the aforementioned resource match.

The typemustmatch<sup>b311</sup> attribute must not be specified unless both the data<sup>b311</sup> attribute and the type<sup>b311</sup> attribute are present.

The name attribute, if present, must be a valid browsing context name<sup>p765</sup>. The given value is used to name the nested browsing context<sup>p763</sup>, if applicable.

Whenever one of the following conditions occur:

- the element is created,
- the element is popped off the stack of open elements<sup>p962</sup> of an HTML parser<sup>p952</sup> or XML parser<sup>p1054</sup>,
- the element is not on the stack of open elements<sup>p962</sup> of an HTML parser<sup>p952</sup> or XML parser<sup>p1054</sup>, and it is either inserted into a document<sup>p42</sup> or removed from a document<sup>p42</sup>,
- the element's node document changes whether it is fully active<sup>p763</sup>,
- one of the element's ancestor object<sup>b310</sup> elements changes to or from showing its fallback content<sup>p116</sup>,
- the element's classid<sup>p1098</sup> attribute is set, changed, or removed,
- the element's classid<sup>p1098</sup> attribute is not present, and its data<sup>b311</sup> attribute is set, changed, or removed,
- neither the element's classid<sup>p1098</sup> attribute nor its data<sup>b311</sup> attribute are present, and its type<sup>b311</sup> attribute is set, changed, or removed,
- the element changes from being rendered<sup>p1058</sup> to not being rendered, or vice versa,

...the user agent must queue a task<sup>p835</sup> to run the following steps to (re)determine what the object<sup>b310</sup> element represents. This task<sup>p834</sup> being queued<sup>p835</sup> or actively running must delay the load event<sup>p1033</sup> of the element's node document.

- If the user has indicated a preference that this [object](#)<sup>p310</sup> element's [fallback content](#)<sup>b116</sup> be shown instead of the element's usual behaviour, then jump to the step below labeled *fallback*.
- If the element has an ancestor [media element](#)<sup>p326</sup>, or has an ancestor [object](#)<sup>p310</sup> element that is *not* showing its [fallback content](#)<sup>b116</sup>, or if the element is not [in a Document](#)<sup>p42</sup> with a [browsing context](#)<sup>p762</sup>, or if the element's [node document](#) is not [fully active](#)<sup>p763</sup>, or if the element is still in the [stack of open elements](#)<sup>p962</sup> of an [HTML parser](#)<sup>p952</sup> or [XML parser](#)<sup>p1054</sup>, or if the element is not [being rendered](#)<sup>p1058</sup>, then jump to the step below labeled *fallback*.
- If the [classid](#)<sup>p1098</sup> attribute is present, and has a value that isn't the empty string, then: if the user agent can find a [plugin](#)<sup>p43</sup> suitable according to the value of the [classid](#)<sup>p1098</sup> attribute, and either [plugins aren't being sandboxed](#)<sup>p314</sup> or that [plugin](#)<sup>p43</sup> can be [secured](#)<sup>p43</sup>, then that [plugin](#)<sup>p43</sup> [should be used](#)<sup>p314</sup>, and the value of the [data](#)<sup>p311</sup> attribute, if any, should be passed to the [plugin](#)<sup>p43</sup>. If no suitable [plugin](#)<sup>p43</sup> can be found, or if the [plugin](#)<sup>p43</sup> reports an error, jump to the step below labeled *fallback*.
- If the [data](#)<sup>p311</sup> attribute is present and its value is not the empty string, then:
  - If the [type](#)<sup>p311</sup> attribute is present and its value is not a type that the user agent supports, and is not a type that the user agent can find a [plugin](#)<sup>p43</sup> for, then the user agent may jump to the step below labeled *fallback* without fetching the content to examine its real type.
  - [Resolve](#)<sup>p82</sup> the [URL](#)<sup>p48</sup> specified by the [data](#)<sup>p311</sup> attribute, relative to the element.
  - If that failed, [fire a simple event](#)<sup>p846</sup> named [error](#)<sup>p1144</sup> at the element, then jump to the step below labeled *fallback*.
  - [Fetch](#)<sup>p84</sup> the resulting [absolute URL](#)<sup>p48</sup>, from the element's [browsing context scope origin](#)<sup>p765</sup> if it has one.

Fetching the resource must [delay the load event](#)<sup>b1033</sup> of the element's [node document](#) until the [task](#)<sup>p834</sup> that is [queued](#)<sup>p835</sup> by the [networking task source](#)<sup>p839</sup> once the resource has been [fetched](#)<sup>p84</sup> (defined next) has been run.

For the purposes of the [application cache](#)<sup>p809</sup> networking model, this [fetch](#)<sup>p84</sup> operation is not for a [child browsing context](#)<sup>p763</sup> (though it might end up being used for one after all, as defined below).

- If the resource is not yet available (e.g. because the resource was not available in the cache, so that loading the resource required making a request over the network), then jump to the step below labeled *fallback*. The [task](#)<sup>p834</sup> that is [queued](#)<sup>p835</sup> by the [networking task source](#)<sup>p839</sup> once the resource is available must restart this algorithm from this step. Resources can load incrementally; user agents may opt to consider a resource "available" whenever enough data has been obtained to begin processing the resource.
- If the load failed (e.g. there was an HTTP 404 error, there was a DNS error), [fire a simple event](#)<sup>p846</sup> named [error](#)<sup>p1144</sup> at the element, then jump to the step below labeled *fallback*.

7. Determine the *resource type*, as follows:

- Let the *resource type* be unknown.
- If the [object](#)<sup>p310</sup> element has a [type](#)<sup>p311</sup> attribute and a [typemustmatch](#)<sup>p311</sup> attribute, and the resource has [associated Content-Type metadata](#)<sup>p86</sup>, and the type specified in [the resource's Content-Type metadata](#)<sup>p86</sup> is an [ASCII case-insensitive](#)<sup>p58</sup> match for the value of the element's [type](#)<sup>p311</sup> attribute, then let *resource type* be that type and jump to the step below labeled *handler*.
- If the [object](#)<sup>p310</sup> element has a [typemustmatch](#)<sup>p311</sup> attribute, jump to the step below labeled *handler*.
- If the user agent is configured to strictly obey Content-Type headers for this resource, and the resource has [associated Content-Type metadata](#)<sup>p86</sup>, then let the *resource type* be the type specified in [the resource's Content-Type metadata](#)<sup>p86</sup>, and jump to the step below labeled *handler*.

*This can introduce a vulnerability, wherein a site is trying to embed a resource that uses a particular plugin, but the remote site overrides that and instead furnishes the user agent with a resource that triggers a different plugin with different security characteristics.*

5. If there is a `type`<sup>p311</sup> attribute present on the `object`<sup>p310</sup> element, and that attribute's value is not a type that the user agent supports, but it is a type that a `plugin`<sup>p43</sup> supports, then let the `resource type` be the type specified in that `type`<sup>p311</sup> attribute, and jump to the step below labeled `handler`.

6. Run the appropriate set of steps from the following list:

↪ If the resource has [associated Content-Type metadata](#)<sup>p86</sup>

1. Let `binary` be false.
2. If the type specified in [the resource's Content-Type metadata](#)<sup>p86</sup> is "`text/plain`", and the result of applying the [rules for distinguishing if a resource is text or binary](#) to the resource is that the resource is not `text/plain`, then set `binary` to true.
3. If the type specified in [the resource's Content-Type metadata](#)<sup>p86</sup> is "`application/octet-stream`", then set `binary` to true.
4. If `binary` is false, then let the `resource type` be the type specified in [the resource's Content-Type metadata](#)<sup>p86</sup>, and jump to the step below labeled `handler`.
5. If there is a `type`<sup>p311</sup> attribute present on the `object`<sup>p310</sup> element, and its value is not `application/octet-stream`, then run the following steps:
  1. If the attribute's value is a type that a `plugin`<sup>p43</sup> supports, or the attribute's value is a type that starts with "`image/`" that is not also an [XML MIME type](#)<sup>p42</sup>, then let the `resource type` be the type specified in that `type`<sup>p311</sup> attribute.
  2. Jump to the step below labeled `handler`.

↪ Otherwise, if the resource does not have [associated Content-Type metadata](#)<sup>p86</sup>

1. If there is a `type`<sup>p311</sup> attribute present on the `object`<sup>p310</sup> element, then let the `tentative type` be the type specified in that `type`<sup>p311</sup> attribute.  
Otherwise, let `tentative type` be the [sniffed type of the resource](#).
2. If `tentative type` is not `application/octet-stream`, then let `resource type` be `tentative type` and jump to the step below labeled `handler`.
7. If applying the [URL parser](#)<sup>p48</sup> algorithm to the [URL](#)<sup>p48</sup> of the specified resource (after any redirects) results in a [parsed URL](#)<sup>p48</sup> whose `path`<sup>p48</sup> component matches a pattern that a `plugin`<sup>p43</sup> supports, then let `resource type` be the type that that plugin can handle.

**Example** For example, a plugin might say that it can handle resources with `path`<sup>p48</sup> components that end with the four character string ".swf".

**Note** It is possible for this step to finish, or for one of the substeps above to jump straight to the next step, with `resource type` still being unknown. In both cases, the next step will trigger fallback.

8. **Handler:** Handle the content as given by the first of the following cases that matches:

↪ If the `resource type` is not a type that the user agent supports, but it is a type that a `plugin`<sup>p43</sup> supports

If [plugins are being sandboxed](#)<sup>p314</sup> and the plugin that supports `resource type` cannot be [secured](#)<sup>p43</sup>, jump to the step below labeled `fallback`.

Otherwise, the user agent should [use the plugin that supports resource type](#)<sup>p314</sup> and pass the content of the resource to that `plugin`<sup>p43</sup>. If the `plugin`<sup>p43</sup> reports an error, then jump to the step below labeled `fallback`.

↪ If the `resource type` is an [XML MIME type](#)<sup>p42</sup>, or if the `resource type` does not start with "image/"

The `object`<sup>p310</sup> element must be associated with a newly created [nested browsing context](#)<sup>p763</sup>, if it does not already have one.

If the [URL](#)<sup>p48</sup> of the given resource is not [about:blank](#)<sup>p84</sup>, the element's [nested browsing context](#)<sup>p763</sup> must then be [navigated](#)<sup>p791</sup> to that resource, with [replacement enabled](#)<sup>p802</sup>, and with the `object`<sup>p310</sup> element's `node`

**Note**

The [document's browsing context](#)<sup>p762</sup> as the [source browsing context](#)<sup>p791</sup>. (The [data](#)<sup>p311</sup> attribute of the [object](#)<sup>p310</sup> element doesn't get updated if the browsing context gets further navigated to other locations.)

If the [URL](#)<sup>p48</sup> of the given resource is [about:blank](#)<sup>p84</sup>, then, instead, the user agent must [queue a task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> named [load](#)<sup>p1144</sup> at the [object](#)<sup>p310</sup> element. No [load](#)<sup>p1144</sup> event is fired at the [about:blank](#)<sup>p84</sup> document itself.

The [object](#)<sup>p310</sup> element [represents](#)<sup>p111</sup> the [nested browsing context](#)<sup>p763</sup>.

If the [name](#)<sup>p311</sup> attribute is present, the [browsing context name](#)<sup>p765</sup> must be set to the value of this attribute; otherwise, the [browsing context name](#)<sup>p765</sup> must be set to the empty string.

**Note**

In certain situations, e.g. if the resource was [fetched](#)<sup>p84</sup> from an [application cache](#)<sup>p809</sup> but it is an HTML file with a [manifest](#)<sup>p137</sup> attribute that points to a different [application cache manifest](#)<sup>p809</sup>, the [navigation](#)<sup>p791</sup> of the [browsing context](#)<sup>p762</sup> will be restarted so as to load the resource afresh from the network or a different [application cache](#)<sup>p809</sup>. Even if the resource is then found to have a different type, it is still used as part of a [nested browsing context](#)<sup>p763</sup>: only the [navigate](#)<sup>p791</sup> algorithm is restarted, not this [object](#)<sup>p310</sup> algorithm.

↪ If the *resource type* starts with "image/", and support for images has not been disabled

Apply the [image sniffing](#) rules to determine the type of the image.

The [object](#)<sup>p310</sup> element [represents](#)<sup>p111</sup> the specified image. The image is not a [nested browsing context](#)<sup>p763</sup>.

If the image cannot be rendered, e.g. because it is malformed or in an unsupported format, jump to the step below labeled *fallback*.

↪ Otherwise

The given *resource type* is not supported. Jump to the step below labeled *fallback*.

**Note**

If the previous step ended with the *resource type* being unknown, this is the case that is triggered.

9. The element's contents are not part of what the [object](#)<sup>p310</sup> element represents.
10. Abort these steps. Once the resource is completely loaded, [queue a task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> named [load](#)<sup>p1144</sup> at the element.
5. If the [data](#)<sup>p311</sup> attribute is absent but the [type](#)<sup>p311</sup> attribute is present, and the user agent can find a [plugin](#)<sup>p43</sup> suitable according to the value of the [type](#)<sup>p311</sup> attribute, and either [plugins aren't being sandboxed](#)<sup>p314</sup> or the [plugin](#)<sup>p43</sup> can be [secured](#)<sup>p43</sup>, then that [plugin](#)<sup>p43</sup> [should be used](#)<sup>p314</sup>. If these conditions cannot be met, or if the [plugin](#)<sup>p43</sup> reports an error, jump to the step below labeled *fallback*. Otherwise abort these steps; once the plugin is completely loaded, [queue a task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> named [load](#)<sup>p1144</sup> at the element.
6. *Fallback:* The [object](#)<sup>p310</sup> element [represents](#)<sup>p111</sup> the element's children, ignoring any leading [param](#)<sup>p316</sup> element children. This is the element's [fallback content](#)<sup>p116</sup>. If the element has an instantiated [plugin](#)<sup>p43</sup>, then unload it.

When the algorithm above instantiates a [plugin](#)<sup>p43</sup>, the user agent should pass to the [plugin](#)<sup>p43</sup> used the names and values of all the attributes on the element, in the order they were added to the element, with the attributes added by the parser being ordered in source order, followed by a parameter named "PARAM" whose value is null, followed by all the names and values of [parameters](#)<sup>p316</sup> given by [param](#)<sup>p316</sup> elements that are children of the [object](#)<sup>p310</sup> element, in [tree order](#)<sup>p42</sup>. If the [plugin](#)<sup>p43</sup> supports a scriptable interface, the [HTMLObjectElement](#)<sup>p310</sup> object representing the element should expose that interface. The [object](#)<sup>p310</sup> element [represents](#)<sup>p111</sup> the [plugin](#)<sup>p43</sup>. The [plugin](#)<sup>p43</sup> is not a nested [browsing context](#)<sup>p762</sup>.

Plugins are considered sandboxed for the purpose of an [object](#)<sup>p310</sup> element if the [sandboxed plugins browsing context flag](#)<sup>p780</sup> is set on the [object](#)<sup>p310</sup> element's [node document's active sandboxing flag set](#)<sup>p782</sup>.

Due to the algorithm above, the contents of [object](#)<sup>p310</sup> elements act as [fallback content](#)<sup>p116</sup>, used only when referenced resources can't be shown (e.g. because it returned a 404 error). This allows multiple [object](#)<sup>p310</sup> elements to be nested inside each other, targeting multiple user agents with different capabilities, with the user agent picking the first one it supports.

When an `object`<sup>p310</sup> element represents a `nested browsing context`<sup>p763</sup>: if the `object`<sup>p310</sup> element's `nested browsing context`<sup>p763</sup>'s `active document`<sup>p762</sup> is not `ready for post-load tasks`<sup>p1033</sup>, and when anything is `delaying the load event`<sup>p1033</sup> of the `object`<sup>p310</sup> element's `browsing context`<sup>p762</sup>'s `active document`<sup>p762</sup>, and when the `object`<sup>p310</sup> element's `browsing context`<sup>p762</sup> is in the `delaying load events mode`<sup>p763</sup>, the `object`<sup>p310</sup> must `delay the load event`<sup>p1033</sup> of its document.

The `task source`<sup>p835</sup> for the `tasks`<sup>p834</sup> mentioned in this section is the `DOM manipulation task source`<sup>p838</sup>.

Whenever the `name`<sup>b311</sup> attribute is set, if the `object`<sup>p310</sup> element has a nested `browsing context`<sup>p762</sup>, its `name`<sup>p765</sup> must be changed to the new value. If the attribute is removed, if the `object`<sup>p310</sup> element has a `browsing context`<sup>p762</sup>, the `browsing context name`<sup>p765</sup> must be set to the empty string.

The `usemap`<sup>b393</sup> attribute, if present while the `object`<sup>p310</sup> element represents an image, can indicate that the object has an associated `image map`<sup>p393</sup>. The attribute must be ignored if the `object`<sup>p310</sup> element doesn't represent an image.

The `form`<sup>p527</sup> attribute is used to explicitly associate the `object`<sup>p310</sup> element with its `form owner`<sup>p527</sup>.

**Constraint validation:** `object`<sup>p310</sup> elements are always `barred from constraint validation`<sup>p553</sup>.

The `object`<sup>p310</sup> element supports `dimension attributes`<sup>p397</sup>.

The IDL attributes `data`, `type` and `name` each must `reflect`<sup>p88</sup> the respective content attributes of the same name. The `typeMustMatch` IDL attribute must `reflect`<sup>p88</sup> the `typemustmatch`<sup>b311</sup> content attribute. The `useMap` IDL attribute must `reflect`<sup>p88</sup> the `usemap`<sup>b393</sup> content attribute.

The `contentDocument` IDL attribute must return the `Document`<sup>p102</sup> object of the `active document`<sup>p762</sup> of the `object`<sup>p310</sup> element's `nested browsing context`<sup>p763</sup>, if any and if its `effective script origin`<sup>b776</sup> is the `same origin`<sup>p778</sup> as the `effective script origin`<sup>p776</sup> specified by the `incumbent settings object`<sup>p831</sup>, or null otherwise.

The `contentWindow` IDL attribute must return the `WindowProxy`<sup>p775</sup> object of the `object`<sup>p310</sup> element's `nested browsing context`<sup>p763</sup>, if it has one; otherwise, it must return null.

The `willValidate`<sup>p555</sup>, `validity`<sup>b556</sup>, and `validationMessage`<sup>p557</sup> attributes, and the `checkValidity()`<sup>p556</sup>, `reportValidity()`<sup>p557</sup>, and `setCustomValidity()`<sup>p555</sup> methods, are part of the `constraint validation API`<sup>p554</sup>. The `form`<sup>p529</sup> IDL attribute is part of the element's forms API.

All `object`<sup>p310</sup> elements have a **legacy caller operation**. If the `object`<sup>p310</sup> element has an instantiated `plugin`<sup>p43</sup> that supports a scriptable interface that defines a legacy caller operation, then that must be the behaviour of the object's legacy caller operation. Otherwise, the object's legacy caller operation must be to throw a `NotSupportedError`<sup>p50</sup> exception.

### Example

In the following example, a Java applet is embedded in a page using the `object`<sup>p310</sup> element. (Generally speaking, it is better to avoid using applets like these and instead use native JavaScript and HTML to provide the functionality, since that way the application will work on all Web browsers without requiring a third-party plugin. Many devices, especially embedded devices, do not support third-party technologies like Java.)

```
<figure>
<object type="application/x-java-applet">
 <param name="code" value="MyJavaClass">
 <p>You do not have Java available, or it is disabled.</p>
</object>
<figcaption>My Java Clock</figcaption>
</figure>
```

### Example

In this example, an HTML page is embedded in another using the `object`<sup>p310</sup> element.

```
<figure>
<object data="clock.html"></object>
<figcaption>My HTML Clock</figcaption>
</figure>
```

### Example

The following example shows how a plugin can be used in HTML (in this case the Flash plugin, to show a video file). Fallback is provided for users who do not have Flash enabled, in this case using the `video`<sup>p317</sup> element to show the video for those using user

agents that support [video](#)<sup>p317</sup>, and finally providing a link to the video for those who have neither Flash nor a [video](#)<sup>p317</sup>-capable browser.

```
<p>Look at my video:
<object type="application/x-shockwave-flash">
 <param name=movie value="http://video.example.com/library/watch.swf">
 <param name=allowfullscreen value=true>
 <param name=flashvars value="http://video.example.com/vids/315981">
 <video controls src="http://video.example.com/vids/315981">
 View video.
 </video>
</object>
</p>
```

#### 4.8.9 The **param** element

**Categories**<sup>p113</sup>:

None.

**Contexts in which this element can be used**<sup>p113</sup>:

As a child of an [object](#)<sup>p310</sup> element, before any [flow content](#)<sup>p115</sup>.

**Content model**<sup>p113</sup>:

[Nothing](#)<sup>p114</sup>.

**Tag omission in text/html**<sup>p113</sup>:

No [end tag](#)<sup>p944</sup>.

**Content attributes**<sup>p113</sup>:

[Global attributes](#)<sup>p120</sup>

[name](#)<sup>p316</sup> — Name of parameter

[value](#)<sup>p316</sup> — Value of parameter

**DOM interface**<sup>p113</sup>:

```
IDL
interface HTMLParamElement : HTMLElement {
 attribute DOMString name;
 attribute DOMString value;

 // also has obsolete members
};
```

The [param](#)<sup>p316</sup> element defines parameters for plugins invoked by [object](#)<sup>p310</sup> elements. It does not [represent](#)<sup>p111</sup> anything on its own.

The [name](#) attribute gives the name of the parameter.

The [value](#) attribute gives the value of the parameter.

Both attributes must be present. They may have any value.

If both attributes are present, and if the parent element of the [param](#)<sup>p316</sup> is an [object](#)<sup>p310</sup> element, then the element defines a **parameter** with the given name-value pair.

If either the name or value of a [parameter](#)<sup>p316</sup> defined by a [param](#)<sup>p316</sup> element that is the child of an [object](#)<sup>p310</sup> element that [represents](#)<sup>p111</sup> an instantiated [plugin](#)<sup>p43</sup> changes, and if that [plugin](#)<sup>p43</sup> is communicating with the user agent using an API that features the ability to update the [plugin](#)<sup>p43</sup> when the name or value of a [parameter](#)<sup>p316</sup> so changes, then the user agent must appropriately exercise that ability to notify the [plugin](#)<sup>p43</sup> of the change.

The IDL attributes [name](#) and [value](#) must both [reflect](#)<sup>p88</sup> the respective content attributes of the same name.

**Example**

The following example shows how the `param`<sup>p316</sup> element can be used to pass a parameter to a plugin, in this case the O3D plugin.

```
<!DOCTYPE HTML>
<html lang="en">
 <head>
 <title>O3D Utah Teapot</title>
 </head>
 <body>
 <p>
 <object type="application/vnd.o3d.auto">
 <param name="o3d_features" value="FloatingPointTextures">

 <p>To see the teapot actually rendered by O3D on your
 computer, please download and install the O3D plugin.</p>
 </object>
 <script src="o3d-teapot.js"></script>
 </p>
 </body>
</html>
```

#### 4.8.10 The `video` element

**Categories**<sup>p113</sup>:

[Flow content](#)<sup>p115</sup>.

[Phrasing content](#)<sup>p116</sup>.

[Embedded content](#)<sup>p116</sup>.

If the element has a [controls](#)<sup>p382</sup> attribute: [Interactive content](#)<sup>p116</sup>.

[Palpable content](#)<sup>p117</sup>.

**Contexts in which this element can be used**<sup>p113</sup>:

Where [embedded content](#)<sup>p116</sup> is expected.

**Content model**<sup>p113</sup>:

If the element has a [src](#)<sup>p329</sup> attribute: zero or more [track](#)<sup>p324</sup> elements, then [transparent](#)<sup>p117</sup>, but with no [media element](#)<sup>p326</sup> descendants.

If the element does not have a [src](#)<sup>p329</sup> attribute: zero or more [source](#)<sup>p322</sup> elements, then zero or more [track](#)<sup>p324</sup> elements, then [transparent](#)<sup>p117</sup>, but with no [media element](#)<sup>p326</sup> descendants.

**Tag omission in text/html**<sup>p113</sup>:

Neither tag is ommissible.

**Content attributes**<sup>p113</sup>:

[Global attributes](#)<sup>p120</sup>

[src](#)<sup>p329</sup> — Address of the resource

[crossorigin](#)<sup>p329</sup> — How the element handles crossorigin requests

[poster](#)<sup>p318</sup> — Poster frame to show prior to video playback

[preload](#)<sup>p340</sup> — Hints how much buffering the [media resource](#)<sup>p328</sup> will likely need

[autoplay](#)<sup>p345</sup> — Hint that the [media resource](#)<sup>p328</sup> can be started automatically when the page is loaded

[mediagroup](#)<sup>p364</sup> — Groups [media elements](#)<sup>p326</sup> together with an implicit [MediaController](#)<sup>p358</sup>

[loop](#)<sup>p343</sup> — Whether to loop the [media resource](#)<sup>p328</sup>

[muted](#)<sup>p384</sup> — Whether to mute the [media resource](#)<sup>p328</sup> by default

[controls](#)<sup>p382</sup> — Show user agent controls

[width](#)<sup>p397</sup> — Horizontal dimension

Support:	
Chrome	4+
IE	9+
Chrome for Android	40+
Firefox	3.5+
iOS Safari	3.2+
Android Browser	2.3+
UC Browser for Android	9.9+
Opera Mini	None
Safari	4+
Opera	10.5+
IE Mobile	10+
Firefox for Android	33+

Source: [caniuse.com](http://caniuse.com)

height<sup>p397</sup> — Vertical dimension

DOM interface<sup>p113</sup>:

```
IDL interface HTMLVideoElement : HTMLMediaElement {
 attribute unsigned long width;
 attribute unsigned long height;
 readonly attribute unsigned long videoWidth;
 readonly attribute unsigned long videoHeight;
 attribute DOMString poster;
};
```

A video<sup>p317</sup> element is used for playing videos or movies, and audio files with captions.

Content may be provided inside the video<sup>p317</sup> element. User agents should not show this content to the user; it is intended for older Web browsers which do not support video<sup>p317</sup>, so that legacy video plugins can be tried, or to show text to the users of these older browsers informing them of how to access the video contents.

**Note** *In particular, this content is not intended to address accessibility concerns. To make video content accessible to the partially sighted, the blind, the hard-of-hearing, the deaf, and those with other physical or cognitive disabilities, a variety of features are available. Captions can be provided, either embedded in the video stream or as external files using the track<sup>p324</sup> element. Sign-language tracks can be provided, again either embedded in the video stream or by synchronising multiple video<sup>p317</sup> elements using the mediagroup<sup>p364</sup> attribute or a MediaController<sup>p358</sup> object. Audio descriptions can be provided, either as a separate track embedded in the video stream, or a separate audio track in an audio<sup>p321</sup> element slaved<sup>p360</sup> to the same controller as the video<sup>p317</sup> element(s), or in text form using a WebVTT file<sup>b54</sup> referenced using the track<sup>p324</sup> element and synthesized into speech by the user agent. WebVTT can also be used to provide chapter titles. For users who would rather not use a media element at all, transcripts or other textual alternatives can be provided by simply linking to them in the prose near the video<sup>p317</sup> element. [WEBVTT]<sup>p1154</sup>*

The video<sup>p317</sup> element is a media element<sup>p326</sup> whose media data<sup>p328</sup> is ostensibly video data, possibly with associated audio data.

The src<sup>p329</sup>, preload<sup>b340</sup>, autoplay<sup>p345</sup>, mediagroup<sup>p364</sup>, loop<sup>p343</sup>, muted<sup>p384</sup>, and controls<sup>p382</sup> attributes are the attributes common to all media elements<sup>p328</sup>.

The poster attribute gives the address of an image file that the user agent can show while no video data is available. The attribute, if present, must contain a valid non-empty URL potentially surrounded by spaces<sup>p82</sup>.

If the specified resource is to be used, then, when the element is created or when the poster<sup>p318</sup> attribute is set, changed, or removed, the user agent must run the following steps to determine the element's **poster frame** (regardless of the value of the element's show poster flag<sup>p342</sup>):

1. If there is an existing instance of this algorithm running for this video<sup>p317</sup> element, abort that instance of this algorithm without changing the poster frame<sup>p318</sup>.
2. If the poster<sup>p318</sup> attribute's value is the empty string or if the attribute is absent, then there is no poster frame<sup>p318</sup>; abort these steps.
3. Resolve<sup>p82</sup> the poster<sup>p318</sup> attribute's value relative to the element. If this fails, then there is no poster frame<sup>p318</sup>; abort these steps.
4. Fetch<sup>p84</sup> the resulting absolute URL<sup>p48</sup>, from the element's node document's origin<sup>b776</sup>. This must delay the load event<sup>p1033</sup> of the element's node document.
5. If an image is thus obtained, the poster frame<sup>p318</sup> is that image. Otherwise, there is no poster frame<sup>p318</sup>.

**Note** *The image given by the poster<sup>p318</sup> attribute, the poster frame<sup>p318</sup>, is intended to be a representative frame of the video (typically one of the first non-blank frames) that gives the user an idea of what the video is like.*

A video<sup>p317</sup> element represents what is given for the first matching condition in the list below:

- ↪ When no video data is available (the element's readyState<sup>p345</sup> attribute is either HAVE NOTHING<sup>b343</sup>, or HAVE METADATA<sup>p343</sup> but no video data has yet been obtained at all, or the element's readyState<sup>p345</sup> attribute is any subsequent value but the media resource<sup>p328</sup> does not have a video channel)

The video<sup>p317</sup> element represents<sup>p111</sup> its poster frame<sup>p318</sup>, if any, or else transparent black with no intrinsic dimensions.

- ↪ When the `video`<sup>p317</sup> element is `paused`<sup>p346</sup>, the `current playback position`<sup>p342</sup> is the first frame of video, and the element's `show poster flag`<sup>p342</sup> is set
  - The `video`<sup>p317</sup> element `represents`<sup>p111</sup> its `poster frame`<sup>p318</sup>, if any, or else the first frame of the video.
- ↪ When the `video`<sup>p317</sup> element is `paused`<sup>p346</sup>, and the frame of video corresponding to the `current playback position`<sup>p342</sup> is not available (e.g. because the video is seeking or buffering)
- ↪ When the `video`<sup>p317</sup> element is neither `potentially playing`<sup>p346</sup> nor `paused`<sup>p346</sup> (e.g. when seeking or stalled)
  - The `video`<sup>p317</sup> element `represents`<sup>p111</sup> the last frame of the video to have been rendered.
- ↪ When the `video`<sup>p317</sup> element is `paused`<sup>p346</sup>
  - The `video`<sup>p317</sup> element `represents`<sup>p111</sup> the frame of video corresponding to the `current playback position`<sup>p342</sup>.
- ↪ Otherwise (the `video`<sup>p317</sup> element has a video channel and is `potentially playing`<sup>p346</sup>)
  - The `video`<sup>p317</sup> element `represents`<sup>p111</sup> the frame of video at the continuously increasing "`current`" position<sup>p342</sup>. When the `current playback position`<sup>p342</sup> changes such that the last frame rendered is no longer the frame corresponding to the `current playback position`<sup>p342</sup> in the video, the new frame must be rendered.

Frames of video must be obtained from the video track that was `selected`<sup>p357</sup> when the `event loop`<sup>p834</sup> last reached `step 1`<sup>p836</sup>.

**Note** Which frame in a video stream corresponds to a particular playback position is defined by the video stream's format.

The `video`<sup>p317</sup> element also `represents`<sup>p111</sup> any `text track cues`<sup>p368</sup> whose `text track cue active flag`<sup>p368</sup> is set and whose `text track`<sup>p365</sup> is in the `showing`<sup>p367</sup> mode, and any audio from the `media resource`<sup>p328</sup>, at the `current playback position`<sup>p342</sup>.

Any audio associated with the `media resource`<sup>p328</sup> must, if played, be played synchronised with the `current playback position`<sup>p342</sup>, at the element's `effective media volume`<sup>p384</sup>. The user agent must play the audio from audio tracks that were `enabled`<sup>p357</sup> when the `event loop`<sup>p834</sup> last reached step 1.

In addition to the above, the user agent may provide messages to the user (such as "buffering", "no video loaded", "error", or more detailed information) by overlaying text or icons on the video or other areas of the element's playback area, or in another appropriate manner.

User agents that cannot render the video may instead make the element `represent`<sup>p111</sup> a link to an external video playback utility or to the video data itself.

When a `video`<sup>p317</sup> element's `media resource`<sup>p328</sup> has a video channel, the element `provides a paint source`<sup>p53</sup> whose width is the `media resource`<sup>p328</sup>'s `intrinsic width`<sup>p319</sup>, whose height is the `media resource`<sup>p328</sup>'s `intrinsic height`<sup>p319</sup>, and whose appearance is the frame of video corresponding to the `current playback position`<sup>p342</sup>, if that is available, or else (e.g. when the video is seeking or buffering) its previous appearance, if any, or else (e.g. because the video is still loading the first frame) blackness.

**Note**

`video.videoWidth`<sup>p319</sup>  
`video.videoHeight`<sup>p319</sup>

These attributes return the intrinsic dimensions of the video, or zero if the dimensions are not known.

The **intrinsic width** and **intrinsic height** of the `media resource`<sup>p328</sup> are the dimensions of the resource in CSS pixels after taking into account the resource's dimensions, aspect ratio, clean aperture, resolution, and so forth, as defined for the format used by the resource. If an anamorphic format does not define how to apply the aspect ratio to the video data's dimensions to obtain the "correct" dimensions, then the user agent must apply the ratio by increasing one dimension and leaving the other unchanged.

The `videoWidth` IDL attribute must return the `intrinsic width`<sup>p319</sup> of the video in CSS pixels. The `videoHeight` IDL attribute must return the `intrinsic height`<sup>p319</sup> of the video in CSS pixels. If the element's `readyState`<sup>p345</sup> attribute is `HAVE NOTHING`<sup>p343</sup>, then the attributes must return 0.

Whenever the `intrinsic width`<sup>p319</sup> or `intrinsic height`<sup>p319</sup> of the video changes (including, for example, because the `selected video track`<sup>p357</sup> was changed), if the element's `readyState`<sup>p345</sup> attribute is not `HAVE NOTHING`<sup>p343</sup>, the user agent must `queue a task`<sup>p835</sup> to `fire a simple event`<sup>p846</sup> named `resize`<sup>p387</sup> at the `media element`<sup>p326</sup>.

The `video`<sup>p317</sup> element supports `dimension attributes`<sup>p397</sup>.

In the absence of style rules to the contrary, video content should be rendered inside the element's playback area such that the video content is shown centered in the playback area at the largest possible size that fits completely within it, with the video content's aspect ratio being preserved.

Thus, if the aspect ratio of the playback area does not match the aspect ratio of the video, the video will be shown letterboxed or pillarboxed. Areas of the element's playback area that do not contain the video represent nothing.

**Note** In user agents that implement CSS, the above requirement can be implemented by using the [style rule suggested in the rendering section](#)<sup>p1079</sup>.

The intrinsic width of a [video](#)<sup>p317</sup> element's playback area is the intrinsic width of the [poster frame](#)<sup>p318</sup>, if that is available and the element currently [represents](#)<sup>p111</sup> its poster frame; otherwise, it is the [intrinsic width](#)<sup>p319</sup> of the video resource, if that is available; otherwise the intrinsic width is missing.

The intrinsic height of a [video](#)<sup>p317</sup> element's playback area is the intrinsic height of the [poster frame](#)<sup>p318</sup>, if that is available and the element currently [represents](#)<sup>p111</sup> its poster frame; otherwise it is the [intrinsic height](#)<sup>p319</sup> of the video resource, if that is available; otherwise the intrinsic height is missing.

The [default object size](#)<sup>p53</sup> is a width of 300 CSS pixels and a height of 150 CSS pixels. [\[CSSIMAGES\]](#)<sup>p1149</sup>

User agents should provide controls to enable or disable the display of closed captions, audio description tracks, and other additional data associated with the video stream, though such features should, again, not interfere with the page's normal rendering.

User agents may allow users to view the video content in manners more suitable to the user (e.g. full-screen or in an independent resizable window). As for the other user interface features, controls to enable this should not interfere with the page's normal rendering unless the user agent is [exposing a user interface](#)<sup>p382</sup>. In such an independent context, however, user agents may make full user interfaces visible, with, e.g., play, pause, seeking, and volume controls, even if the [controls](#)<sup>p382</sup> attribute is absent.

User agents may allow video playback to affect system features that could interfere with the user's experience; for example, user agents could disable screensavers while video playback is in progress.

The [poster](#) IDL attribute must [reflect](#)<sup>p88</sup> the [poster](#)<sup>p318</sup> content attribute.

#### Example

This example shows how to detect when a video has failed to play correctly:

```
<script>
 function failed(e) {
 // video playback failed - show a message saying why
 switch (e.target.error.code) {
 case e.target.error.MEDIA_ERR_ABORTED:
 alert('You aborted the video playback.');
 break;
 case e.target.error.MEDIA_ERR_NETWORK:
 alert('A network error caused the video download to fail part-way.');
 break;
 case e.target.error.MEDIA_ERR_DECODE:
 alert('The video playback was aborted due to a corruption problem or because the video
used features your browser did not support.');
 break;
 case e.target.error.MEDIA_ERR_SRC_NOT_SUPPORTED:
 alert('The video could not be loaded, either because the server or network failed or
because the format is not supported.');
 break;
 default:
 alert('An unknown error occurred.');
 break;
 }
 }
</script>
<p><video src="tgif.vid" autoplay controls onerror="failed(event)"></video></p>
<p>Download the video file.</p>
```

## 4.8.11 The `audio` element

Spec bugs: <a href="#">7253</a>	
Support:	
Chrome	4+
IE	9+
Chrome for Android	40+
Firefox	3.5+
iOS Safari	4.0-4.1+
Android Browser	2.3+
UC Browser for Android	9.9+
Opera Mini	None
Safari	4+
Opera	10.5+
IE Mobile	10+
Firefox for Android	33+

Source: [caniuse.com](#)

### Categories<sup>p113</sup>:

[Flow content](#)<sup>p115</sup>.

[Phrasing content](#)<sup>p116</sup>.

[Embedded content](#)<sup>p116</sup>.

If the element has a [controls](#)<sup>p382</sup> attribute: [Interactive content](#)<sup>p116</sup>.

If the element has a [controls](#)<sup>p382</sup> attribute: [Palpable content](#)<sup>p117</sup>.

### Contexts in which this element can be used<sup>p113</sup>:

Where [embedded content](#)<sup>p116</sup> is expected.

### Content model<sup>p113</sup>:

If the element has a [src](#)<sup>p329</sup> attribute: zero or more [track](#)<sup>p324</sup> elements, then [transparent](#)<sup>p117</sup>, but with no [media element](#)<sup>p326</sup> descendants.

If the element does not have a [src](#)<sup>p329</sup> attribute: zero or more [source](#)<sup>p322</sup> elements, then zero or more [track](#)<sup>p324</sup> elements, then [transparent](#)<sup>p117</sup>, but with no [media element](#)<sup>p326</sup> descendants.

### Tag omission in text/html<sup>p113</sup>:

Neither tag is omissible.

### Content attributes<sup>p113</sup>:

#### [Global attributes](#)<sup>p120</sup>

[src](#)<sup>p329</sup> — Address of the resource

[crossorigin](#)<sup>p329</sup> — How the element handles crossorigin requests

[preload](#)<sup>p340</sup> — Hints how much buffering the [media resource](#)<sup>p328</sup> will likely need

[autoplay](#)<sup>p345</sup> — Hint that the [media resource](#)<sup>p328</sup> can be started automatically when the page is loaded

[mediagroup](#)<sup>p364</sup> — Groups [media elements](#)<sup>p326</sup> together with an implicit [MediaController](#)<sup>p358</sup>

[loop](#)<sup>p343</sup> — Whether to loop the [media resource](#)<sup>p328</sup>

[muted](#)<sup>p384</sup> — Whether to mute the [media resource](#)<sup>p328</sup> by default

[controls](#)<sup>p382</sup> — Show user agent controls

### DOM interface<sup>p113</sup>:

```
IDL [NamedConstructor=Audio(optional DOMString src)]
interface HTMLAudioElement : HTMLMediaElement {};
```

An [audio](#)<sup>p321</sup> element [represents](#)<sup>p111</sup> a sound or audio stream.

Content may be provided inside the [audio](#)<sup>p321</sup> element. User agents should not show this content to the user; it is intended for older Web browsers which do not support [audio](#)<sup>p321</sup>, so that legacy audio plugins can be tried, or to show text to the users of these older browsers informing them of how to access the audio contents.

**Note** *In particular, this content is not intended to address accessibility concerns. To make audio content accessible to the deaf or to those with other physical or cognitive disabilities, a variety of features are available. If captions or a sign language video are available, the [video](#)<sup>p317</sup> element can be used instead of the [audio](#)<sup>p321</sup> element to play the audio, allowing users to enable the visual alternatives. Chapter titles can be provided to aid navigation, using the [track](#)<sup>p324</sup> element and a [WebVTT file](#)<sup>p54</sup>. And, naturally, transcripts or other textual alternatives can be provided by simply linking to them in the prose near the [audio](#)<sup>p321</sup> element. [WEBVTT]<sup>p1154</sup>*

The [audio](#)<sup>p321</sup> element is a [media element](#)<sup>p326</sup> whose [media data](#)<sup>p328</sup> is ostensibly audio data.

The [src](#)<sup>p329</sup>, [preload](#)<sup>p340</sup>, [autoplay](#)<sup>p345</sup>, [mediagroup](#)<sup>p364</sup>, [loop](#)<sup>p343</sup>, [muted](#)<sup>p384</sup>, and [controls](#)<sup>p382</sup> attributes are [the attributes common to all media elements](#)<sup>p328</sup>.

When an [audio](#)<sup>p321</sup> element is [potentially playing](#)<sup>p346</sup>, it must have its audio data played synchronised with the [current playback position](#)<sup>p342</sup>, at the element's [effective media volume](#)<sup>p384</sup>. The user agent must play the audio from audio tracks that were enabled when the [event loop](#)<sup>p834</sup> last reached [step 1](#)<sup>p836</sup>.

When an [audio](#)<sup>p321</sup> element is not [potentially playing](#)<sup>p346</sup>, audio must not play for the element.

**Note**

`audio = new Audio([url])`

Returns a new `audio` element, with the `src` attribute set to the value passed in the argument, if applicable.

A constructor is provided for creating `HTMLAudioElement` objects (in addition to the factory methods from DOM such as `createElement()`): `Audio(src)`. When invoked as a constructor, it must return a new `HTMLAudioElement` object (a new `audio` element). The element must be created with its `preload` attribute set to the literal value "`auto`". If the `src` argument is present, the object created must be created with its `src` content attribute set to the provided value (this will cause the user agent to invoke the object's `resource selection algorithm` before returning). The element's `node document` must be the `active document` of the `browsing context` of the `Window` object on which the interface object of the invoked constructor is found.

#### 4.8.12 The `source` element

Spec bugs: 26690

**Categories**<sup>p113</sup>:

None.

**Contexts in which this element can be used**<sup>p113</sup>:

As a child of a `media element`, before any `flow content` or `track` elements.

**Content model**<sup>p113</sup>:

Nothing<sup>p114</sup>.

**Tag omission in text/html**<sup>p113</sup>:

No end tag<sup>p944</sup>.

**Content attributes**<sup>p113</sup>:

Global attributes<sup>p120</sup>

`src` — Address of the resource

`type` — Type of embedded resource

**DOM interface**<sup>p113</sup>:

```
IDL
interface HTMLSourceElement : HTMLElement {
 attribute DOMString src;
 attribute DOMString type;

 // also has obsolete members
};
```

The `source` element allows authors to specify multiple alternative `media resources` for `media elements`. It does not `represent` anything on its own.

The `src` attribute gives the address of the `media resource`. The value must be a `valid non-empty URL potentially surrounded by spaces`. This attribute must be present.

**Note**

Dynamically modifying a `source` element and its attribute when the element is already inserted in a `video` or `audio` element will have no effect. To change what is playing, just use the `src` attribute on the `media element` directly, possibly making use of the `canPlayType()` method to pick from amongst available resources. Generally, manipulating `source` elements manually after the document has been parsed is an unnecessarily complicated approach.

The `type` attribute gives the type of the `media resource`, to help the user agent determine if it can play this `media resource` before fetching it. If specified, its value must be a `valid MIME type`. The `codecs` parameter, which certain MIME types define, might be necessary to specify exactly how the resource is encoded. [RFC6381]<sup>p1153</sup>

**Example**

The following list shows some examples of how to use the `codecs` parameter in the `type` attribute.

## H.264 Constrained baseline profile video (main and extended video compatible) level 3 and Low-Complexity AAC audio in MP4 container

```
<source src='video.mp4' type='video/mp4; codecs="avc1.42E01E, mp4a.40.2"'>
```

## H.264 Extended profile video (baseline-compatible) level 3 and Low-Complexity AAC audio in MP4 container

```
<source src='video.mp4' type='video/mp4; codecs="avc1.58A01E, mp4a.40.2"'>
```

## H.264 Main profile video level 3 and Low-Complexity AAC audio in MP4 container

```
<source src='video.mp4' type='video/mp4; codecs="avc1.4D401E, mp4a.40.2"'>
```

## H.264 'High' profile video (incompatible with main, baseline, or extended profiles) level 3 and Low-Complexity AAC audio in MP4 container

```
<source src='video.mp4' type='video/mp4; codecs="avc1.64001E, mp4a.40.2"'>
```

## MPEG-4 Visual Simple Profile Level 0 video and Low-Complexity AAC audio in MP4 container

```
<source src='video.mp4' type='video/mp4; codecs="mp4v.20.8, mp4a.40.2"'>
```

## MPEG-4 Advanced Simple Profile Level 0 video and Low-Complexity AAC audio in MP4 container

```
<source src='video.mp4' type='video/mp4; codecs="mp4v.20.240, mp4a.40.2"'>
```

## MPEG-4 Visual Simple Profile Level 0 video and AMR audio in 3GPP container

```
<source src='video.3gp' type='video/3gpp; codecs="mp4v.20.8, samr"'>
```

## Theora video and Vorbis audio in Ogg container

```
<source src='video.ogv' type='video/ogg; codecs="theora, vorbis"'>
```

## Theora video and Speex audio in Ogg container

```
<source src='video.ogv' type='video/ogg; codecs="theora, speex"'>
```

## Vorbis audio alone in Ogg container

```
<source src='audio.ogg' type='audio/ogg; codecs=vorbis'>
```

## Speex audio alone in Ogg container

```
<source src='audio.spx' type='audio/ogg; codecs=speex'>
```

## FLAC audio alone in Ogg container

```
<source src='audio.oga' type='audio/ogg; codecs=flac'>
```

## Dirac video and Vorbis audio in Ogg container

```
<source src='video.ogv' type='video/ogg; codecs="dirac, vorbis"'>
```

If a [source<sup>p322</sup>](#) element is inserted<sup>p43</sup> as a child of a [media element<sup>p326</sup>](#) that has no [src<sup>p329</sup>](#) attribute and whose [networkState<sup>p331</sup>](#) has the value [NETWORK\\_EMPTY<sup>p331</sup>](#), the user agent must invoke the [media element<sup>p326</sup>](#)'s [resource selection algorithm<sup>p332</sup>](#).

The IDL attributes [src](#) and [type](#) must [reflect<sup>b88</sup>](#) the respective content attributes of the same name.

### Example

If the author isn't sure if user agents will all be able to render the media resources provided, the author can listen to the [error<sup>p1144</sup>](#) event on the last [source<sup>p322</sup>](#) element and trigger fallback behaviour:

```
<script>
function fallback(video) {
 // replace <video> with its contents
 while (video.hasChildNodes()) {
```

```

 if (video.firstChild instanceof HTMLSourceElement)
 video.removeChild(video.firstChild);
 else
 video.parentNode.insertBefore(video.firstChild, video);
 }
 video.parentNode.removeChild(video);
}
</script>
<video controls autoplay>
 <source src='video.mp4' type='video/mp4; codecs="avc1.42E01E, mp4a.40.2"'>
 <source src='video.ogv' type='video/ogg; codecs="theora, vorbis"' onerror="fallback(parentNode)">
 ...
</video>

```

#### 4.8.13 The **track** element

**Categories**<sup>p113</sup>:

None.

**Contexts in which this element can be used**<sup>p113</sup>:

As a child of a [media element](#)<sup>p326</sup>, before any [flow content](#)<sup>p115</sup>.

**Content model**<sup>p113</sup>:

[Nothing](#)<sup>p114</sup>.

**Tag omission in text/html**<sup>p113</sup>:

No [end tag](#)<sup>p944</sup>.

**Content attributes**<sup>p113</sup>:

[Global attributes](#)<sup>p120</sup>

[kind](#)<sup>p325</sup> — The type of text track

[src](#)<sup>p325</sup> — Address of the resource

[srclang](#)<sup>p325</sup> — Language of the text track

[label](#)<sup>p325</sup> — User-visible label

[default](#)<sup>p325</sup> — Enable the track if no other [text track](#)<sup>p365</sup> is more suitable

**DOM interface**<sup>p113</sup>:

IDL	<pre> interface HTMLTrackElement : HTMLElement {     attribute DOMString kind;     attribute DOMString src;     attribute DOMString srclang;     attribute DOMString label;     attribute boolean default;      const unsigned short NONE = 0;     const unsigned short LOADING = 1;     const unsigned short LOADED = 2;     const unsigned short ERROR = 3;     readonly attribute unsigned short readyState;      readonly attribute TextTrack track; }; </pre>
-----	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

The [track](#)<sup>p324</sup> element allows authors to specify explicit external timed [text tracks](#)<sup>p365</sup> for [media elements](#)<sup>p326</sup>. It does not [represent](#)<sup>p111</sup> anything on its own.

The `kind` attribute is an [enumerated attribute<sup>p60</sup>](#). The following table lists the keywords defined for this attribute. The keyword given in the first cell of each row maps to the state given in the second cell.

Keyword	State	Brief description
<code>subtitles</code>	<code>Subtitles</code>	Transcription or translation of the dialogue, suitable for when the sound is available but not understood (e.g. because the user does not understand the language of the <a href="#">media resource<sup>p328</sup></a> 's audio track). Overlaid on the video.
<code>captions</code>	<code>Captions</code>	Transcription or translation of the dialogue, sound effects, relevant musical cues, and other relevant audio information, suitable for when sound is unavailable or not clearly audible (e.g. because it is muted, drowned-out by ambient noise, or because the user is deaf). Overlaid on the video; labeled as appropriate for the hard-of-hearing.
<code>descriptions</code>	<code>Descriptions</code>	Textual descriptions of the video component of the <a href="#">media resource<sup>p328</sup></a> , intended for audio synthesis when the visual component is obscured, unavailable, or not usable (e.g. because the user is interacting with the application without a screen while driving, or because the user is blind). Synthesized as audio.
<code>chapters</code>	<code>Chapters</code>	Chapter titles, intended to be used for navigating the <a href="#">media resource<sup>p328</sup></a> . Displayed as an interactive (potentially nested) list in the user agent's interface.
<code>metadata</code>	<code>Metadata</code>	Tracks intended for use from script. Not displayed by the user agent.

The attribute may be omitted. The [missing value default<sup>p60</sup>](#) is the [subtitles<sup>p325</sup>](#) state.

The `src` attribute gives the address of the text track data. The value must be a [valid non-empty URL potentially surrounded by spaces<sup>p82</sup>](#). This attribute must be present.

If the element has a [src<sup>p325</sup>](#) attribute whose value is not the empty string and whose value, when the attribute was set, could be successfully [resolved<sup>p82</sup>](#) relative to the element, then the element's `track URL` is the resulting [absolute URL<sup>p48</sup>](#). Otherwise, the element's [track URL<sup>p325</sup>](#) is the empty string.

If the element's [track URL<sup>p325</sup>](#) identifies a WebVTT resource, and the element's [kind<sup>p325</sup>](#) attribute is not in the [metadata<sup>p325</sup>](#) state, then the WebVTT file must be a [WebVTT file using cue text<sup>p54</sup>](#). [\[WEBVTT\]<sup>p1154</sup>](#)

Furthermore, if the element's [track URL<sup>p325</sup>](#) identifies a WebVTT resource, and the element's [kind<sup>p325</sup>](#) attribute is in the [chapters<sup>p325</sup>](#) state, then the WebVTT file must be both a [WebVTT file using chapter title text<sup>p54</sup>](#) and a [WebVTT file using only nested cues<sup>p54</sup>](#). [\[WEBVTT\]<sup>p1154</sup>](#)

The `srclang` attribute gives the language of the text track data. The value must be a valid BCP 47 language tag. This attribute must be present if the element's [kind<sup>p325</sup>](#) attribute is in the [subtitles<sup>p325</sup>](#) state. [\[BCP47\]<sup>p1148</sup>](#)

If the element has a [srclang<sup>p325</sup>](#) attribute whose value is not the empty string, then the element's `track language` is the value of the attribute. Otherwise, the element has no [track language<sup>p325</sup>](#).

The `label` attribute gives a user-readable title for the track. This title is used by user agents when listing [subtitle<sup>p325</sup>](#), [caption<sup>p325</sup>](#), and [audio description<sup>p325</sup>](#) tracks in their user interface.

The value of the [label<sup>p325</sup>](#) attribute, if the attribute is present, must not be the empty string. Furthermore, there must not be two [track<sup>p324</sup>](#) element children of the same [media element<sup>p326</sup>](#) whose [kind<sup>p325</sup>](#) attributes are in the same state, whose [srclang<sup>p325</sup>](#) attributes are both missing or have values that represent the same language, and whose [label<sup>p325</sup>](#) attributes are again both missing or both have the same value.

If the element has a [label<sup>p325</sup>](#) attribute whose value is not the empty string, then the element's `track label` is the value of the attribute. Otherwise, the element's [track label<sup>p325</sup>](#) is an empty string.

The `default` attribute is a [boolean attribute<sup>p59</sup>](#), which, if specified, indicates that the track is to be enabled if the user's preferences do not indicate that another track would be more appropriate.

Each [media element<sup>p326</sup>](#) must have no more than one [track<sup>p324</sup>](#) element child whose [kind<sup>p325</sup>](#) attribute is in the [subtitles<sup>p325</sup>](#) or [captions<sup>p325</sup>](#) state and whose [default<sup>p325</sup>](#) attribute is specified.

Each [media element<sup>p326</sup>](#) must have no more than one [track<sup>p324</sup>](#) element child whose [kind<sup>p325</sup>](#) attribute is in the [description<sup>p325</sup>](#) state and whose [default<sup>p325</sup>](#) attribute is specified.

Each [media element<sup>p326</sup>](#) must have no more than one [track<sup>p324</sup>](#) element child whose [kind<sup>p325</sup>](#) attribute is in the [chapters<sup>p325</sup>](#) state and whose [default<sup>p325</sup>](#) attribute is specified.

**Note** *There is no limit on the number of [track<sup>p324</sup>](#) elements whose [kind<sup>p325</sup>](#) attribute is in the [metadata<sup>p325</sup>](#) state and whose [default<sup>p325</sup>](#) attribute is specified.*

**Note**

**track.readyState<sup>p326</sup>**

Returns the [text track readiness state<sup>p366</sup>](#), represented by a number from the following list:

**track.NONE<sup>p326</sup> (0)**

The [text track not loaded<sup>p366</sup>](#) state.

**track.LOADING<sup>p326</sup> (1)**

The [text track loading<sup>p366</sup>](#) state.

**track.LOADED<sup>p326</sup> (2)**

The [text track loaded<sup>p366</sup>](#) state.

**track.ERROR<sup>p326</sup> (3)**

The [text track failed to load<sup>p366</sup>](#) state.

**track.track<sup>p326</sup>**

Returns the [TextTrack<sup>b374</sup>](#) object corresponding to the [text track<sup>p365</sup>](#) of the [track<sup>p324</sup>](#) element.

The **readyState** attribute must return the numeric value corresponding to the [text track readiness state<sup>p366</sup>](#) of the [track<sup>p324</sup>](#) element's [text track<sup>p365</sup>](#), as defined by the following list:

**NONE (numeric value 0)**

The [text track not loaded<sup>p366</sup>](#) state.

**LOADING (numeric value 1)**

The [text track loading<sup>p366</sup>](#) state.

**LOADED (numeric value 2)**

The [text track loaded<sup>p366</sup>](#) state.

**ERROR (numeric value 3)**

The [text track failed to load<sup>p366</sup>](#) state.

The **track** IDL attribute must, on getting, return the [track<sup>p324</sup>](#) element's [text track<sup>p365</sup>](#)'s corresponding [TextTrack<sup>b374</sup>](#) object.

The **src**, **srclang**, **label**, and **default** IDL attributes must [reflect<sup>p88</sup>](#) the respective content attributes of the same name. The **kind** IDL attribute must [reflect<sup>p88</sup>](#) the content attribute of the same name, [limited to only known values<sup>p89</sup>](#).

**Example**

This video has subtitles in several languages:

```
<video src="brave.webm">
 <track kind=subtitles src=brave.en.vtt srclang=en label="English">
 <track kind=captions src=brave.en.hoh.vtt srclang=en label="English for the Hard of Hearing">
 <track kind=subtitles src=brave.fr.vtt srclang=fr lang=fr label="Français">
 <track kind=subtitles src=brave.de.vtt srclang=de lang=de label="Deutsch">
</video>
```

(The [lang<sup>p123</sup>](#) attributes on the last two describe the language of the [label<sup>p325</sup>](#) attribute, not the language of the subtitles themselves. The language of the subtitles is given by the [srclang<sup>p325</sup>](#) attribute.)

#### 4.8.14 Media elements

Media elements ([audio<sup>p321</sup>](#) and [video<sup>p317</sup>](#), in this specification) implement the following interface:

```

enum CanPlayTypeResult { "" /* empty string */, "maybe", "probably" };
typedef (MediaStream or MediaSource or Blob) MediaProvider;
interface HTMLMediaElement : HTMLElement {

 // error state
 readonly attribute MediaError? error;

 // network state
 attribute DOMString src;
 attribute MediaProvider? srcObject;
 readonly attribute DOMString currentSrc;
 attribute DOMString? crossOrigin;
 const unsigned short NETWORK_EMPTY = 0;
 const unsigned short NETWORK_IDLE = 1;
 const unsigned short NETWORK_LOADING = 2;
 const unsigned short NETWORK_NO_SOURCE = 3;
 readonly attribute unsigned short networkState;
 attribute DOMString preload;
 readonly attribute TimeRanges buffered;
 void load();
 CanPlayTypeResult canPlayType(DOMString type);

 // ready state
 const unsigned short HAVE NOTHING = 0;
 const unsigned short HAVE_METADATA = 1;
 const unsigned short HAVE_CURRENT_DATA = 2;
 const unsigned short HAVE_FUTURE_DATA = 3;
 const unsigned short HAVE_ENOUGH_DATA = 4;
 readonly attribute unsigned short readyState;
 readonly attribute boolean seeking;

 // playback state
 attribute double currentTime;
 void fastSeek(double time);
 readonly attribute unrestricted double duration;
 Date getStartDate();
 readonly attribute boolean paused;
 attribute double defaultPlaybackRate;
 attribute double playbackRate;
 readonly attribute TimeRanges played;
 readonly attribute TimeRanges seekable;
 readonly attribute boolean ended;
 attribute boolean autoplay;
 attribute boolean loop;
 void play();
 void pause();

 // media controller
 attribute DOMString mediaGroup;
 attribute MediaController? controller;

 // controls
 attribute boolean controls;
 attribute double volume;
 attribute boolean muted;
 attribute boolean defaultMuted;

 // tracks
 [SameObject] readonly attribute AudioTrackList audioTracks;
}

```

```
[SameObject] readonly attribute VideoTrackList videoTracks;
[SameObject] readonly attribute TextTrackList textTracks;
TextTrack addTextTrack(TextTrackKind kind, optional DOMString label = "", optional DOMString language = "") ;
};
```

The [media element attributes](#), [src](#)<sup>p329</sup>, [crossorigin](#)<sup>p329</sup>, [preload](#)<sup>p340</sup>, [autoplay](#)<sup>p345</sup>, [mediagroup](#)<sup>p364</sup>, [loop](#)<sup>p343</sup>, [muted](#)<sup>p384</sup>, and [controls](#)<sup>p382</sup>, apply to all [media elements](#)<sup>p326</sup>. They are defined in this section.

[Media elements](#)<sup>p326</sup> are used to present audio data, or video and audio data, to the user. This is referred to as **media data** in this section, since this section applies equally to [media elements](#)<sup>p326</sup> for audio or for video. The term **media resource** is used to refer to the complete set of media data, e.g. the complete video file, or complete audio file.

A [media resource](#)<sup>p328</sup> can have multiple audio and video tracks. For the purposes of a [media element](#)<sup>p326</sup>, the video data of the [media resource](#)<sup>p328</sup> is only that of the currently selected track (if any) as given by the element's [videoTracks](#)<sup>p353</sup> attribute when the [event loop](#)<sup>p834</sup> last reached [step 1](#)<sup>p836</sup>, and the audio data of the [media resource](#)<sup>p328</sup> is the result of mixing all the currently enabled tracks (if any) given by the element's [audioTracks](#)<sup>p353</sup> attribute when the [event loop](#)<sup>p834</sup> last reached [step 1](#)<sup>p836</sup>.

**Note** Both [audio](#)<sup>p321</sup> and [video](#)<sup>p317</sup> elements can be used for both audio and video. The main difference between the two is simply that the [audio](#)<sup>p321</sup> element has no playback area for visual content (such as video or captions), whereas the [video](#)<sup>p317</sup> element does.

Except where otherwise explicitly specified, the [task source](#)<sup>p835</sup> for all the tasks [queued](#)<sup>p835</sup> in this section and its subsections is the **media element event task source** of the [media element](#)<sup>p326</sup> in question.

#### 4.8.14.1 Error codes

**Note**

[media . error](#)<sup>p328</sup>

Returns a [MediaError](#)<sup>p328</sup> object representing the current error state of the element.

Returns null if there is no error.

All [media elements](#)<sup>p326</sup> have an associated error status, which records the last error the element encountered since its [resource selection algorithm](#)<sup>p332</sup> was last invoked. The [error](#) attribute, on getting, must return the [MediaError](#)<sup>b328</sup> object created for this last error, or null if there has not been an error.

**IDL**

```
interface MediaError {
 const unsigned short MEDIA_ERR_ABORTED = 1;
 const unsigned short MEDIA_ERR_NETWORK = 2;
 const unsigned short MEDIA_ERR_DECODE = 3;
 const unsigned short MEDIA_ERR_SRC_NOT_SUPPORTED = 4;
 readonly attribute unsigned short code;
};
```

**Note**

[media . error](#)<sup>p328</sup> . [code](#)<sup>p328</sup>

Returns the current error's error code, from the list below.

The [code](#) attribute of a [MediaError](#)<sup>p328</sup> object must return the code for the error, which must be one of the following:

**MEDIA\_ERR\_ABORTED** (numeric value 1)

The fetching process for the [media resource](#)<sup>p328</sup> was aborted by the user agent at the user's request.

#### **MEDIA\_ERR\_NETWORK** (numeric value 2)

A network error of some description caused the user agent to stop fetching the [media resource](#)<sup>p328</sup>, after the resource was established to be usable.

#### **MEDIA\_ERR\_DECODE** (numeric value 3)

An error of some description occurred while decoding the [media resource](#)<sup>p328</sup>, after the resource was established to be usable.

#### **MEDIA\_ERR\_SRC\_NOT\_SUPPORTED** (numeric value 4)

The [media resource](#)<sup>p328</sup> indicated by the [src](#)<sup>p329</sup> attribute or [assigned media provider object](#)<sup>p329</sup> was not suitable.

### 4.8.14.2 Location of the media resource

The [src](#) content attribute on [media elements](#)<sup>p326</sup> gives the address of the media resource (video, audio) to show. The attribute, if present, must contain a [valid non-empty URL potentially surrounded by spaces](#)<sup>p82</sup>.

If the [itemprop](#)<sup>p692</sup> attribute is specified on the [media element](#)<sup>p326</sup>, then the [src](#)<sup>p329</sup> attribute must also be specified.

The [crossorigin](#) content attribute on [media elements](#)<sup>p326</sup> is a [CORS settings attribute](#)<sup>p87</sup>.

If a [media element](#)<sup>p326</sup> is created with a [src](#)<sup>p329</sup> attribute, the user agent must [immediately](#)<sup>p41</sup> invoke the [media element](#)<sup>p326</sup>'s [resource selection algorithm](#)<sup>p332</sup>.

If a [src](#)<sup>p329</sup> attribute of a [media element](#)<sup>p326</sup> is set or changed, the user agent must invoke the [media element](#)<sup>p326</sup>'s [media element load algorithm](#)<sup>p331</sup>. (Removing the [src](#)<sup>p329</sup> attribute does not do this, even if there are [source](#)<sup>p322</sup> elements present.)

The [src](#) IDL attribute on [media elements](#)<sup>p326</sup> must [reflect](#)<sup>p88</sup> the content attribute of the same name.

The [crossOrigin](#) IDL attribute must [reflect](#)<sup>p88</sup> the [crossorigin](#)<sup>p329</sup> content attribute.

A [media provider object](#) is an object that can represent a [media resource](#)<sup>p328</sup>, separate from a [URL](#)<sup>p48</sup>, [MediaStream](#)<sup>p52</sup> objects, [MediaSource](#)<sup>p52</sup> objects, [Blob](#)<sup>p52</sup> objects, and [File](#)<sup>p52</sup> objects are all [media provider objects](#)<sup>p329</sup>.

Each [media element](#)<sup>p326</sup> can have an [assigned media provider object](#), which is a [media provider object](#)<sup>p329</sup>. When a [media element](#)<sup>p326</sup> is created, it has no [assigned media provider object](#)<sup>p329</sup>.

#### Note

**media . srcObject**<sup>p329</sup> [= [source](#)]

Allows the [media element](#)<sup>p326</sup> to be assigned a [media provider object](#)<sup>p329</sup>.

**media . currentSrc**<sup>p329</sup>

Returns the address of the current [media resource](#)<sup>p328</sup>, if any.

Returns the empty string when there is no [media resource](#)<sup>p328</sup>, or it doesn't have an address.

The [currentSrc](#) IDL attribute must initially be set to the empty string. Its value is changed by the [resource selection algorithm](#)<sup>p332</sup> defined below.

The [srcObject](#) IDL attribute, on getting, must return the element's [assigned media provider object](#)<sup>p329</sup>, if any, or null otherwise. On setting, it must set the element's [assigned media provider object](#)<sup>p329</sup> to the new value, and then invoke the element's [media element load algorithm](#)<sup>p331</sup>.

**Note** There are three ways to specify a [media resource](#)<sup>p328</sup>: the [srcObject](#)<sup>p329</sup> IDL attribute, the [src](#)<sup>p329</sup> content attribute, and [source](#)<sup>p322</sup> elements. The IDL attribute takes priority, followed by the content attribute, followed by the elements.

### 4.8.14.3 MIME types

A [media resource](#)<sup>p328</sup> can be described in terms of its [type](#), specifically a [MIME type](#)<sup>p42</sup>, in some cases with a [codecs](#) parameter. (Whether the [codecs](#) parameter is allowed or not depends on the MIME type.) [\[RFC6381\]](#)<sup>p1153</sup>

Types are usually somewhat incomplete descriptions; for example "video/mpeg" doesn't say anything except what the container type is, and even a type like "video/mp4; codecs="avc1.42E01E, mp4a.40.2"" doesn't include information like the actual bitrate (only the maximum bitrate). Thus, given a type, a user agent can often only know whether it *might* be able to play media of that type (with varying levels of confidence), or whether it definitely *cannot* play media of that type.

**A type that the user agent knows it cannot render** is one that describes a resource that the user agent definitely does not support, for example because it doesn't recognise the container type, or it doesn't support the listed codecs.

The [MIME type<sup>p42</sup>](#) "application/octet-stream" with no parameters is never [a type that the user agent knows it cannot render<sup>p330</sup>](#). User agents must treat that type as equivalent to the lack of any explicit [Content-Type metadata<sup>p86</sup>](#) when it is used to label a potential [media resource<sup>p328</sup>](#).

**Note** Only the [MIME type<sup>p42</sup>](#) "application/octet-stream" with no parameters is special-cased here; if any parameter appears with it, it will be treated just like any other [MIME type<sup>p42</sup>](#). This is a deviation from the rule that unknown [MIME type<sup>p42</sup>](#) parameters should be ignored.

**Note**

`media . canPlayTypep330(type)`

Returns the empty string (a negative response), "maybe", or "probably" based on how confident the user agent is that it can play media resources of the given type.

The `canPlayType(type)` method must return the empty string if type is [a type that the user agent knows it cannot render<sup>p330</sup>](#) or is the type "application/octet-stream"; it must return "probably" if the user agent is confident that the type represents a [media resource<sup>p328</sup>](#) that it can render if used in with this [audio<sup>p321</sup>](#) or [video<sup>p317</sup>](#) element; and it must return "maybe" otherwise. Implementors are encouraged to return "maybe<sup>p330</sup>" unless the type can be confidently established as being supported or not. Generally, a user agent should never return "probably<sup>p330</sup>" for a type that allows the `codecs` parameter if that parameter is not present.

**Example**

This script tests to see if the user agent supports a (fictional) new format to dynamically decide whether to use a [video<sup>p317</sup>](#) element or a plugin:

```
<section id="video">
<p>Download video</p>
</section>
<script>
var videoSection = document.getElementById('video');
var videoElement = document.createElement('video');
var support = videoElement.canPlayType('video/x-new-fictional-format;codecs="kittens,bunnies"');
if (support != "probably" && "New Fictional Video Plugin" in navigator.plugins) {
 // not confident of browser support
 // but we have a plugin
 // so use plugin instead
 videoElement = document.createElement("embed");
} else if (support == "") {
 // no support from browser and no plugin
 // do nothing
 videoElement = null;
}
if (videoElement) {
 while (videoSection.hasChildNodes())
 videoSection.removeChild(videoSection.firstChild);
 videoElement.setAttribute("src", "playing-cats.nfv");
 videoSection.appendChild(videoElement);
}
</script>
```

**Note** The `typep322` attribute of the `sourcep322` element allows the user agent to avoid downloading resources that use formats it cannot render.

#### 4.8.14.4 Network states

##### Note

`media . networkStatep331`

Returns the current state of network activity for the element, from the codes in the list below.

As [media elements<sup>p326</sup>](#) interact with the network, their current network activity is represented by the [networkState](#) attribute. On getting, it must return the current network state of the element, which must be one of the following values:

##### [NETWORK\\_EMPTY](#) (numeric value 0)

The element has not yet been initialised. All attributes are in their initial states.

##### [NETWORK\\_IDLE](#) (numeric value 1)

The element's [resource selection algorithm<sup>p332</sup>](#) is active and has selected a [resource<sup>p328</sup>](#), but it is not actually using the network at this time.

##### [NETWORK\\_LOADING](#) (numeric value 2)

The user agent is actively trying to download data.

##### [NETWORK\\_NO\\_SOURCE](#) (numeric value 3)

The element's [resource selection algorithm<sup>p332</sup>](#) is active, but it has not yet found a [resource<sup>p328</sup>](#) to use.

The [resource selection algorithm<sup>p332</sup>](#) defined below describes exactly when the [networkState<sup>p331</sup>](#) attribute changes value and what events fire to indicate changes in this state.

#### 4.8.14.5 Loading the media resource

Spec bugs: [10711](#), [27989](#), [22471](#)

##### Note

`media . loadp331()`

Causes the element to reset and start selecting and loading a new [media resource<sup>p328</sup>](#) from scratch.

All [media elements<sup>p326</sup>](#) have an [autoplaying flag](#), which must begin in the true state, and a [delaying-the-load-event flag](#), which must begin in the false state. While the [delaying-the-load-event flag<sup>p331</sup>](#) is true, the element must [delay the load event<sup>b1033</sup>](#) of its document.

When the [load\(\)](#) method on a [media element<sup>p326</sup>](#) is invoked, the user agent must run the [media element load algorithm<sup>p331</sup>](#).

The [media element load algorithm](#) consists of the following steps.

1. Abort any already-running instance of the [resource selection algorithm<sup>p332</sup>](#) for this element.
2. If there are any [tasks<sup>p834</sup>](#) from the [media element<sup>p326</sup>](#)'s [media element event task source<sup>p328</sup>](#) in one of the [task queues<sup>p834</sup>](#), then remove those tasks.

**Note** Basically, pending events and callbacks for the media element are discarded when the media element starts loading a new resource.
3. If the [media element<sup>p326</sup>](#)'s [networkState<sup>p331</sup>](#) is set to [NETWORK\\_LOADING<sup>p331</sup>](#) or [NETWORK\\_IDLE<sup>p331</sup>](#), queue a task<sup>p835</sup> to [fire a simple event<sup>p846</sup>](#) named [abort<sup>p386</sup>](#) at the [media element<sup>p326</sup>](#).
4. If the [media element<sup>p326</sup>](#)'s [networkState<sup>p331</sup>](#) is not set to [NETWORK\\_EMPTY<sup>p331</sup>](#), then run these substeps:
  1. Queue a task<sup>p835</sup> to [fire a simple event<sup>p846</sup>](#) named [emptied<sup>p386</sup>](#) at the [media element<sup>p326</sup>](#).
  2. If a fetching process is in progress for the [media element<sup>p326</sup>](#), the user agent should stop it.
  3. [Forget the media element's media-resource-specific tracks<sup>b339</sup>](#).
  4. If [readyState<sup>b345</sup>](#) is not set to [HAVE NOTHING<sup>b343</sup>](#), then set it to that state.

5. If the [paused](#)<sup>p346</sup> attribute is false, then set it to true.

6. If [seeking](#)<sup>p351</sup> is true, set it to false.

7. Set the [current playback position](#)<sup>p342</sup> to 0.

Set the [official playback position](#)<sup>p342</sup> to 0.

If this changed the [official playback position](#)<sup>p342</sup>, then [queue a task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> named [timeupdate](#)<sup>p387</sup> at the [media element](#)<sup>p326</sup>.

8. Set the [timeline offset](#)<sup>p343</sup> to Not-a-Number (NaN).

9. Update the [duration](#)<sup>p342</sup> attribute to Not-a-Number (NaN).

**Note** *The user agent will not<sup>p342</sup> fire a [durationchange](#)<sup>p387</sup> event for this particular change of the duration.*

5. Set the [playbackRate](#)<sup>p347</sup> attribute to the value of the [defaultPlaybackRate](#)<sup>p347</sup> attribute.

6. Set the [error](#)<sup>p328</sup> attribute to null and the [autoplaying flag](#)<sup>p331</sup> to true.

7. Invoke the [media element](#)<sup>p326</sup>'s [resource selection algorithm](#)<sup>p332</sup>.

**Note** *Playback of any previously playing [media resource](#)<sup>p328</sup> for this element stops.*

The [resource selection algorithm](#) for a [media element](#)<sup>p326</sup> is as follows. This algorithm is always invoked as part of a [task](#)<sup>p834</sup>, but one of the first steps in the algorithm is to return and continue running the remaining steps [in parallel](#)<sup>p41</sup>. In addition, this algorithm interacts closely with the [event loop](#)<sup>p834</sup> mechanism; in particular, it has [synchronous sections](#)<sup>p837</sup> (which are triggered as part of the [event loop](#)<sup>p834</sup> algorithm). Steps in such sections are marked with  $\mathbb{X}$ .

1. Set the element's [networkState](#)<sup>p331</sup> attribute to the [NETWORK\\_NO\\_SOURCE](#)<sup>p331</sup> value.

2. Set the element's [show poster flag](#)<sup>p342</sup> to true.

3. Set the [media element](#)<sup>p326</sup>'s [delaying-the-load-event flag](#)<sup>p331</sup> to true (this [delays the load event](#)<sup>p1033</sup>).

4. [Await a stable state](#)<sup>p837</sup>, allowing the [task](#)<sup>p834</sup> that invoked this algorithm to continue. The [synchronous section](#)<sup>p837</sup> consists of all the remaining steps of this algorithm until the algorithm says the [synchronous section](#)<sup>p837</sup> has ended. (Steps in [synchronous sections](#)<sup>p837</sup> are marked with  $\mathbb{X}$ .)

5.  $\mathbb{X}$  If the [media element](#)<sup>p326</sup>'s [blocked-on-parser](#)<sup>p367</sup> flag is false, then [populate the list of pending text tracks](#)<sup>p367</sup>.

6.  $\mathbb{X}$  If the [media element](#)<sup>p326</sup> has an [assigned media provider object](#)<sup>p329</sup>, then let *mode* be *object*.

$\mathbb{X}$  Otherwise, if the [media element](#)<sup>p326</sup> has no [assigned media provider object](#)<sup>p329</sup> but has a [src](#)<sup>p329</sup> attribute, then let *mode* be *attribute*.

$\mathbb{X}$  Otherwise, if the [media element](#)<sup>p326</sup> does not have an [assigned media provider object](#)<sup>p329</sup> and does not have a [src](#)<sup>p329</sup> attribute, but does have a [source](#)<sup>p322</sup> element child, then let *mode* be *children* and let *candidate* be the first such [source](#)<sup>p322</sup> element child in [tree order](#)<sup>p42</sup>.

$\mathbb{X}$  Otherwise the [media element](#)<sup>p326</sup> has no [assigned media provider object](#)<sup>p329</sup> and has neither a [src](#)<sup>p329</sup> attribute nor a [source](#)<sup>p322</sup> element child: set the [networkState](#)<sup>p331</sup> to [NETWORK\\_EMPTY](#)<sup>p331</sup>, and abort these steps; the [synchronous section](#)<sup>p837</sup> ends.

7.  $\mathbb{X}$  Set the [media element](#)<sup>p326</sup>'s [networkState](#)<sup>p331</sup> to [NETWORK\\_LOADING](#)<sup>p331</sup>.

8.  $\mathbb{X}$  [Queue a task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> named [loadstart](#)<sup>p386</sup> at the [media element](#)<sup>p326</sup>.

9. Run the appropriate steps from the following list:

↪ If *mode* is *object*

1.  $\mathbb{X}$  Set the [currentSrc](#)<sup>p329</sup> attribute to the empty string.

2. End the [synchronous section](#)<sup>p837</sup>, continuing the remaining steps [in parallel](#)<sup>p41</sup>.

3. Run the [resource fetch algorithm](#)<sup>p334</sup> with the [assigned media provider object](#)<sup>p329</sup>. If that algorithm returns without aborting *this* one, then the load failed.

4. *Failed with media provider*: Reaching this step indicates that the media resource failed to load. [Queue a task](#)<sup>p835</sup> to run the [dedicated media source failure steps](#)<sup>p334</sup>.
5. Wait for the [task](#)<sup>p834</sup> queued by the previous step to have executed.
6. Abort these steps. The element won't attempt to load another resource until this algorithm is triggered again.

↪ **If mode is attribute**

1. ✎ If the [src](#)<sup>p329</sup> attribute's value is the empty string, then end the [synchronous section](#)<sup>p837</sup>, and jump down to the *failed with attribute* step below.
2. ✎ Let *absolute URL* be the [absolute URL](#)<sup>p48</sup> that would have resulted from [resolving](#)<sup>p82</sup> the [URL](#)<sup>p48</sup> specified by the [src](#)<sup>p329</sup> attribute's value relative to the [media element](#)<sup>p326</sup> when the [src](#)<sup>p329</sup> attribute was last changed.
3. ✎ If *absolute URL* was obtained successfully, set the [currentSrc](#)<sup>p329</sup> attribute to *absolute URL*.
4. End the [synchronous section](#)<sup>p837</sup>, continuing the remaining steps [in parallel](#)<sup>p41</sup>.
5. If *absolute URL* was obtained successfully, run the [resource fetch algorithm](#)<sup>p334</sup> with *absolute URL*. If that algorithm returns without aborting *this* one, then the load failed.
6. *Failed with attribute*: Reaching this step indicates that the media resource failed to load or that the given [URL](#)<sup>p48</sup> could not be [resolved](#)<sup>p82</sup>. [Queue a task](#)<sup>p835</sup> to run the [dedicated media source failure steps](#)<sup>p334</sup>.
7. Wait for the [task](#)<sup>p834</sup> queued by the previous step to have executed.
8. Abort these steps. The element won't attempt to load another resource until this algorithm is triggered again.

↪ **Otherwise (mode is children)**

1. ✎ Let *pointer* be a position defined by two adjacent nodes in the [media element](#)<sup>p326</sup>'s child list, treating the start of the list (before the first child in the list, if any) and end of the list (after the last child in the list, if any) as nodes in their own right. One node is the node before *pointer*, and the other node is the node after *pointer*. Initially, let *pointer* be the position between the *candidate* node and the next node, if there are any, or the end of the list, if it is the last node.

As [nodes are inserted](#)<sup>p43</sup> and [removed](#)<sup>p43</sup> into the [media element](#)<sup>p326</sup>, *pointer* must be updated as follows:

**If a new node is inserted**<sup>p43</sup> between the two nodes that define *pointer*

Let *pointer* be the point between the node before *pointer* and the new node. In other words, insertions at *pointer* go after *pointer*.

**If the node before *pointer* is removed**

Let *pointer* be the point between the node after *pointer* and the node before the node after *pointer*. In other words, *pointer* doesn't move relative to the remaining nodes.

**If the node after *pointer* is removed**

Let *pointer* be the point between the node before *pointer* and the node after the node before *pointer*. Just as with the previous case, *pointer* doesn't move relative to the remaining nodes.

Other changes don't affect *pointer*.

2. ✎ *Process candidate*: If *candidate* does not have a [src](#)<sup>p322</sup> attribute, or if its [src](#)<sup>p322</sup> attribute's value is the empty string, then end the [synchronous section](#)<sup>p837</sup>, and jump down to the *failed with elements* step below.
3. ✎ Let *absolute URL* be the [absolute URL](#)<sup>p48</sup> that would have resulted from [resolving](#)<sup>p82</sup> the [URL](#)<sup>p48</sup> specified by *candidate*'s [src](#)<sup>p322</sup> attribute's value relative to the *candidate* when the [src](#)<sup>p322</sup> attribute was last changed.
4. ✎ If *absolute URL* was not obtained successfully, then end the [synchronous section](#)<sup>p837</sup>, and jump down to the *failed with elements* step below.
5. ✎ If *candidate* has a [type](#)<sup>p322</sup> attribute whose value, when parsed as a [MIME type](#)<sup>p42</sup> (including any codecs described by the [codecs](#) parameter, for types that define that parameter), represents [a type that the user agent knows it cannot render](#)<sup>p330</sup>, then end the [synchronous section](#)<sup>p837</sup>, and jump down to the *failed with elements* step below.
6. ✎ Set the [currentSrc](#)<sup>p329</sup> attribute to *absolute URL*.

7. End the [synchronous section](#)<sup>p837</sup>, continuing the remaining steps [in parallel](#)<sup>p41</sup>.
8. Run the [resource fetch algorithm](#)<sup>p334</sup> with *absolute URL*. If that algorithm returns without aborting *this* one, then the load failed.
9. *Failed with elements:* [Queue a task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> named [error](#)<sup>p1144</sup> at the *candidate* element.
10. [Await a stable state](#)<sup>p837</sup>. The [synchronous section](#)<sup>p837</sup> consists of all the remaining steps of this algorithm until the algorithm says the [synchronous section](#)<sup>p837</sup> has ended. (Steps in [synchronous sections](#)<sup>p837</sup> are marked with  $\mathbb{X}$ .)
11.  $\mathbb{X}$  [Forget the media element's media-resource-specific tracks](#)<sup>p339</sup>.
12.  $\mathbb{X}$  *Find next candidate:* Let *candidate* be null.
13.  $\mathbb{X}$  *Search loop:* If the node after *pointer* is the end of the list, then jump to the *waiting* step below.
14.  $\mathbb{X}$  If the node after *pointer* is a [source](#)<sup>p322</sup> element, let *candidate* be that element.
15.  $\mathbb{X}$  Advance *pointer* so that the node before *pointer* is now the node that was after *pointer*, and the node after *pointer* is the node after the node that used to be after *pointer*, if any.
16.  $\mathbb{X}$  If *candidate* is null, jump back to the *search loop* step. Otherwise, jump back to the *process candidate* step.
17.  $\mathbb{X}$  *Waiting:* Set the element's [networkState](#)<sup>p331</sup> attribute to the [NETWORK\\_NO\\_SOURCE](#)<sup>p331</sup> value.
18.  $\mathbb{X}$  Set the element's [show poster flag](#)<sup>p342</sup> to true.
19.  $\mathbb{X}$  [Queue a task](#)<sup>p835</sup> to set the element's [delaying-the-load-event flag](#)<sup>p331</sup> to false. This stops [delaying the load event](#)<sup>p1033</sup>.
20. End the [synchronous section](#)<sup>p837</sup>, continuing the remaining steps [in parallel](#)<sup>p41</sup>.
21. Wait until the node after *pointer* is a node other than the end of the list. (This step might wait forever.)
22. [Await a stable state](#)<sup>p837</sup>. The [synchronous section](#)<sup>p837</sup> consists of all the remaining steps of this algorithm until the algorithm says the [synchronous section](#)<sup>p837</sup> has ended. (Steps in [synchronous sections](#)<sup>p837</sup> are marked with  $\mathbb{X}$ .)
23.  $\mathbb{X}$  Set the element's [delaying-the-load-event flag](#)<sup>p331</sup> back to true (this [delays the load event](#)<sup>p1033</sup> again, in case it hasn't been fired yet).
24.  $\mathbb{X}$  Set the [networkState](#)<sup>p331</sup> back to [NETWORK\\_LOADING](#)<sup>p331</sup>.
25.  $\mathbb{X}$  Jump back to the *find next candidate* step above.

The **dedicated media source failure steps** are the following steps:

1. Set the [error](#)<sup>p328</sup> attribute to a new [MediaError](#)<sup>p328</sup> object whose [code](#)<sup>p328</sup> attribute is set to [MEDIA\\_ERR\\_SRC\\_NOT\\_SUPPORTED](#)<sup>p329</sup>.
2. [Forget the media element's media-resource-specific tracks](#)<sup>p339</sup>.
3. Set the element's [networkState](#)<sup>p331</sup> attribute to the [NETWORK\\_NO\\_SOURCE](#)<sup>p331</sup> value.
4. Set the element's [show poster flag](#)<sup>p342</sup> to true.
5. [Fire a simple event](#)<sup>p846</sup> named [error](#)<sup>p386</sup> at the [media element](#)<sup>p326</sup>.
6. Set the element's [delaying-the-load-event flag](#)<sup>p331</sup> to false. This stops [delaying the load event](#)<sup>p1033</sup>.

The **resource fetch algorithm** for a [media element](#)<sup>p326</sup> and a given [absolute URL](#)<sup>p48</sup> or [media provider object](#)<sup>p329</sup> is as follows:

1. If the algorithm was invoked with a [URL](#)<sup>p48</sup>, then let *mode* be *remote*, otherwise let *mode* be *local*.
2. If *mode* is *local*, then let the *current media resource* be the resource given by the [absolute URL](#)<sup>p48</sup> passed to this algorithm; otherwise, let the *current media resource* be the resource given by the [media provider object](#)<sup>p329</sup>. Either way, the *current media resource* is now the element's [media resource](#)<sup>p328</sup>.
3. Remove all [media-resource-specific text tracks](#)<sup>p369</sup> from the [media element](#)<sup>p326</sup>'s [list of pending text tracks](#)<sup>p367</sup>, if any.

4. Run the appropriate steps from the following list:

↪ If **mode** is remote

1. Optionally, run the following substeps. This is the expected behaviour if the user agent intends to not attempt to fetch the resource until the user requests it explicitly (e.g. as a way to implement the preload<sup>b340</sup> attribute's none<sup>p340</sup> keyword).
  1. Set the networkState<sup>p331</sup> to NETWORK\_IDLE<sup>p331</sup>.
  2. Queue a task<sup>p835</sup> to fire a simple event<sup>p846</sup> named suspend<sup>p386</sup> at the element.
  3. Queue a task<sup>p835</sup> to set the element's delaying-the-load-event flag<sup>p331</sup> to false. This stops delaying the load event<sup>p1033</sup>.
  4. Wait for the task to be run.
  5. Wait for an implementation-defined event (e.g. the user requesting that the media element begin playback).
  6. Set the element's delaying-the-load-event flag<sup>p331</sup> back to true (this delays the load event<sup>b1033</sup> again, in case it hasn't been fired yet).
  7. Set the networkState<sup>p331</sup> to NETWORK\_LOADING<sup>p331</sup>.
2. Perform a potentially CORS-enabled fetch<sup>p87</sup> of the *current media resource's absolute URL*<sup>p48</sup>, with the **mode** being the state of the media element<sup>p326</sup>'s crossorigin<sup>p329</sup> content attribute, the **origin** being the origin<sup>b776</sup> of the media element<sup>p326</sup>'s node document, and the **default origin behaviour** set to *taint*.

The resource obtained in this fashion, if any, contains the media data<sup>p328</sup>. It can be CORS-same-origin<sup>p87</sup> or CORS-cross-origin<sup>p87</sup>; this affects whether subtitles referenced in the media data<sup>p328</sup> are exposed in the API and, for video<sup>p317</sup> elements, whether a canvas<sup>p607</sup> gets tainted when the video is drawn on it.

The **stall timeout** is a user-agent defined length of time, which should be about three seconds. When a media element<sup>p326</sup> that is actively attempting to obtain media data<sup>p328</sup> has failed to receive any data for a duration equal to the stall timeout<sup>p335</sup>, the user agent must queue a task<sup>p835</sup> to fire a simple event<sup>p846</sup> named stalled<sup>p386</sup> at the element.

User agents may allow users to selectively block or slow media data<sup>p328</sup> downloads. When a media element<sup>b326</sup>'s download has been blocked altogether, the user agent must act as if it was stalled (as opposed to acting as if the connection was closed). The rate of the download may also be throttled automatically by the user agent, e.g. to balance the download with other connections sharing the same bandwidth.

User agents may decide to not download more content at any time, e.g. after buffering five minutes of a one hour media resource, while waiting for the user to decide whether to play the resource or not, while waiting for user input in an interactive resource, or when the user navigates away from the page. When a media element<sup>p326</sup>'s download has been suspended, the user agent must queue a task<sup>p835</sup>, to set the networkState<sup>p331</sup> to NETWORK\_IDLE<sup>p331</sup> and fire a simple event<sup>p846</sup> named suspend<sup>p386</sup> at the element. If and when downloading of the resource resumes, the user agent must queue a task<sup>p835</sup> to set the networkState<sup>p331</sup> to NETWORK\_LOADING<sup>p331</sup>. Between the queuing of these tasks, the load is suspended (so progress<sup>p386</sup> events don't fire, as described above).

**Note** The preload<sup>p340</sup> attribute provides a hint regarding how much buffering the author thinks is advisable, even in the absence of the autoplay<sup>p345</sup> attribute.

When a user agent decides to completely stall a download, e.g. if it is waiting until the user starts playback before downloading any further content, the user agent must queue a task<sup>p835</sup> to set the element's delaying-the-load-event flag<sup>p331</sup> to false. This stops delaying the load event<sup>p1033</sup>.

The user agent may use whatever means necessary to fetch the resource (within the constraints put forward by this and other specifications); for example, reconnecting to the server in the face of network errors, using HTTP range retrieval requests, or switching to a streaming protocol. The user agent must consider a resource erroneous only if it has given up trying to fetch it.

To determine the format of the [media resource](#)<sup>p328</sup>, the user agent must use the [rules for sniffing audio and video specifically](#).

While the load is not suspended (see below), every 350ms ( $\pm 200\text{ms}$ ) or for every byte received, whichever is *least* frequent, [queue a task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> named [progress](#)<sup>p386</sup> at the element.

The [networking task source](#)<sup>p839</sup> [tasks](#)<sup>p834</sup> to process the data as it is being fetched must each [immediately](#)<sup>p41</sup> [queue a task](#)<sup>p835</sup> to run the first appropriate steps from the [media data processing steps list](#)<sup>p336</sup> below. (A new task is used for this so that the work described below occurs relative to the [media element event task source](#)<sup>p328</sup> rather than the [networking task source](#)<sup>p839</sup>.)

When the [networking task source](#)<sup>p839</sup> has [queued](#)<sup>p835</sup> the last [task](#)<sup>p834</sup> as part of [fetching](#)<sup>p84</sup> the [media resource](#)<sup>p328</sup> (i.e. once the download has completed), if the fetching process completes without errors, including decoding the media data, and if all of the data is available to the user agent without network access, then, the user agent must move on to the *final step* below. This might never happen, e.g. when streaming an infinite resource such as Web radio, or if the resource is longer than the user agent's ability to cache data.

While the user agent might still need network access to obtain parts of the [media resource](#)<sup>p328</sup>, the user agent must remain on this step.

**Example** For example, if the user agent has discarded the first half of a video, the user agent will remain at this step even once the [playback has ended](#)<sup>p346</sup>, because there is always the chance the user will seek back to the start. In fact, in this situation, once [playback has ended](#)<sup>p346</sup>, the user agent will end up firing a [suspend](#)<sup>p386</sup> event, as described earlier.

↪ **Otherwise (mode is local)**

The resource described by the [current media resource](#), if any, contains the [media data](#)<sup>p328</sup>. It is [CORS-same-origin](#)<sup>p87</sup>.

If the [current media resource](#) is a raw data stream (e.g. from a [File](#)<sup>p52</sup> object), then to determine the format of the [media resource](#)<sup>p328</sup>, the user agent must use the [rules for sniffing audio and video specifically](#). Otherwise, if the data stream is pre-decoded, then the format is given by the relevant specification.

Whenever new data for the [current media resource](#) becomes available, [queue a task](#)<sup>p835</sup> to run the first appropriate steps from the [media data processing steps list](#)<sup>p336</sup> below.

When the [current media resource](#) is permanently exhausted (e.g. all the bytes of a [Blob](#)<sup>p52</sup> have been processed), if there were no decoding errors, then the user agent must move on to the *final step* below. This might never happen, e.g. if the [current media resource](#) is a [MediaStream](#)<sup>p52</sup>.

The [media data processing steps list](#) is as follows:

- ↪ If the [media data](#)<sup>p328</sup> cannot be fetched at all, due to network errors, causing the user agent to give up trying to fetch the resource
- ↪ If the [media data](#)<sup>p328</sup> can be fetched but is found by inspection to be in an unsupported format, or can otherwise not be rendered at all

DNS errors, HTTP 4xx and 5xx errors (and equivalents in other protocols), and other fatal network errors that occur before the user agent has established whether the [current media resource](#) is usable, as well as the file using an unsupported container format, or using unsupported codecs for all the data, must cause the user agent to execute the following steps:

1. The user agent should cancel the fetching process.
2. Abort this subalgorithm, returning to the [resource selection algorithm](#)<sup>p332</sup>.

↪ If the [media resource](#)<sup>p328</sup> is found to have an audio track

1. Create an [AudioTrack](#)<sup>p354</sup> object to represent the audio track.
2. Update the [media element](#)<sup>p326</sup>'s [audioTracks](#)<sup>p353</sup> attribute's [AudioTrackList](#)<sup>p354</sup> object with the new [AudioTrack](#)<sup>p354</sup> object.
3. Let *enable* be *unknown*.
4. If either the [media resource](#)<sup>p328</sup> or the address of the [current media resource](#) indicate a particular set of audio tracks to enable, or if the user agent has information that would facilitate the selection of specific audio tracks to

improve the user's experience, then: if this audio track is one of the ones to enable, then set `enable` to `true`, otherwise, set `enable` to `false`.

**Example** This could be triggered by *Media Fragments URI* fragment identifier syntax, but it could also be triggered e.g. by the user agent selecting a 5.1 surround sound audio track over a stereo audio track.  
[MEDIAFRAG]<sup>p1151</sup>

5. If `enable` is still `unknown`, then, if the `media element`<sup>p326</sup> does not yet have an `enabled`<sup>p357</sup> audio track, then set `enable` to `true`, otherwise, set `enable` to `false`.
6. If `enable` is `true`, then enable this audio track, otherwise, do not enable this audio track.
7. Fire<sup>p43</sup> a trusted<sup>p43</sup> event with the name `addtrack`<sup>p387</sup>, that does not bubble and is not cancelable, and that uses the `TrackEvent`<sup>p385</sup> interface, with the `track`<sup>p385</sup> attribute initialised to the new `AudioTrack`<sup>p354</sup> object, at this `AudioTrackList`<sup>p354</sup> object.

↪ If the `media resource`<sup>p328</sup> is found to have a video track

1. Create a `VideoTrack`<sup>p354</sup> object to represent the video track.
2. Update the `media element`<sup>p326</sup>'s `videoTracks`<sup>p353</sup> attribute's `VideoTrackList`<sup>p354</sup> object with the new `VideoTrack`<sup>p354</sup> object.
3. Let `enable` be `unknown`.
4. If either the `media resource`<sup>p328</sup> or the address of the *current media resource* indicate a particular set of video tracks to enable, or if the user agent has information that would facilitate the selection of specific video tracks to improve the user's experience, then: if this video track is the first such video track, then set `enable` to `true`, otherwise, set `enable` to `false`.

**Example** This could again be triggered by *Media Fragments URI* fragment identifier syntax.

5. If `enable` is still `unknown`, then, if the `media element`<sup>p326</sup> does not yet have a `selected`<sup>p357</sup> video track, then set `enable` to `true`, otherwise, set `enable` to `false`.
6. If `enable` is `true`, then select this track and unselect any previously selected video tracks, otherwise, do not select this video track. If other tracks are unselected, then a change event will be fired.<sup>p357</sup>
7. Fire<sup>p43</sup> a trusted<sup>p43</sup> event with the name `addtrack`<sup>p387</sup>, that does not bubble and is not cancelable, and that uses the `TrackEvent`<sup>p385</sup> interface, with the `track`<sup>p385</sup> attribute initialised to the new `VideoTrack`<sup>p354</sup> object, at this `VideoTrackList`<sup>p354</sup> object.

↪ Once enough of the `media data`<sup>p328</sup> has been fetched to determine the duration of the `media resource`<sup>p328</sup>, its dimensions, and other metadata

This indicates that the resource is usable. The user agent must follow these substeps:

1. Establish the `media timeline`<sup>p341</sup> for the purposes of the `current playback position`<sup>p342</sup> and the `earliest possible position`<sup>p342</sup>, based on the `media data`<sup>p328</sup>.
2. Update the `timeline offset`<sup>p343</sup> to the date and time that corresponds to the zero time in the `media timeline`<sup>p341</sup> established in the previous step, if any. If no explicit time and date is given by the `media resource`<sup>p328</sup>, the `timeline offset`<sup>p343</sup> must be set to Not-a-Number (NaN).
3. Set the `current playback position`<sup>p342</sup> and the `official playback position`<sup>p342</sup> to the `earliest possible position`<sup>p342</sup>.
4. Update the `duration`<sup>p342</sup> attribute with the time of the last frame of the resource, if known, on the `media timeline`<sup>p341</sup> established above. If it is not known (e.g. a stream that is in principle infinite), update the `duration`<sup>p342</sup> attribute to the value positive Infinity.

**Note** The user agent will<sup>p342</sup> queue a task<sup>p835</sup> to fire a simple event<sup>p846</sup> named `durationchange`<sup>p387</sup> at the element at this point.

5. For `video`<sup>p317</sup> elements, set the `videoWidth`<sup>p319</sup> and `videoHeight`<sup>p319</sup> attributes, and queue a task<sup>p835</sup> to fire a simple event<sup>p846</sup> named `resize`<sup>p387</sup> at the `media element`<sup>p326</sup>.

**Note** Further `resize`<sup>p387</sup> events will be fired if the dimensions subsequently change.

6. Set the `readyState`<sup>p345</sup> attribute to `HAVE_METADATA`<sup>p343</sup>.

**Note** A `loadedmetadata`<sup>p386</sup> DOM event will be fired<sup>p344</sup> as part of setting the `readyState`<sup>p345</sup> attribute to a new value.

7. Let `jumped` be false.
8. If the `media_element`<sup>p326</sup>'s `default playback start position`<sup>p342</sup> is greater than zero, then `seek`<sup>p351</sup> to that time, and let `jumped` be true.
9. Let the `media_element`<sup>p326</sup>'s `default playback start position`<sup>p342</sup> be zero.
10. Let the *initial playback position* be zero.
11. If either the `media resource`<sup>p328</sup> or the address of the *current media resource* indicate a particular start time, then set the *initial playback position* to that time and, if `jumped` is still false, `seek`<sup>p351</sup> to that time and let `jumped` be true.

**Example** For example, with media formats that support the *Media Fragments URI* fragment identifier syntax, the fragment identifier can be used to indicate a start position. `[MEDIAFRAG]`<sup>p1151</sup>

12. If there is no `enabled`<sup>p357</sup> audio track, then enable an audio track. This will cause a `change` event to be fired<sup>p357</sup>.
13. If there is no `selected`<sup>p357</sup> video track, then select a video track. This will cause a `change` event to be fired<sup>p357</sup>.
14. If the `media_element`<sup>p326</sup> has a `current media controller`<sup>p360</sup>, then: if `jumped` is true and the *initial playback position*, relative to the `current media controller`<sup>p360</sup>'s timeline, is greater than the `current media controller`<sup>p360</sup>'s `media controller position`<sup>p362</sup>, then `seek the media controller`<sup>p362</sup> to the `media_element`<sup>p326</sup>'s *initial playback position*, relative to the `current media controller`<sup>p360</sup>'s timeline; otherwise, `seek`<sup>p351</sup> the `media_element`<sup>p326</sup> to the `media controller position`<sup>p362</sup>, relative to the `media_element`<sup>p326</sup>'s timeline.

Once the `readyState`<sup>p345</sup> attribute reaches `HAVE_CURRENT_DATA`<sup>p343</sup>, after the `loadeddata` event has been fired<sup>p344</sup>, set the element's `delaying-the-load-event flag`<sup>p331</sup> to false. This stops delaying the load event<sup>p1033</sup>.

**Note** A user agent that is attempting to reduce network usage while still fetching the metadata for each `media resource`<sup>p328</sup> would also stop buffering at this point, following the rules described previously<sup>p335</sup>, which involve the `networkState`<sup>p331</sup> attribute switching to the `NETWORK_IDLE`<sup>p331</sup> value and a `suspend`<sup>p386</sup> event firing.

**Note** The user agent is required to determine the duration of the `media resource`<sup>p328</sup> and go through this step before playing.

↪ Once the entire `media resource`<sup>p328</sup> has been `fetched`<sup>p84</sup> (but potentially before any of it has been decoded)

Fire a simple event<sup>p846</sup> named `progress`<sup>p386</sup> at the `media_element`<sup>p326</sup>.

Set the `networkState`<sup>p331</sup> to `NETWORK_IDLE`<sup>p331</sup> and fire a simple event<sup>p846</sup> named `suspend`<sup>p386</sup> at the `media_element`<sup>p326</sup>.

If the user agent ever discards any `media data`<sup>p328</sup> and then needs to resume the network activity to obtain it again, then it must `queue a task`<sup>p835</sup> to set the `networkState`<sup>p331</sup> to `NETWORK_LOADING`<sup>p331</sup>.

**Note** If the user agent can keep the `media resource`<sup>p328</sup> loaded, then the algorithm will continue to its final step below, which aborts the algorithm.

↪ If the connection is interrupted after some `media data`<sup>p328</sup> has been received, causing the user agent to give up trying to fetch the resource

Fatal network errors that occur after the user agent has established whether the *current media resource* is usable (i.e. once the `media_element`<sup>p326</sup>'s `readyState`<sup>p345</sup> attribute is no longer `HAVE NOTHING`<sup>p343</sup>) must cause the user agent to execute the following steps:

1. The user agent should cancel the fetching process.
2. Set the `error`<sup>p328</sup> attribute to a new `MediaError`<sup>p328</sup> object whose `code`<sup>p328</sup> attribute is set to `MEDIA_ERR_NETWORK`<sup>p329</sup>.
3. Set the element's `networkState`<sup>p331</sup> attribute to the `NETWORK_IDLE`<sup>p331</sup> value.
4. Set the element's `delaying-the-load-event flag`<sup>p331</sup> to false. This stops delaying the load event<sup>p1033</sup>.

5. [Fire a simple event](#)<sup>p846</sup> named `error`<sup>p386</sup> at the [media element](#)<sup>p326</sup>.

6. Abort the overall [resource selection algorithm](#)<sup>p332</sup>.

↪ If the [media data](#)<sup>p328</sup> is corrupted

Fatal errors in decoding the [media data](#)<sup>p328</sup> that occur after the user agent has established whether the *current media resource* is usable (i.e. once the [media element](#)<sup>p326</sup>'s `readyState`<sup>p345</sup> attribute is no longer `HAVE NOTHING`<sup>p343</sup>) must cause the user agent to execute the following steps:

1. The user agent should cancel the fetching process.
2. Set the `error`<sup>p328</sup> attribute to a new [MediaError](#)<sup>p328</sup> object whose `code`<sup>p328</sup> attribute is set to `MEDIA_ERR_DECODE`<sup>p329</sup>.
3. Set the element's `networkState`<sup>p331</sup> attribute to the `NETWORK_IDLE`<sup>p331</sup> value.
4. Set the element's [delaying-the-load-event flag](#)<sup>p331</sup> to false. This stops [delaying the load event](#)<sup>p1033</sup>.
5. [Fire a simple event](#)<sup>p846</sup> named `error`<sup>p386</sup> at the [media element](#)<sup>p326</sup>.
6. Abort the overall [resource selection algorithm](#)<sup>p332</sup>.

↪ If the [media data](#)<sup>p328</sup> fetching process is aborted by the user

The fetching process is aborted by the user, e.g. because the user pressed a "stop" button, the user agent must execute the following steps. These steps are not followed if the `load()`<sup>p331</sup> method itself is invoked while these steps are running, as the steps above handle that particular kind of abort.

1. The user agent should cancel the fetching process.
2. Set the `error`<sup>p328</sup> attribute to a new [MediaError](#)<sup>p328</sup> object whose `code`<sup>p328</sup> attribute is set to `MEDIA_ERR_ABORTED`<sup>p328</sup>.
3. [Fire a simple event](#)<sup>p846</sup> named `abort`<sup>p386</sup> at the [media element](#)<sup>p326</sup>.
4. If the [media element](#)<sup>p326</sup>'s `readyState`<sup>p345</sup> attribute has a value equal to `HAVE NOTHING`<sup>p343</sup>, set the element's `networkState`<sup>p331</sup> attribute to the `NETWORK_EMPTY`<sup>p331</sup> value, set the element's [show poster flag](#)<sup>p342</sup> to true, and [fire a simple event](#)<sup>p846</sup> named `emptied`<sup>p386</sup> at the element.  
Otherwise, set the element's `networkState`<sup>p331</sup> attribute to the `NETWORK_IDLE`<sup>p331</sup> value.
5. Set the element's [delaying-the-load-event flag](#)<sup>p331</sup> to false. This stops [delaying the load event](#)<sup>p1033</sup>.
6. Abort the overall [resource selection algorithm](#)<sup>p332</sup>.

↪ If the [media data](#)<sup>p328</sup> can be fetched but has non-fatal errors or uses, in part, codecs that are unsupported, preventing the user agent from rendering the content completely correctly but not preventing playback altogether

The server returning data that is partially usable but cannot be optimally rendered must cause the user agent to render just the bits it can handle, and ignore the rest.

↪ If the [media resource](#)<sup>p328</sup> is found to declare a [media-resource-specific text track](#)<sup>p369</sup> that the user agent supports

If the [media data](#)<sup>p328</sup> is [CORS-same-origin](#)<sup>p87</sup>, run the [steps to expose a media-resource-specific text track](#)<sup>p369</sup> with the relevant data.

**Note** Cross-origin videos do not expose their subtitles, since that would allow attacks such as hostile sites reading subtitles from confidential videos on a user's intranet. Spec bugs: [24910](#)

5. *Final step:* If the user agent ever reaches this step (which can only happen if the entire resource gets loaded and kept available): abort the overall [resource selection algorithm](#)<sup>p332</sup>.

When a [media element](#)<sup>p326</sup> is to forget the media element's media-resource-specific tracks, the user agent must remove from the [media element](#)<sup>p326</sup>'s [list of text tracks](#)<sup>p365</sup> all the [media-resource-specific text tracks](#)<sup>p369</sup>, then empty the [media element](#)<sup>p326</sup>'s [audioTracks](#)<sup>p353</sup> attribute's [AudioTrackList](#)<sup>p354</sup> object, then empty the [media element](#)<sup>p326</sup>'s [videoTracks](#)<sup>p353</sup> attribute's [VideoTrackList](#)<sup>p354</sup> object. No events (in particular, no [removetrack](#)<sup>p387</sup> events) are fired as part of this; the `error`<sup>p386</sup> and `emptied`<sup>p386</sup> events, fired by the algorithms that invoke this one, can be used instead.

The `preload` attribute is an [enumerated attribute<sup>p60</sup>](#). The following table lists the keywords and states for the attribute — the keywords in the left column map to the states in the cell in the second column on the same row as the keyword. The attribute can be changed even once the [media resource<sup>p328</sup>](#) is being buffered or played; the descriptions in the table below are to be interpreted with that in mind.

Keyword	State	Brief description
<code>none</code>	<code>None</code>	Hints to the user agent that either the author does not expect the user to need the media resource, or that the server wants to minimise unnecessary traffic. This state does not provide a hint regarding how aggressively to actually download the media resource if buffering starts anyway (e.g. once the user hits "play").
<code>metadata</code>	<code>Metadata</code>	Hints to the user agent that the author does not expect the user to need the media resource, but that fetching the resource metadata (dimensions, track list, duration, etc), and maybe even the first few frames, is reasonable. If the user agent precisely fetches no more than the metadata, then the <a href="#">media element<sup>p326</sup></a> will end up with its <a href="#">readyState<sup>p345</sup></a> attribute set to <a href="#">HAVE_METADATA<sup>p343</sup></a> ; typically though, some frames will be obtained as well and it will probably be <a href="#">HAVE_CURRENT_DATA<sup>p343</sup></a> or <a href="#">HAVE_FUTURE_DATA<sup>p343</sup></a> . When the media resource is playing, hints to the user agent that bandwidth is to be considered scarce, e.g. suggesting throttling the download so that the media data is obtained at the slowest possible rate that still maintains consistent playback.
<code>auto</code>	<code>Automatic</code>	Hints to the user agent that the user agent can put the user's needs first without risk to the server, up to and including optimistically downloading the entire resource.

The empty string is also a valid keyword, and maps to the [Automatic<sup>p340</sup>](#) state. The attribute's [missing value default<sup>p60</sup>](#) is user-agent defined, though the [Metadata<sup>p340</sup>](#) state is suggested as a compromise between reducing server load and providing an optimal user experience.

**Note** Authors might switch the attribute from "`nonep340`" or "`metadatap340`" to "`autop340`" dynamically once the user begins playback. For example, on a page with many videos this might be used to indicate that the many videos are not to be downloaded unless requested, but that once one is requested it is to be downloaded aggressively.

The `preload` attribute is intended to provide a hint to the user agent about what the author thinks will lead to the best user experience. The attribute may be ignored altogether, for example based on explicit user preferences or based on the available connectivity.

The `preload` IDL attribute must [reflect<sup>p88</sup>](#) the content attribute of the same name, [limited to only known values<sup>p89</sup>](#).

**Note** The [autoplay<sup>p345</sup>](#) attribute can override the `preload` attribute (since if the media plays, it naturally has to buffer first, regardless of the hint given by the `preloadp340` attribute). Including both is not an error, however.

**Note** `media . bufferedp340`  
Returns a [TimeRanges<sup>p384</sup>](#) object that represents the ranges of the [media resource<sup>p328</sup>](#) that the user agent has buffered.

The `buffered` attribute must return a new static [normalised TimeRanges object<sup>p385</sup>](#) that represents the ranges of the [media resource<sup>p328</sup>](#), if any, that the user agent has buffered, at the time the attribute is evaluated. User agents must accurately determine the ranges available, even for media streams where this can only be determined by tedious inspection.

**Note** Typically this will be a single range anchored at the zero point, but if, e.g. the user agent uses HTTP range requests in response to seeking, then there could be multiple ranges.

User agents may discard previously buffered data.

**Note** Thus, a time position included within a range of the objects return by the `bufferedp340` attribute at one time can end up being not included in the range(s) of objects returned by the same attribute at later times.

#### 4.8.14.6 Offsets into the media resource

**Note** `media . durationp342`  
Returns the length of the [media resource<sup>p328</sup>](#), in seconds, assuming that the start of the [media resource<sup>p328</sup>](#) is at time zero.  
Returns NaN if the duration isn't available.  
Returns Infinity for unbounded streams.

### `media.currentTimep342 [= value]`

Returns the [official playback position<sup>p342</sup>](#), in seconds.

Can be set, to seek to the given time.

Will throw an [InvalidStateError<sup>p50</sup>](#) exception if there is no selected [media resource<sup>p328</sup>](#) or if there is a [current media controller<sup>p360</sup>](#).

A [media resource<sup>p328</sup>](#) has a [media timeline](#) that maps times (in seconds) to positions in the [media resource<sup>p328</sup>](#). The origin of a timeline is its earliest defined position. The duration of a timeline is its last defined position.

**Establishing the media timeline:** If the [media resource<sup>p328</sup>](#) somehow specifies an explicit timeline whose origin is not negative (i.e. gives each frame a specific time offset and gives the first frame a zero or positive offset), then the [media timeline<sup>p341</sup>](#) should be that timeline. (Whether the [media resource<sup>p328</sup>](#) can specify a timeline or not depends on the [media resource's<sup>p328</sup>](#) format.) If the [media resource<sup>p328</sup>](#) specifies an explicit start time *and date*, then that time and date should be considered the zero point in the [media timeline<sup>p341</sup>](#); the [timeline offset<sup>p343</sup>](#) will be the time and date, exposed using the [getStartDate\(\)<sup>p343</sup>](#) method.

If the [media resource<sup>p328</sup>](#) has a discontinuous timeline, the user agent must extend the timeline used at the start of the resource across the entire resource, so that the [media timeline<sup>p341</sup>](#) of the [media resource<sup>p328</sup>](#) increases linearly starting from the [earliest possible position<sup>p342</sup>](#) (as defined below), even if the underlying [media data<sup>p328</sup>](#) has out-of-order or even overlapping time codes.

**Example** For example, if two clips have been concatenated into one video file, but the video format exposes the original times for the two clips, the video data might expose a timeline that goes, say, 00:15..00:29 and then 00:05..00:38. However, the user agent would not expose those times; it would instead expose the times as 00:15..00:29 and 00:29..01:02, as a single video.

In the rare case of a [media resource<sup>p328</sup>](#) that does not have an explicit timeline, the zero time on the [media timeline<sup>p341</sup>](#) should correspond to the first frame of the [media resource<sup>p328</sup>](#). In the even rarer case of a [media resource<sup>p328</sup>](#) with no explicit timings of any kind, not even frame durations, the user agent must itself determine the time for each frame in a user-agent-defined manner.

p30

**Note** An example of a file format with no explicit timeline but with explicit frame durations is the Animated GIF format. An example of a file with no explicit timings at all is the JPEG-push format ([multipart/x-mixed-replace<sup>p117</sup>](#) with JPEG frames, often used as the . for MJPEG streams).

If, in the case of a resource with no timing information, the user agent will nonetheless be able to seek to an earlier point than the first frame originally provided by the server, then the zero time should correspond to the earliest seekable time of the [media resource<sup>p328</sup>](#); otherwise, it should correspond to the first frame received from the server (the point in the [media resource<sup>p328</sup>](#) at which the user agent began receiving the stream).

**Note** At the time of writing, there is no known format that lacks explicit frame time offsets yet still supports seeking to a frame before the first frame sent by the server.

**Example**

Consider a stream from a TV broadcaster, which begins streaming on a sunny Friday afternoon in October, and always sends connecting user agents the media data on the same media timeline, with its zero time set to the start of this stream. Months later, user agents connecting to this stream will find that the first frame they receive has a time with millions of seconds. The [getStartDate\(\)<sup>p343</sup>](#) method would always return the date that the broadcast started; this would allow controllers to display real times in their scrubber (e.g. "2:30pm") rather than a time relative to when the broadcast began ("8 months, 4 hours, 12 minutes, and 23 seconds").

Consider a stream that carries a video with several concatenated fragments, broadcast by a server that does not allow user agents to request specific times but instead just streams the video data in a predetermined order, with the first frame delivered always being identified as the frame with time zero. If a user agent connects to this stream and receives fragments defined as covering timestamps 2010-03-20 23:15:00 UTC to 2010-03-21 00:05:00 UTC and 2010-02-12 14:25:00 UTC to 2010-02-12 14:35:00 UTC, it would expose this with a [media timeline<sup>p341</sup>](#) starting at 0s and extending to 3,600s (one hour). Assuming the streaming server disconnected at the end of the second clip, the [duration<sup>p342</sup>](#) attribute would then return 3,600. The [getStartDate\(\)<sup>p343</sup>](#) method would return a [Date<sup>p49</sup>](#) object with a time corresponding to 2010-03-20 23:15:00 UTC. However, if a different user agent connected five minutes later, it would (presumably) receive fragments covering timestamps 2010-03-20 23:20:00 UTC to 2010-03-21 00:05:00 UTC and 2010-02-12 14:25:00 UTC to 2010-02-12 14:35:00 UTC, and would expose this with a [media timeline<sup>p341</sup>](#) starting at 0s and extending to 3,300s (fifty five minutes). In this case, the [getStartDate\(\)<sup>p343</sup>](#) method would return a [Date<sup>p49</sup>](#) object with a time corresponding to 2010-03-20 23:20:00 UTC.

In both of these examples, the [seekable<sup>p352</sup>](#) attribute would give the ranges that the controller would want to actually display in its UI; typically, if the servers don't support seeking to arbitrary times, this would be the range of time from the moment the user agent

connected to the stream up to the latest frame that the user agent has obtained; however, if the user agent starts discarding earlier information, the actual range might be shorter.

In any case, the user agent must ensure that the [earliest possible position](#) (as defined below) using the established [media timeline](#), is greater than or equal to zero.

The [media timeline](#) also has an associated clock. Which clock is used is user-agent defined, and may be [media resource](#)-dependent, but it should approximate the user's wall clock.

**Note** All the [media elements](#) that share [current media controller](#) use the same clock for their [media timeline](#).

[Media elements](#) have a **current playback position**, which must initially (i.e. in the absence of [media data](#)) be zero seconds. The [current playback position](#) is a time on the [media timeline](#).

[Media elements](#) also have an **official playback position**, which must initially be set to zero seconds. The [official playback position](#) is an approximation of the [current playback position](#) that is kept stable while scripts are running.

[Media elements](#) also have a **default playback start position**, which must initially be set to zero seconds. This time is used to allow the element to be seeked even before the media is loaded.

Each [media element](#) has a **show poster flag**. When a [media element](#) is created, this flag must be set to true. This flag is used to control when the user agent is to show a poster frame for a [video](#) element instead of showing the video contents.

The [currentTime](#) attribute must, on getting, return the [media element](#)'s [default playback start position](#), unless that is zero, in which case it must return the element's [official playback position](#). The returned value must be expressed in seconds. On setting, if the [media element](#) has a [current media controller](#), then the user agent must throw an [InvalidStateError](#) exception; otherwise, if the [media element](#)'s [readyState](#) is [HAVE NOTHING](#), then it must set the [media element](#)'s [default playback start position](#) to the new value; otherwise, it must set the [official playback position](#) to the new value and then [seek](#) to the new value. The new value must be interpreted as being in seconds.

If the [media resource](#) is a streaming resource, then the user agent might be unable to obtain certain parts of the resource after it has expired from its buffer. Similarly, some [media resources](#) might have a [media timeline](#) that doesn't start at zero. The **earliest possible position** is the earliest position in the stream or resource that the user agent can ever obtain again. It is also a time on the [media timeline](#).

**Note** The [earliest possible position](#) is not explicitly exposed in the API; it corresponds to the start time of the first range in the [seekable](#) attribute's [TimeRanges](#) object, if any, or the [current playback position](#) otherwise.

When the [earliest possible position](#) changes, then: if the [current playback position](#) is before the [earliest possible position](#), the user agent must [seek](#) to the [earliest possible position](#); otherwise, if the user agent has not fired a [timeupdate](#) event at the element in the past 15 to 250ms and is not still running event handlers for such an event, then the user agent must [queue a task](#) to [fire a simple event](#) named [timeupdate](#) at the element.

**Note** Because of the above requirement and the requirement in the [resource fetch algorithm](#) that kicks in when the metadata of the clip becomes known, the [current playback position](#) can never be less than the [earliest possible position](#).

If at any time the user agent learns that an audio or video track has ended and all [media data](#) relating to that track corresponds to parts of the [media timeline](#) that are *before* the [earliest possible position](#), the user agent may [queue a task](#) to first remove the track from the [audioTracks](#) attribute's [AudioTrackList](#) object or the [videoTracks](#) attribute's [VideoTrackList](#) object as appropriate and then [fire](#) a [trusted](#) event with the name [removetrack](#), that does not bubble and is not cancelable, and that uses the [TrackEvent](#) interface, with the [track](#) attribute initialised to the [AudioTrack](#) or [VideoTrack](#) object representing the track, at the [media element](#)'s aforementioned [AudioTrackList](#) or [VideoTrackList](#) object.

The [duration](#) attribute must return the time of the end of the [media resource](#), in seconds, on the [media timeline](#). If no [media data](#) is available, then the attributes must return the Not-a-Number (NaN) value. If the [media resource](#) is not known to be bounded (e.g. streaming radio, or a live event with no announced end time), then the attribute must return the positive Infinity value.

The user agent must determine the duration of the [media resource](#) before playing any part of the [media data](#) and before setting [readyState](#) to a value equal to or greater than [HAVE\\_METADATA](#), even if doing so requires fetching multiple parts of the resource.

When the length of the [media resource](#) changes to a known value (e.g. from being unknown to known, or from a previously established length to a new length) the user agent must [queue a task](#) to [fire a simple event](#) named [durationchange](#) at the [media element](#). (The event is

not fired when the duration is reset as part of loading a new media resource.) If the duration is changed such that the [current playback position](#)<sup>p342</sup> ends up being greater than the time of the end of the [media resource](#)<sup>p328</sup>, then the user agent must also [seek](#)<sup>p351</sup> to the time of the end of the [media resource](#)<sup>p328</sup>.

**Example** If an "infinite" stream ends for some reason, then the duration would change from positive Infinity to the time of the last frame or sample in the stream, and the [durationchange](#)<sup>p387</sup> event would be fired. Similarly, if the user agent initially estimated the [media resource](#)<sup>p328</sup>'s duration instead of determining it precisely, and later revises the estimate based on new information, then the duration would change and the [durationchange](#)<sup>p387</sup> event would be fired.

Some video files also have an explicit date and time corresponding to the zero time in the [media timeline](#)<sup>p341</sup>, known as the **timeline offset**. Initially, the [timeline offset](#)<sup>p343</sup> must be set to Not-a-Number (NaN).

The `getStartDate()` method must return [a new Date object](#)<sup>p50</sup> representing the current [timeline offset](#)<sup>p343</sup>.

The [loop](#) attribute is a [boolean attribute](#)<sup>p59</sup> that, if specified, indicates that the [media element](#)<sup>p326</sup> is to seek back to the start of the [media resource](#)<sup>p328</sup> upon reaching the end.

The [loop](#)<sup>p343</sup> attribute has no effect while the element has a [current media controller](#)<sup>p360</sup>.

The [loop](#) IDL attribute must [reflect](#)<sup>p88</sup> the content attribute of the same name.

#### 4.8.14.7 Ready states

##### Note

`media.readyState`<sup>p345</sup>

Returns a value that expresses the current state of the element with respect to rendering the [current playback position](#)<sup>p342</sup>, from the codes in the list below.

[Media elements](#)<sup>p326</sup> have a *ready state*, which describes to what degree they are ready to be rendered at the [current playback position](#)<sup>p342</sup>. The possible values are as follows; the ready state of a media element at any particular time is the greatest value describing the state of the element:

##### [HAVE NOTHING](#) (numeric value 0)

No information regarding the [media resource](#)<sup>p328</sup> is available. No data for the [current playback position](#)<sup>p342</sup> is available. [Media elements](#)<sup>p326</sup> whose [networkState](#)<sup>p331</sup> attribute are set to [NETWORK\\_EMPTY](#)<sup>p331</sup> are always in the [HAVE NOTHING](#)<sup>p343</sup> state.

##### [HAVE\\_METADATA](#) (numeric value 1)

Enough of the resource has been obtained that the duration of the resource is available. In the case of a [video](#)<sup>p317</sup> element, the dimensions of the video are also available. The API will no longer throw an exception when seeking. No [media data](#)<sup>p328</sup> is available for the immediate [current playback position](#)<sup>p342</sup>.

##### [HAVE\\_CURRENT\\_DATA](#) (numeric value 2)

Data for the immediate [current playback position](#)<sup>p342</sup> is available, but either not enough data is available that the user agent could successfully advance the [current playback position](#)<sup>p342</sup> in the [direction of playback](#)<sup>p348</sup> at all without immediately reverting to the [HAVE\\_METADATA](#)<sup>p343</sup> state, or there is no more data to obtain in the [direction of playback](#)<sup>p348</sup>. For example, in video this corresponds to the user agent having data from the current frame, but not the next frame, when the [current playback position](#)<sup>p342</sup> is at the end of the current frame; and to when [playback has ended](#)<sup>p346</sup>.

##### [HAVE\\_FUTURE\\_DATA](#) (numeric value 3)

Data for the immediate [current playback position](#)<sup>p342</sup> is available, as well as enough data for the user agent to advance the [current playback position](#)<sup>p342</sup> in the [direction of playback](#)<sup>p348</sup> at least a little without immediately reverting to the [HAVE\\_METADATA](#)<sup>p343</sup> state, and [the text tracks are ready](#)<sup>p367</sup>. For example, in video this corresponds to the user agent having data for at least the current frame and the next frame when the [current playback position](#)<sup>p342</sup> is at the instant in time between the two frames, or to the user agent having the video data for the current frame and audio data to keep playing at least a little when the [current playback position](#)<sup>p342</sup> is in the middle of a frame. The user agent cannot be in this state if [playback has ended](#)<sup>p346</sup>, as the [current playback position](#)<sup>p342</sup> can never advance in this case.

#### HAVE ENOUGH DATA (numeric value 4)

All the conditions described for the HAVE FUTURE DATA<sup>p343</sup> state are met, and, in addition, either of the following conditions is also true:

- The user agent estimates that data is being fetched at a rate where the current playback position<sup>p342</sup>, if it were to advance at the effective playback rate<sup>p348</sup>, would not overtake the available data before playback reaches the end of the media resource<sup>p328</sup>.
- The user agent has entered a state where waiting longer will not result in further data being obtained, and therefore nothing would be gained by delaying playback any further. (For example, the buffer might be full.)

**Note**

In practice, the difference between HAVE\_METADATA<sup>p343</sup> and HAVE\_CURRENT\_DATA<sup>p343</sup> is negligible. Really the only time the difference is relevant is when painting a video<sup>p317</sup> element onto a canvas<sup>p607</sup>, where it distinguishes the case where something will be drawn (HAVE\_CURRENT\_DATA<sup>p343</sup> or greater) from the case where nothing is drawn (HAVE\_METADATA<sup>p343</sup> or less). Similarly, the difference between HAVE\_CURRENT\_DATA<sup>p343</sup> (only the current frame) and HAVE\_FUTURE\_DATA<sup>p343</sup> (at least this frame and the next) can be negligible (in the extreme, only one frame). The only time that distinction really matters is when a page provides an interface for "frame-by-frame" navigation.

When the ready state of a media element<sup>p326</sup> whose networkState<sup>p331</sup> is not NETWORK\_EMPTY<sup>p331</sup> changes, the user agent must follow the steps given below:

1. Apply the first applicable set of substeps from the following list:

- ↪ If the previous ready state was HAVE NOTHING<sup>p343</sup>, and the new ready state is HAVE\_METADATA<sup>p343</sup>  
 Queue a task<sup>p835</sup> to fire a simple event<sup>p846</sup> named loadedmetadata<sup>p386</sup> at the element.

**Note** Before this task is run, as part of the event loop<sup>p834</sup> mechanism, the rendering will have been updated to resize the video<sup>p317</sup> element if appropriate.

- ↪ If the previous ready state was HAVE\_METADATA<sup>p343</sup> and the new ready state is HAVE\_CURRENT\_DATA<sup>p343</sup> or greater

If this is the first time this occurs for this media element<sup>p326</sup> since the load()<sup>p331</sup> algorithm was last invoked, the user agent must queue a task<sup>p835</sup> to fire a simple event<sup>p846</sup> named loadeddata<sup>p386</sup> at the element.

If the new ready state is HAVE\_FUTURE\_DATA<sup>p343</sup> or HAVE\_ENOUGH\_DATA<sup>p344</sup>, then the relevant steps below must then be run also.

- ↪ If the previous ready state was HAVE\_FUTURE\_DATA<sup>p343</sup> or more, and the new ready state is HAVE\_CURRENT\_DATA<sup>p343</sup> or less

If the media element<sup>p326</sup> was potentially playing<sup>p346</sup> before its readyState<sup>p345</sup> attribute changed to a value lower than HAVE\_FUTURE\_DATA<sup>p343</sup>, and the element has not ended playback<sup>p346</sup>, and playback has not stopped due to errors<sup>p346</sup>, paused for user interaction<sup>p346</sup>, or paused for in-band content<sup>p346</sup>, the user agent must queue a task<sup>p835</sup> to fire a simple event<sup>p846</sup> named timeupdate<sup>p387</sup> at the element, and queue a task<sup>p835</sup> to fire a simple event<sup>p846</sup> named waiting<sup>p386</sup> at the element.

- ↪ If the previous ready state was HAVE\_CURRENT\_DATA<sup>p343</sup> or less, and the new ready state is HAVE\_FUTURE\_DATA<sup>p343</sup>

The user agent must queue a task<sup>p835</sup> to fire a simple event<sup>p846</sup> named canplay<sup>p386</sup> at the element.

If the element's paused<sup>p346</sup> attribute is false, the user agent must queue a task<sup>p835</sup> to fire a simple event<sup>p846</sup> named playing<sup>p386</sup> at the element.

- ↪ If the new ready state is HAVE\_ENOUGH\_DATA<sup>p344</sup>

If the previous ready state was HAVE\_CURRENT\_DATA<sup>p343</sup> or less, the user agent must queue a task<sup>p835</sup> to fire a simple event<sup>p846</sup> named canplay<sup>p386</sup> at the element, and, if the element's paused<sup>p346</sup> attribute is false, queue a task<sup>p835</sup> to fire a simple event<sup>p846</sup> named playing<sup>p386</sup> at the element.

If the autoplaying flag<sup>p331</sup> is true, and the paused<sup>p346</sup> attribute is true, and the media element<sup>p326</sup> has an autoplay<sup>p345</sup> attribute specified, and the media element<sup>p326</sup>'s node document's active sandboxing flag set<sup>p782</sup> does not have the sandboxed automatic features browsing context flag<sup>p780</sup> set, then the user agent may also run the following substeps:

1. Set the paused<sup>p346</sup> attribute to false.
2. If the element's show poster flag<sup>p342</sup> is true, set it to false and run the time marches on<sup>p349</sup> steps.

3. Queue a task<sup>p835</sup> to fire a simple event<sup>p846</sup> named `play`<sup>p387</sup> at the element.
4. Queue a task<sup>p835</sup> to fire a simple event<sup>p846</sup> named `playing`<sup>p386</sup> at the element.

**Note** User agents do not need to support autoplay, and it is suggested that user agents honor user preferences on the matter. Authors are urged to use the `autoplay`<sup>p345</sup> attribute rather than using script to force the video to play, so as to allow the user to override the behaviour if so desired.

In any case, the user agent must finally queue a task<sup>p835</sup> to fire a simple event<sup>p846</sup> named `canplaythrough`<sup>p386</sup> at the element.

2. If the `media element`<sup>p326</sup> has a `current media controller`<sup>p360</sup>, then report the controller state<sup>p363</sup> for the `media element`<sup>p326</sup>'s `current media controller`<sup>p360</sup>.

**Note** It is possible for the ready state of a media element to jump between these states discontinuously. For example, the state of a media element can jump straight from `HAVE_METADATA`<sup>p343</sup> to `HAVE_ENOUGH_DATA`<sup>p344</sup> without passing through the `HAVE_CURRENT_DATA`<sup>p343</sup> and `HAVE_FUTURE_DATA`<sup>p343</sup> states.

The `readyState` IDL attribute must, on getting, return the value described above that describes the current ready state of the `media element`<sup>p326</sup>.

The `autoplay` attribute is a boolean attribute<sup>p59</sup>. When present, the user agent (as described in the algorithm described herein) will automatically begin playback of the `media resource`<sup>p328</sup> as soon as it can do so without stopping.

**Note** Authors are urged to use the `autoplay`<sup>p345</sup> attribute rather than using script to trigger automatic playback, as this allows the user to override the automatic playback when it is not desired, e.g. when using a screen reader. Authors are also encouraged to consider not using the automatic playback behaviour at all, and instead to let the user agent wait for the user to start playback explicitly.

The `autoplay` IDL attribute must reflect<sup>p88</sup> the content attribute of the same name.

Spec bugs: [28032](#)

#### 4.8.14.8 Playing the media resource

**Note**

`media . paused`<sup>p346</sup>

Returns true if playback is paused; false otherwise.

`media . ended`<sup>p346</sup>

Returns true if playback has reached the end of the `media resource`<sup>p328</sup>.

`media . defaultPlaybackRate`<sup>p347</sup> [= `value`]

Returns the default rate of playback, for when the user is not fast-forwarding or reversing through the `media resource`<sup>p328</sup>.

Can be set, to change the default rate of playback.

The default rate has no direct effect on playback, but if the user switches to a fast-forward mode, when they return to the normal playback mode, it is expected that the rate of playback will be returned to the default rate of playback.

When the element has a `current media controller`<sup>p360</sup>, the `defaultPlaybackRate`<sup>p347</sup> attribute is ignored and the `current media controller`<sup>p360</sup>'s `defaultPlaybackRate`<sup>p361</sup> is used instead.

`media . playbackRate`<sup>p347</sup> [= `value`]

Returns the current rate playback, where 1.0 is normal speed.

Can be set, to change the rate of playback.

When the element has a `current media controller`<sup>p360</sup>, the `playbackRate`<sup>p347</sup> attribute is ignored and the `current media controller`<sup>p360</sup>'s `playbackRate`<sup>p361</sup> is used instead.

`media . played`<sup>p347</sup>

Returns a `TimeRanges`<sup>p384</sup> object that represents the ranges of the `media resource`<sup>p328</sup> that the user agent has played.

:

`media . playp347()`

Sets the `pausedp346` attribute to false, loading the `media resourcep328` and beginning playback if necessary. If the playback had ended, will restart it from the start.

`media . pausep348()`

Sets the `pausedp346` attribute to true, loading the `media resourcep328` if necessary.

The `paused` attribute represents whether the `media elementp326` is paused or not. The attribute must initially be true.

A `media elementp326` is a **blocked media element** if its `readyStatep345` attribute is in the `HAVE NOTHINGp343` state, the `HAVE_METADATAp343` state, or the `HAVE_CURRENT_DATAp343` state, or if the element has `paused for user interactionp346` or `paused for in-band contentp346`.

A `media elementp326` is said to be **potentially playing** when its `pausedp346` attribute is false, the element has not `ended playbackp346`, playback has not `stopped due to errorsp346`, the element either has no `current media controllerp360` or has a `current media controllerp360` but is not `blocked on its media controllerp362`, and the element is not a `blocked media elementp346`.

**Note** A `waitingp346` DOM event can be fired<sup>p344</sup> as a result of an element that is potentially playing<sup>p346</sup> stopping playback due to its `readyStatep345` attribute changing to a value lower than `HAVE_FUTURE_DATAp343`.

A `media elementp326` is said to have **ended playback** when:

- The element's `readyStatep345` attribute is `HAVE_METADATAp343` or greater, and
- Either:
  - The `current playback positionp342` is the end of the `media resourcep328`, and
  - The `direction of playbackp348` is forwards, and
  - Either the `media elementp326` does not have a `loopp343` attribute specified, or the `media elementp326` has a `current media controllerp360`.

Or:

- The `current playback positionp342` is the `earliest possible positionp342`, and
- The `direction of playbackp348` is backwards.

The `ended` attribute must return true if, the last time the `event loopp834` reached `step 1p836`, the `media elementp326` had `ended playbackp346` and the `direction of playbackp348` was forwards, and false otherwise.

A `media elementp326` is said to have **stopped due to errors** when the element's `readyStatep345` attribute is `HAVE_METADATAp343` or greater, and the user agent `encounters a non-fatal errorp339` during the processing of the `media datap328`, and due to that error, is not able to play the content at the `current playback positionp342`.

A `media elementp326` is said to have **paused for user interaction** when its `pausedp346` attribute is false, the `readyStatep345` attribute is either `HAVE_FUTURE_DATAp343` or `HAVE_ENOUGH_DATAp344` and the user agent has reached a point in the `media resourcep328` where the user has to make a selection for the resource to continue. If the `media elementp326` has a `current media controllerp360` when this happens, then the user agent must `report the controller statep363` for the `media elementp326`'s `current media controllerp360`. If the `media elementp326` has a `current media controllerp360` when the user makes a selection, allowing playback to resume, the user agent must similarly `report the controller statep363` for the `media elementp326`'s `current media controllerp360`.

It is possible for a `media elementp326` to have both `ended playbackp346` and `paused for user interactionp346` at the same time.

When a `media elementp326` that is `potentially playingp346` stops playing because it has `paused for user interactionp346`, the user agent must `queue a taskp835` to fire a simple event<sup>p846</sup> named `timeupdatep387` at the element.

A `media elementp326` is said to have **paused for in-band content** when its `pausedp346` attribute is false, the `readyStatep345` attribute is either `HAVE_FUTURE_DATAp343` or `HAVE_ENOUGH_DATAp344` and the user agent has suspended playback of the `media resourcep328` in order to play content that is temporally anchored to the `media resourcep328` and has a non-zero length, or to play content that is temporally anchored to a

segment of the [media resource](#)<sup>p328</sup> but has a length longer than that segment. If the [media element](#)<sup>p326</sup> has a [current media controller](#)<sup>p360</sup> when this happens, then the user agent must [report the controller state](#)<sup>p363</sup> for the [media element](#)<sup>p326</sup>'s [current media controller](#)<sup>p360</sup>. If the [media element](#)<sup>p326</sup> has a [current media controller](#)<sup>p360</sup> when the user agent unsuspends playback, the user agent must similarly [report the controller state](#)<sup>p363</sup> for the [media element](#)<sup>p326</sup>'s [current media controller](#)<sup>p360</sup>.

**Example** One example of when a [media element](#)<sup>p326</sup> would be [paused for in-band content](#)<sup>p346</sup> is when the user agent is playing [audio descriptions](#)<sup>p325</sup> from an external WebVTT file, and the synthesized speech generated for a cue is longer than the time between the [text track cue start time](#)<sup>p368</sup> and the [text track cue end time](#)<sup>p368</sup>.

When the [current playback position](#)<sup>p342</sup> reaches the end of the [media resource](#)<sup>p328</sup> when the [direction of playback](#)<sup>p348</sup> is forwards, then the user agent must follow these steps:

1. If the [media element](#)<sup>p326</sup> has a [loop](#)<sup>p343</sup> attribute specified and does not have a [current media controller](#)<sup>p360</sup>, then [seek](#)<sup>p351</sup> to the [earliest possible position](#)<sup>p342</sup> of the [media resource](#)<sup>p328</sup> and abort these steps.
2. As defined above, the [ended](#)<sup>p346</sup> IDL attribute starts returning true once the [event loop](#)<sup>p834</sup> returns to [step 1](#)<sup>p836</sup>.
3. [Queue a task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> named [timeupdate](#)<sup>p387</sup> at the [media element](#)<sup>p326</sup>.
4. [Queue a task](#)<sup>p835</sup> that, if the [media element](#)<sup>p326</sup> does not have a [current media controller](#)<sup>p360</sup>, and the [media element](#)<sup>p326</sup> has still [ended playback](#)<sup>p346</sup>, and the [direction of playback](#)<sup>p348</sup> is still forwards, and [paused](#)<sup>p346</sup> is false, changes [paused](#)<sup>p346</sup> to true and [fires a simple event](#)<sup>p846</sup> named [pause](#)<sup>p387</sup> at the [media element](#)<sup>p326</sup>.
5. [Queue a task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> named [ended](#)<sup>p386</sup> at the [media element](#)<sup>p326</sup>.
6. If the [media element](#)<sup>p326</sup> has a [current media controller](#)<sup>p360</sup>, then [report the controller state](#)<sup>p363</sup> for the [media element](#)<sup>p326</sup>'s [current media controller](#)<sup>p360</sup>.

When the [current playback position](#)<sup>p342</sup> reaches the [earliest possible position](#)<sup>p342</sup> of the [media resource](#)<sup>p328</sup> when the [direction of playback](#)<sup>p348</sup> is backwards, then the user agent must only [queue a task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> named [timeupdate](#)<sup>p387</sup> at the element.

**Note** The word "reaches" here does not imply that the [current playback position](#)<sup>p342</sup> needs to have changed during normal playback; it could be via [seeking](#)<sup>p351</sup>, for instance.

The [defaultPlaybackRate](#) attribute gives the desired speed at which the [media resource](#)<sup>p328</sup> is to play, as a multiple of its intrinsic speed. The attribute is mutable: on getting it must return the last value it was set to, or 1.0 if it hasn't yet been set; on setting the attribute must be set to the new value.

**Note** The [defaultPlaybackRate](#)<sup>p347</sup> is used by the user agent when it exposes a user interface to the user<sup>p382</sup>.

The [playbackRate](#) attribute gives the [effective playback rate](#)<sup>p348</sup> (assuming there is no [current media controller](#)<sup>p360</sup> overriding it), which is the speed at which the [media resource](#)<sup>p328</sup> plays, as a multiple of its intrinsic speed. If it is not equal to the [defaultPlaybackRate](#)<sup>p347</sup>, then the implication is that the user is using a feature such as fast forward or slow motion playback. The attribute is mutable: on getting it must return the last value it was set to, or 1.0 if it hasn't yet been set; on setting the attribute must be set to the new value, and the playback will change speed (if the element is [potentially playing](#)<sup>p346</sup> and there is no [current media controller](#)<sup>p360</sup>).

When the [defaultPlaybackRate](#)<sup>p347</sup> or [playbackRate](#)<sup>p347</sup> attributes change value (either by being set by script or by being changed directly by the user agent, e.g. in response to user control) the user agent must [queue a task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> named [ratechange](#)<sup>p387</sup> at the [media element](#)<sup>p326</sup>.

**Note** The [defaultPlaybackRate](#)<sup>p347</sup> and [playbackRate](#)<sup>p347</sup> attributes have no effect when the [media element](#)<sup>p326</sup> has a [current media controller](#)<sup>p360</sup>; the namesake attributes on the [MediaController](#)<sup>p358</sup> object are used instead in that situation.

The [played](#) attribute must return a new static [normalised TimeRanges](#) object<sup>p385</sup> that represents the ranges of points on the [media timeline](#)<sup>p341</sup> of the [media resource](#)<sup>p328</sup> reached through the usual monotonic increase of the [current playback position](#)<sup>p342</sup> during normal playback, if any, at the time the attribute is evaluated.

When the [play\(\)](#) method on a [media element](#)<sup>p326</sup> is invoked, the user agent must run the following steps.

1. If the [media element](#)<sup>p326</sup>'s [networkState](#)<sup>p331</sup> attribute has the value [NETWORK\\_EMPTY](#)<sup>p331</sup>, invoke the [media element](#)<sup>p326</sup>'s [resource selection algorithm](#)<sup>p332</sup>.
  2. If the [playback has ended](#)<sup>p346</sup> and the [direction of playback](#)<sup>p348</sup> is forwards, and the [media element](#)<sup>p326</sup> does not have a [current media controller](#)<sup>p360</sup>, [seek](#)<sup>p351</sup> to the [earliest possible position](#)<sup>p342</sup> of the [media resource](#)<sup>p328</sup>.
- Note** *This will cause*<sup>p352</sup> *the user agent to queue a task*<sup>p835</sup> *to fire a simple event*<sup>p846</sup> *named* [\*timeupdate\*](#)<sup>p387</sup> *at the media element*<sup>p326</sup>.
3. If the [media element](#)<sup>p326</sup> has a [current media controller](#)<sup>p360</sup>, then [bring the media element up to speed with its new media controller](#)<sup>p362</sup>.
  4. If the [media element](#)<sup>p326</sup>'s [paused](#)<sup>p346</sup> attribute is true, run the following substeps:
    1. Change the value of [paused](#)<sup>p346</sup> to false.
    2. If the [show poster flag](#)<sup>p342</sup> is true, set the element's [show poster flag](#)<sup>p342</sup> to false and run the [time marches on](#)<sup>p349</sup> steps.
    3. [Queue a task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> named [\*play\*](#)<sup>p387</sup> at the element.
    4. If the [media element](#)<sup>p326</sup>'s [readyState](#)<sup>p345</sup> attribute has the value [HAVE NOTHING](#)<sup>p343</sup>, [HAVE\\_METADATA](#)<sup>p343</sup>, or [HAVE\\_CURRENT\\_DATA](#)<sup>p343</sup>, [queue a task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> named [\*waiting\*](#)<sup>p386</sup> at the element.  
Otherwise, the [media element](#)<sup>p326</sup>'s [readyState](#)<sup>p345</sup> attribute has the value [HAVE\\_FUTURE\\_DATA](#)<sup>p343</sup> or [HAVE\\_ENOUGH\\_DATA](#)<sup>p344</sup>: [queue a task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> named [\*playing\*](#)<sup>p386</sup> at the element.
  5. Set the [media element](#)<sup>p326</sup>'s [autoplaying flag](#)<sup>p331</sup> to false.
  6. If the [media element](#)<sup>p326</sup> has a [current media controller](#)<sup>p360</sup>, then [report the controller state](#)<sup>p363</sup> for the [media element](#)<sup>p326</sup>'s [current media controller](#)<sup>p360</sup>.

When the [pause\(\)](#) method is invoked, and when the user agent is required to pause the [media element](#)<sup>p326</sup>, the user agent must run the following steps:

1. If the [media element](#)<sup>p326</sup>'s [networkState](#)<sup>p331</sup> attribute has the value [NETWORK\\_EMPTY](#)<sup>p331</sup>, invoke the [media element](#)<sup>p326</sup>'s [resource selection algorithm](#)<sup>p332</sup>.
2. Run the [internal pause steps](#)<sup>p348</sup> for the [media element](#)<sup>p326</sup>.

The [internal pause steps](#) for a [media element](#)<sup>p326</sup> are as follows:

Spec bugs: [28125](#) :

1. Set the [media element](#)<sup>p326</sup>'s [autoplaying flag](#)<sup>p331</sup> to false.
2. If the [media element](#)<sup>p326</sup>'s [paused](#)<sup>p346</sup> attribute is false, run the following steps:
  1. Change the value of [paused](#)<sup>p346</sup> to true.
  2. [Queue a task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> named [\*timeupdate\*](#)<sup>p387</sup> at the element.
  3. [Queue a task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> named [\*pause\*](#)<sup>p387</sup> at the element.
  4. Set the [official playback position](#)<sup>p342</sup> to the [current playback position](#)<sup>p342</sup>.
3. If the [media element](#)<sup>p326</sup> has a [current media controller](#)<sup>p360</sup>, then [report the controller state](#)<sup>p363</sup> for the [media element](#)<sup>p326</sup>'s [current media controller](#)<sup>p360</sup>.

The [effective playback rate](#) is not necessarily the element's [playbackRate](#)<sup>p347</sup>. When a [media element](#)<sup>p326</sup> has a [current media controller](#)<sup>p360</sup>, its [effective playback rate](#)<sup>p348</sup> is the [MediaController](#)<sup>p358</sup>'s [media controller playback rate](#)<sup>p361</sup>. Otherwise, the [effective playback rate](#)<sup>p348</sup> is just the element's [playbackRate](#)<sup>p347</sup>. Thus, the [current media controller](#)<sup>p360</sup> overrides the [media element](#)<sup>p326</sup>.

If the [effective playback rate](#)<sup>p348</sup> is positive or zero, then the [direction of playback](#) is forwards. Otherwise, it is backwards.

When a [media element](#)<sup>p326</sup> is [potentially playing](#)<sup>p346</sup> and its [Document](#)<sup>p102</sup> is a [fully active](#)<sup>p763</sup> [Document](#)<sup>p102</sup>, its [current playback position](#)<sup>p342</sup> must increase monotonically at [effective playback rate](#)<sup>p348</sup> units of media time per unit time of the [media timeline](#)<sup>p341</sup>'s clock. (This specification always refers to this as an *increase*, but that increase could actually be a *decrease* if the [effective playback rate](#)<sup>p348</sup> is negative.)

**Note** *The [effective playback rate](#)<sup>p348</sup> can be 0.0, in which case the [current playback position](#)<sup>p342</sup> doesn't move, despite playback not being paused ([paused](#)<sup>p346</sup> doesn't become true, and the [pause](#)<sup>p387</sup> event doesn't fire).*

**Note** *This specification doesn't define how the user agent achieves the appropriate playback rate — depending on the protocol and media available, it is plausible that the user agent could negotiate with the server to have the server provide the media data at the appropriate rate, so that (except for the period between when the rate is changed and when the server updates the stream's playback rate) the client doesn't actually have to drop or interpolate any frames.*

Any time the user agent [provides a stable state](#)<sup>p337</sup>, the [official playback position](#)<sup>p342</sup> must be set to the [current playback position](#)<sup>p342</sup>.

While the [direction of playback](#)<sup>p348</sup> is backwards, any corresponding audio must be [muted](#)<sup>p383</sup>. While the [effective playback rate](#)<sup>p348</sup> is so low or so high that the user agent cannot play audio usefully, the corresponding audio must also be [muted](#)<sup>p383</sup>. If the [effective playback rate](#)<sup>p348</sup> is not 1.0, the user agent may apply pitch adjustments to the audio as necessary to render it faithfully.

[Media elements](#)<sup>p326</sup> that are [potentially playing](#)<sup>p346</sup> while not [in a Document](#)<sup>p42</sup> must not play any video, but should play any audio component. Media elements must not stop playing just because all references to them have been removed; only once a media element is in a state where no further audio could ever be played by that element may the element be garbage collected.

**Note** *It is possible for an element to which no explicit references exist to play audio, even if such an element is not still actively playing: for instance, it could have a [current media controller](#)<sup>p360</sup> that still has references and can still be unpause, or it could be unpause but stalled waiting for content to buffer, or it could be still buffering, but with a [suspend](#)<sup>p386</sup> event listener that begins playback. Even a media element whose [media resource](#)<sup>p328</sup> has no audio tracks could eventually play audio again if it had an event listener that changes the [media resource](#)<sup>p328</sup>.*

Each [media element](#)<sup>p326</sup> has a [list of newly introduced cues](#), which must be initially empty. Whenever a [text track cue](#)<sup>p368</sup> is added to the [list of cues](#)<sup>p367</sup> of a [text track](#)<sup>p365</sup> that is in the [list of text tracks](#)<sup>p365</sup> for a [media element](#)<sup>p326</sup>, that [cue](#)<sup>p368</sup> must be added to the [media element](#)<sup>p326</sup>'s [list of newly introduced cues](#)<sup>p349</sup>. Whenever a [text track](#)<sup>p365</sup> is added to the [list of text tracks](#)<sup>p365</sup> for a [media element](#)<sup>p326</sup>, all of the [cues](#)<sup>p368</sup> in that [text track](#)<sup>p365</sup>'s [list of cues](#)<sup>p367</sup> must be added to the [media element](#)<sup>p326</sup>'s [list of newly introduced cues](#)<sup>p349</sup>. When a [media element](#)<sup>p326</sup>'s [list of newly introduced cues](#)<sup>p349</sup> has new cues added while the [media element](#)<sup>p326</sup>'s [show poster flag](#)<sup>p342</sup> is not set, then the user agent must run the [time marches on](#)<sup>p349</sup> steps.

When a [text track cue](#)<sup>p368</sup> is removed from the [list of cues](#)<sup>p367</sup> of a [text track](#)<sup>p365</sup> that is in the [list of text tracks](#)<sup>p365</sup> for a [media element](#)<sup>p326</sup>, and whenever a [text track](#)<sup>p365</sup> is removed from the [list of text tracks](#)<sup>p365</sup> of a [media element](#)<sup>p326</sup>, if the [media element](#)<sup>p326</sup>'s [show poster flag](#)<sup>p342</sup> is not set, then the user agent must run the [time marches on](#)<sup>p349</sup> steps.

When the [current playback position](#)<sup>p342</sup> of a [media element](#)<sup>p326</sup> changes (e.g. due to playback or seeking), the user agent must run the [time marches on](#)<sup>p349</sup> steps. If the [current playback position](#)<sup>p342</sup> changes while the steps are running, then the user agent must wait for the steps to complete, and then must immediately rerun the steps. (These steps are thus run as often as possible or needed — if one iteration takes a long time, this can cause certain [cues](#)<sup>p368</sup> to be skipped over as the user agent rushes ahead to "catch up".)

The [time marches on](#) steps are as follows:

1. Let *current cues* be a list of [cues](#)<sup>p368</sup>, initialised to contain all the [cues](#)<sup>p368</sup> of all the [hidden](#)<sup>p367</sup> or [showing](#)<sup>p367</sup> [text tracks](#)<sup>p365</sup> of the [media element](#)<sup>p326</sup> (not the [disabled](#)<sup>p367</sup> ones) whose [start times](#)<sup>p368</sup> are less than or equal to the [current playback position](#)<sup>p342</sup> and whose [end times](#)<sup>p368</sup> are greater than the [current playback position](#)<sup>p342</sup>.
2. Let *other cues* be a list of [cues](#)<sup>p368</sup>, initialised to contain all the [cues](#)<sup>p368</sup> of [hidden](#)<sup>p367</sup> and [showing](#)<sup>p367</sup> [text tracks](#)<sup>p365</sup> of the [media element](#)<sup>p326</sup> that are not present in *current cues*.
3. Let *last time* be the [current playback position](#)<sup>p342</sup> at the time this algorithm was last run for this [media element](#)<sup>p326</sup>, if this is not the first time it has run.
4. If the [current playback position](#)<sup>p342</sup> has, since the last time this algorithm was run, only changed through its usual monotonic increase during normal playback, then let *missed cues* be the list of [cues](#)<sup>p368</sup> in *other cues* whose [start times](#)<sup>p368</sup> are greater than or equal to *last time* and whose [end times](#)<sup>p368</sup> are less than or equal to the [current playback position](#)<sup>p342</sup>. Otherwise, let *missed cues* be an empty list.
5. Remove all the [cues](#)<sup>p368</sup> in *missed cues* that are also in the [media element](#)<sup>p326</sup>'s [list of newly introduced cues](#)<sup>p349</sup>, and then empty the element's [list of newly introduced cues](#)<sup>p349</sup>.

- If the time was reached through the usual monotonic increase of the [current playback position](#)<sup>p342</sup> during normal playback, and if the user agent has not fired a [timeupdate](#)<sup>p387</sup> event at the element in the past 15 to 250ms and is not still running event handlers for such an event, then the user agent must [queue a task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> named [timeupdate](#)<sup>p387</sup> at the element. (In the other cases, such as explicit seeks, relevant events get fired as part of the overall process of changing the [current playback position](#)<sup>p342</sup>.)

**Note** *The event thus is not to be fired faster than about 66Hz or slower than 4Hz (assuming the event handlers don't take longer than 250ms to run). User agents are encouraged to vary the frequency of the event based on the system load and the average cost of processing the event each time, so that the UI updates are not any more frequent than the user agent can comfortably handle while decoding the video.*

- If all of the [cues](#)<sup>p368</sup> in [current cues](#) have their [text track cue active flag](#)<sup>p368</sup> set, none of the [cues](#)<sup>p368</sup> in [other cues](#) have their [text track cue active flag](#)<sup>p368</sup> set, and [missed cues](#) is empty, then abort these steps.
- If the time was reached through the usual monotonic increase of the [current playback position](#)<sup>p342</sup> during normal playback, and there are [cues](#)<sup>p368</sup> in [other cues](#) that have their [text track cue pause-on-exit flag](#)<sup>p368</sup> set and that either have their [text track cue active flag](#)<sup>p368</sup> set or are also in [missed cues](#), then [immediately](#)<sup>p41</sup> [pause](#)<sup>p348</sup> the [media element](#)<sup>p326</sup>.

**Note** *In the other cases, such as explicit seeks, playback is not paused by going past the end time of a cue<sup>p368</sup>, even if that cue<sup>p368</sup> has its [text track cue pause-on-exit flag](#)<sup>p368</sup> set.*

- Let [events](#) be a list of [tasks](#)<sup>p834</sup>, initially empty. Each [task](#)<sup>p834</sup> in this list will be associated with a [text track](#)<sup>p365</sup>, a [text track cue](#)<sup>p368</sup>, and a time, which are used to sort the list before the [tasks](#)<sup>p834</sup> are queued.

Let [affected tracks](#) be a list of [text tracks](#)<sup>p365</sup>, initially empty.

When the steps below say to [prepare an event](#) named [event](#) for a [text track cue](#)<sup>p368</sup> target with a time [time](#), the user agent must run these substeps:

- Let [track](#) be the [text track](#)<sup>p365</sup> with which the [text track cue](#)<sup>p368</sup> target is associated.
- Create a [task](#)<sup>p834</sup> to [fire a simple event](#)<sup>p846</sup> named [event](#) at [target](#).
- Add the newly created [task](#)<sup>p834</sup> to [events](#), associated with the time [time](#), the [text track](#)<sup>p365</sup> [track](#), and the [text track cue](#)<sup>p368</sup> [target](#).
- Add [track](#) to [affected tracks](#).
- For each [text track cue](#)<sup>p368</sup> in [missed cues](#), [prepare an event](#)<sup>p350</sup> named [enter](#)<sup>p387</sup> for the [TextTrackCue](#)<sup>p378</sup> object with the [text track cue start time](#)<sup>p368</sup>.
- For each [text track cue](#)<sup>p368</sup> in [other cues](#) that either has its [text track cue active flag](#)<sup>p368</sup> set or is in [missed cues](#), [prepare an event](#)<sup>p350</sup> named [exit](#)<sup>p387</sup> for the [TextTrackCue](#)<sup>p378</sup> object with the later of the [text track cue end time](#)<sup>p368</sup> and the [text track cue start time](#)<sup>p368</sup>.
- For each [text track cue](#)<sup>p368</sup> in [current cues](#) that does not have its [text track cue active flag](#)<sup>p368</sup> set, [prepare an event](#)<sup>p350</sup> named [enter](#)<sup>p387</sup> for the [TextTrackCue](#)<sup>p378</sup> object with the [text track cue start time](#)<sup>p368</sup>.
- Sort the [tasks](#)<sup>p834</sup> in [events](#) in ascending time order ([tasks](#)<sup>p834</sup> with earlier times first).

Further sort [tasks](#)<sup>p834</sup> in [events](#) that have the same time by the relative [text track cue order](#)<sup>p368</sup> of the [text track cues](#)<sup>p368</sup> associated with these [tasks](#)<sup>p834</sup>.

Finally, sort [tasks](#)<sup>p834</sup> in [events](#) that have the same time and same [text track cue order](#)<sup>p368</sup> by placing [tasks](#)<sup>p834</sup> that fire [enter](#)<sup>p387</sup> events before those that fire [exit](#)<sup>p387</sup> events.

- [Queue](#)<sup>p835</sup> each [task](#)<sup>p834</sup> in [events](#), in list order.
- Sort [affected tracks](#) in the same order as the [text tracks](#)<sup>p365</sup> appear in the [media element](#)<sup>p326</sup>'s [list of text tracks](#)<sup>p365</sup>, and remove duplicates.
- For each [text track](#)<sup>p365</sup> in [affected tracks](#), in the list order, [queue a task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> named [cuechange](#)<sup>p387</sup> at the [TextTrack](#)<sup>p374</sup> object, and, if the [text track](#)<sup>p365</sup> has a corresponding [track](#)<sup>p324</sup> element, to then [fire a simple event](#)<sup>p846</sup> named [cuechange](#)<sup>p387</sup> at the [track](#)<sup>p324</sup> element as well.
- Set the [text track cue active flag](#)<sup>p368</sup> of all the [cues](#)<sup>p368</sup> in the [current cues](#), and unset the [text track cue active flag](#)<sup>p368</sup> of all the [cues](#)<sup>p368</sup> in the [other cues](#).

18. Run the [rules for updating the text track rendering](#)<sup>p367</sup> of each of the [text tracks](#)<sup>p365</sup> in [affected tracks](#) that are [showing](#)<sup>p367</sup>. For example, for [text tracks](#)<sup>p365</sup> based on WebVTT, the [rules for updating the display of WebVTT text tracks](#)<sup>p54</sup>. [\[WEBVTT\]](#)<sup>p1154</sup>

For the purposes of the algorithm above, a [text track cue](#)<sup>p368</sup> is considered to be part of a [text track](#)<sup>p365</sup> only if it is listed in the [text track list of cues](#)<sup>p367</sup>, not merely if it is associated with the [text track](#)<sup>p365</sup>.

**Note** If the [media element](#)<sup>p326</sup>'s [node document](#) stops being a [fully active](#)<sup>p763</sup> document, then the playback will [stop](#)<sup>p349</sup> until the document is active again.

When a [media element](#)<sup>p326</sup> is [removed from a Document](#)<sup>p42</sup>, the user agent must run the following steps:

1. [Await a stable state](#)<sup>p837</sup>, allowing the [task](#)<sup>p834</sup> that removed the [media element](#)<sup>p326</sup> from the [Document](#)<sup>p102</sup> to continue. The [synchronous section](#)<sup>p837</sup> consists of all the remaining steps of this algorithm. (Steps in the [synchronous section](#)<sup>p837</sup> are marked with  $\mathbb{X}$ .)
2.  $\mathbb{X}$  If the [media element](#)<sup>p326</sup> is [in a Document](#)<sup>p42</sup>, abort these steps.
3.  $\mathbb{X}$  Run the [internal pause steps](#)<sup>p348</sup> for the [media element](#)<sup>p326</sup>.

#### 4.8.14.9 Seeking

**Note**

**media . seeking**<sup>p351</sup>

Returns true if the user agent is currently seeking.

**media . seekable**<sup>p352</sup>

Returns a [TimeRanges](#)<sup>p384</sup> object that represents the ranges of the [media resource](#)<sup>p328</sup> to which it is possible for the user agent to seek.

**media . fastSeek**<sup>p351</sup>( *time* )

Seeks to near the given *time* as fast as possible, trading precision for speed. (To seek to a precise time, use the [currentTime](#)<sup>p342</sup> attribute.)

This does nothing if the media resource has not been loaded.

The [seeking](#) attribute must initially have the value false.

The [fastSeek\(\)](#) method must [seek](#)<sup>p351</sup> to the time given by the method's argument, with the [approximate-for-speed](#) flag set.

When the user agent is required to [seek](#) to a particular *new playback position* in the [media resource](#)<sup>p328</sup>, optionally with the [approximate-for-speed](#) flag set, it means that the user agent must run the following steps. This algorithm interacts closely with the [event loop](#)<sup>p834</sup> mechanism; in particular, it has a [synchronous section](#)<sup>p837</sup> (which is triggered as part of the [event loop](#)<sup>p834</sup> algorithm). Steps in that section are marked with  $\mathbb{X}$ .

1. Set the [media element](#)<sup>p326</sup>'s [show poster flag](#)<sup>p342</sup> to false.
2. If the [media element](#)<sup>p326</sup>'s [readyState](#)<sup>p345</sup> is [HAVE NOTHING](#)<sup>p343</sup>, abort these steps.
3. If the element's [seeking](#)<sup>p351</sup> IDL attribute is true, then another instance of this algorithm is already running. Abort that other instance of the algorithm without waiting for the step that it is running to complete.
4. Set the [seeking](#)<sup>p351</sup> IDL attribute to true.
5. If the seek was in response to a DOM method call or setting of an IDL attribute, then continue the script. The remainder of these steps must be run [in parallel](#)<sup>p41</sup>. With the exception of the steps marked with  $\mathbb{X}$ , they could be aborted at any time by another instance of this algorithm being invoked.
6. If the *new playback position* is later than the end of the [media resource](#)<sup>p328</sup>, then let it be the end of the [media resource](#)<sup>p328</sup> instead.
7. If the *new playback position* is less than the [earliest possible position](#)<sup>p342</sup>, let it be that position instead.
8. If the (possibly now changed) *new playback position* is not in one of the ranges given in the [seekable](#)<sup>p352</sup> attribute, then let it be the position in one of the ranges given in the [seekable](#)<sup>p352</sup> attribute that is the nearest to the *new playback position*. If two positions both

satisfy that constraint (i.e. the *new playback position* is exactly in the middle between two ranges in the `seekable`<sup>p352</sup> attribute) then use the position that is closest to the `current playback position`<sup>p342</sup>. If there are no ranges given in the `seekable`<sup>p352</sup> attribute then set the `seeking`<sup>p351</sup> IDL attribute to false and abort these steps.

9. If the *approximate-for-speed* flag is set, adjust the *new playback position* to a value that will allow for playback to resume promptly. If *new playback position* before this step is before `current playback position`<sup>p342</sup>, then the adjusted *new playback position* must also be before the `current playback position`<sup>p342</sup>. Similarly, if the *new playback position* before this step is after `current playback position`<sup>p342</sup>, then the adjusted *new playback position* must also be after the `current playback position`<sup>p342</sup>.

**Example** For example, the user agent could snap to a nearby key frame, so that it doesn't have to spend time decoding then discarding intermediate frames before resuming playback.

10. Queue a task<sup>p835</sup> to fire a simple event<sup>p846</sup> named `seeking`<sup>p386</sup> at the element.

11. Set the `current playback position`<sup>p342</sup> to the *new playback position*.

**Note** If the `media element`<sup>p326</sup> was *potentially playing*<sup>p346</sup> immediately before it started seeking, but seeking caused its `readyState`<sup>p345</sup> attribute to change to a value lower than `HAVE FUTURE DATA`<sup>p343</sup>, then a `waiting`<sup>p386</sup> event *will be fired*<sup>p344</sup> at the element.

**Note** This step sets the `current playback position`<sup>p342</sup>, and thus can immediately trigger other conditions, such as the rules regarding when playback "reaches the end of the media resource"<sup>p347</sup> (part of the logic that handles looping), even before the user agent is actually able to render the media data for that position (as determined in the next step).

**Note** The `currentTime`<sup>p342</sup> attribute returns the *official playback position*<sup>p342</sup>, not the `current playback position`<sup>p342</sup>, and therefore gets updated before script execution, separate from this algorithm.

12. Wait until the user agent has established whether or not the `media data`<sup>p328</sup> for the *new playback position* is available, and, if it is, until it has decoded enough data to play back that position.

13. Await a stable state<sup>p837</sup>. The `synchronous section`<sup>p837</sup> consists of all the remaining steps of this algorithm. (Steps in the `synchronous section`<sup>p837</sup> are marked with  $\mathbb{X}$ .)

14.  $\mathbb{X}$  Set the `seeking`<sup>p351</sup> IDL attribute to false.

15.  $\mathbb{X}$  Run the `time marches on`<sup>p349</sup> steps.

16.  $\mathbb{X}$  Queue a task<sup>p835</sup> to fire a simple event<sup>p846</sup> named `timeupdate`<sup>p387</sup> at the element.

17.  $\mathbb{X}$  Queue a task<sup>p835</sup> to fire a simple event<sup>p846</sup> named `seeked`<sup>p386</sup> at the element.

The `seekable` attribute must return a new static `normalised TimeRanges object`<sup>b385</sup> that represents the ranges of the `media resource`<sup>p328</sup>, if any, that the user agent is able to seek to, at the time the attribute is evaluated.

**Note** If the user agent can seek to anywhere in the `media resource`<sup>p328</sup>, e.g. because it is a simple movie file and the user agent and the server support HTTP Range requests, then the attribute would return an object with one range, whose start is the time of the first frame (the *earliest possible position*<sup>p342</sup>, typically zero), and whose end is the same as the time of the first frame plus the `duration`<sup>p342</sup> attribute's value (which would equal the time of the last frame, and might be positive Infinity).

**Note** The range might be continuously changing, e.g. if the user agent is buffering a sliding window on an infinite stream. This is the behaviour seen with DVRs viewing live TV, for instance.

User agents should adopt a very liberal and optimistic view of what is seekable. User agents should also buffer recent content where possible to enable seeking to be fast.

**Example** For instance, consider a large video file served on an HTTP server without support for HTTP Range requests. A browser could implement this by only buffering the current frame and data obtained for subsequent frames, never allow seeking, except for seeking to the very start by restarting the playback. However, this would be a poor implementation. A high quality implementation would buffer the last few minutes of content (or more, if sufficient storage space is available), allowing the user to jump back and rewatch something surprising without any latency, and would in addition allow arbitrary seeking by reloading the file from the start if necessary, which would be slower but still more convenient than having to literally restart the video and watch it all the way through just to get to an earlier unbuffered spot.

[Media resources](#)<sup>p328</sup> might be internally scripted or interactive. Thus, a [media element](#)<sup>p326</sup> could play in a non-linear fashion. If this happens, the user agent must act as if the algorithm for [seeking](#)<sup>p351</sup> was used whenever the [current playback position](#)<sup>p342</sup> changes in a discontinuous fashion (so that the relevant events fire). If the [media element](#)<sup>p326</sup> has a [current media controller](#)<sup>p360</sup>, then the user agent must [seek the media controller](#)<sup>p362</sup> appropriately instead.

#### 4.8.14.10 Media resources with multiple media tracks

A [media resource](#)<sup>p328</sup> can have multiple embedded audio and video tracks. For example, in addition to the primary video and audio tracks, a [media resource](#)<sup>p328</sup> could have foreign-language dubbed dialogues, director's commentaries, audio descriptions, alternative angles, or sign-language overlays.

##### Note

`media.audioTracksp353`

Returns an [AudioTrackList](#)<sup>p354</sup> object representing the audio tracks available in the [media resource](#)<sup>p328</sup>.

`media.videoTracksp353`

Returns a [VideoTrackList](#)<sup>p354</sup> object representing the video tracks available in the [media resource](#)<sup>p328</sup>.

The `audioTracks` attribute of a [media element](#)<sup>p326</sup> must return a [live](#)<sup>p43</sup> [AudioTrackList](#)<sup>p354</sup> object representing the audio tracks available in the [media element](#)<sup>p326</sup>'s [media resource](#)<sup>p328</sup>.

The `videoTracks` attribute of a [media element](#)<sup>p326</sup> must return a [live](#)<sup>p43</sup> [VideoTrackList](#)<sup>p354</sup> object representing the video tracks available in the [media element](#)<sup>p326</sup>'s [media resource](#)<sup>p328</sup>.

**Note** There are only ever one [AudioTrackList](#)<sup>p354</sup> object and one [VideoTrackList](#)<sup>p354</sup> object per [media element](#)<sup>p326</sup>, even if another [media resource](#)<sup>p328</sup> is loaded into the element: the objects are reused. (The [AudioTrack](#)<sup>p354</sup> and [VideoTrack](#)<sup>p354</sup> objects are not, though.)

##### Example

In this example, a script defines a function that takes a URL to a video and a reference to an element where the video is to be placed. That function then tries to load the video, and, once it is loaded, checks to see if there is a sign-language track available. If there is, it also displays that track. Both tracks are just placed in the given container; it's assumed that styles have been applied to make this work in a pretty way!

```
<script>
function loadVideo(url, container) {
 var controller = new MediaController();
 var video = document.createElement('video');
 video.src = url;
 video.autoplay = true;
 video.controls = true;
 video.controller = controller;
 container.appendChild(video);
 video.onloadedmetadata = function (event) {
 for (var i = 0; i < video.videoTracks.length; i += 1) {
 if (video.videoTracks[i].kind == 'sign') {
 var sign = document.createElement('video');
 sign.src = url + '#track=' + video.videoTracks[i].id;
 sign.autoplay = true;
 sign.controller = controller;
 container.appendChild(sign);
 return;
 }
 }
 };
}
</script>
```

#### 4.8.14.10.1 [AudioTrackList](#)<sup>p354</sup> and [VideoTrackList](#)<sup>p354</sup> objects

The [AudioTrackList](#)<sup>p354</sup> and [VideoTrackList](#)<sup>p354</sup> interfaces are used by attributes defined in the previous section.

IDL

```
interface AudioTrackList : EventTarget {
 readonly attribute unsigned long length;
 getter AudioTrack (unsigned long index);
 AudioTrack? getTrackById(DOMString id);

 attribute EventHandler onchange;
 attribute EventHandler onaddtrack;
 attribute EventHandler onremovetrack;
};

interface AudioTrack {
 readonly attribute DOMString id;
 readonly attribute DOMString kind;
 readonly attribute DOMString label;
 readonly attribute DOMString language;
 attribute boolean enabled;
};

interface VideoTrackList : EventTarget {
 readonly attribute unsigned long length;
 getter VideoTrack (unsigned long index);
 VideoTrack? getTrackById(DOMString id);
 readonly attribute long selectedIndex;

 attribute EventHandler onchange;
 attribute EventHandler onaddtrack;
 attribute EventHandler onremovetrack;
};

interface VideoTrack {
 readonly attribute DOMString id;
 readonly attribute DOMString kind;
 readonly attribute DOMString label;
 readonly attribute DOMString language;
 attribute boolean selected;
};
```

Note

`media.audioTracks`<sup>p353</sup>.`length`<sup>p355</sup>

`media.videoTracks`<sup>p353</sup>.`length`<sup>p355</sup>

Returns the number of tracks in the list.

`audioTrack = media.audioTracks`<sup>p353</sup>[`index`]

`videoTrack = media.videoTracks`<sup>p353</sup>[`index`]

Returns the specified [AudioTrack](#)<sup>p354</sup> or [VideoTrack](#)<sup>p354</sup> object.

`audioTrack = media.audioTracks`<sup>p353</sup>.`getTrackById`<sup>p355</sup>(`id`)

`videoTrack = media.videoTracks`<sup>p353</sup>.`getTrackById`<sup>p355</sup>(`id`)

Returns the [AudioTrack](#)<sup>p354</sup> or [VideoTrack](#)<sup>p354</sup> object with the given identifier, or null if no track has that identifier.

`audioTrack . idp356`

`videoTrack . idp356`

Returns the ID of the given track. This is the ID that can be used with a fragment identifier if the format supports the *Media Fragments URI* syntax, and that can be used with the `getTrackById()` method. [MEDIAFRAG]<sup>p151</sup>

`audioTrack . kindp356`

`videoTrack . kindp356`

Returns the category the given track falls into. The [possible track categories<sup>p356</sup>](#) are given below.

`audioTrack . labelp356`

`videoTrack . labelp356`

Returns the label of the given track, if known, or the empty string otherwise.

`audioTrack . languagep356`

`videoTrack . languagep356`

Returns the language of the given track, if known, or the empty string otherwise.

`audioTrack . enabledp357 [= value]`

Returns true if the given track is active, and false otherwise.

Can be set, to change whether the track is enabled or not. If multiple audio tracks are enabled simultaneously, they are mixed.

`media . videoTracksp353 . selectedIndexp357`

Returns the index of the currently selected track, if any, or -1 otherwise.

`videoTrack . selectedp357 [= value]`

Returns true if the given track is active, and false otherwise.

Can be set, to change whether the track is selected or not. Either zero or one video track is selected; selecting a new track while a previous one is selected will unselect the previous one.

An [AudioTrackList<sup>p354</sup>](#) object represents a dynamic list of zero or more audio tracks, of which zero or more can be enabled at a time. Each audio track is represented by an [AudioTrack<sup>p354</sup>](#) object.

A [VideoTrackList<sup>p354</sup>](#) object represents a dynamic list of zero or more video tracks, of which zero or one can be selected at a time. Each video track is represented by a [VideoTrack<sup>p354</sup>](#) object.

Tracks in [AudioTrackList<sup>p354</sup>](#) and [VideoTrackList<sup>p354</sup>](#) objects must be consistently ordered. If the [media resource<sup>p328</sup>](#) is in a format that defines an order, then that order must be used; otherwise, the order must be the relative order in which the tracks are declared in the [media resource<sup>p328</sup>](#). The order used is called the *natural order* of the list.

**Note** *Each track in one of these objects thus has an index; the first has the index 0, and each subsequent track is numbered one higher than the previous one. If a [media resource<sup>p328</sup>](#) dynamically adds or removes audio or video tracks, then the indices of the tracks will change dynamically. If the [media resource<sup>p328</sup>](#) changes entirely, then all the previous tracks will be removed and replaced with new tracks.*

The `AudioTrackList.length` and `VideoTrackList.length` attributes must return the number of tracks represented by their objects at the time of getting.

The [supported property indices<sup>p49</sup>](#) of [AudioTrackList<sup>p354</sup>](#) and [VideoTrackList<sup>p354</sup>](#) objects at any instant are the numbers from zero to the number of tracks represented by the respective object minus one, if any tracks are represented. If an [AudioTrackList<sup>p354</sup>](#) or [VideoTrackList<sup>p354</sup>](#) object represents no tracks, it has no [supported property indices<sup>p49</sup>](#).

To [determine the value of an indexed property<sup>p49</sup>](#) for a given index `index` in an [AudioTrackList<sup>p354</sup>](#) or [VideoTrackList<sup>p354</sup>](#) object `list`, the user agent must return the [AudioTrack<sup>p354</sup>](#) or [VideoTrack<sup>p354</sup>](#) object that represents the `index`th track in `list`.

The `AudioTrackList.getTrackById(id)` and `VideoTrackList.getTrackById(id)` methods must return the first [AudioTrack<sup>p354</sup>](#) or [VideoTrack<sup>p354</sup>](#) object (respectively) in the [AudioTrackList<sup>p354</sup>](#) or [VideoTrackList<sup>p354</sup>](#) object (respectively) whose identifier is equal to the value of the `id` argument (in the natural order of the list, as defined above). When no tracks match the given argument, the methods must return null.

The [AudioTrack](#)<sup>p354</sup> and [VideoTrack](#)<sup>p354</sup> objects represent specific tracks of a [media resource](#)<sup>p328</sup>. Each track can have an identifier, category, label, and language. These aspects of a track are permanent for the lifetime of the track; even if a track is removed from a [media resource](#)<sup>p328</sup>'s [AudioTrackList](#)<sup>p354</sup> or [VideoTrackList](#)<sup>p354</sup> objects, those aspects do not change.

In addition, [AudioTrack](#)<sup>p354</sup> objects can each be enabled or disabled; this is the audio track's *enabled state*. When an [AudioTrack](#)<sup>p354</sup> is created, its *enabled state* must be set to false (disabled). The [resource fetch algorithm](#)<sup>p334</sup> can override this.

Similarly, a single [VideoTrack](#)<sup>p354</sup> object per [VideoTrackList](#)<sup>p354</sup> object can be selected, this is the video track's *selection state*. When a [VideoTrack](#)<sup>p354</sup> is created, its *selection state* must be set to false (not selected). The [resource fetch algorithm](#)<sup>p334</sup> can override this.

The [AudioTrack.id](#) and [VideoTrack.id](#) attributes must return the identifier of the track, if it has one, or the empty string otherwise. If the [media resource](#)<sup>p328</sup> is in a format that supports the *Media Fragments URI* fragment identifier syntax, the identifier returned for a particular track must be the same identifier that would enable the track if used as the name of a track in the track dimension of such a fragment identifier. [\[MEDIAFRAG\]](#)<sup>p1151</sup> [\[INBAND\]](#)<sup>p1150</sup>

**Example** For example, in Ogg files, this would be the Name header field of the track. [\[OGGSKELETONHEADERS\]](#)<sup>p1151</sup>

The [AudioTrack.kind](#) and [VideoTrack.kind](#) attributes must return the category of the track, if it has one, or the empty string otherwise.

The category of a track is the string given in the first column of the table below that is the most appropriate for the track based on the definitions in the table's second and third columns, as determined by the metadata included in the track in the [media resource](#)<sup>p328</sup>. The cell in the third column of a row says what the category given in the cell in the first column of that row applies to; a category is only appropriate for an audio track if it applies to audio tracks, and a category is only appropriate for video tracks if it applies to video tracks. Categories must only be returned for [AudioTrack](#)<sup>p354</sup> objects if they are appropriate for audio, and must only be returned for [VideoTrack](#)<sup>p354</sup> objects if they are appropriate for video.

For Ogg files, the Role header field of the track gives the relevant metadata. For DASH media resources, the [Role](#) element conveys the information. For WebM, only the [FlagDefault](#) element currently maps to a value. The *Sourcing In-band Media Resource Tracks from Media Containers into HTML* specification has further details. [\[OGGSKELETONHEADERS\]](#)<sup>p1151</sup> [\[DASH\]](#)<sup>p1149</sup> [\[WEBMCG\]](#)<sup>p1154</sup> [\[INBAND\]](#)<sup>p1150</sup>

Return values for [AudioTrack.kind](#)<sup>p356</sup> and [VideoTrack.kind](#)<sup>p356</sup>

Category	Definition	Applies to...	Examples
" <a href="#">alternative</a> "	A possible alternative to the main track, e.g. a different take of a song (audio), or a different angle (video).	Audio and video.	Ogg: "audio/alternate" or "video/alternate"; DASH: "alternate" without "main" and "commentary" roles, and, for audio, without the "dub" role (other roles ignored).
" <a href="#">captions</a> "	A version of the main video track with captions burnt in. (For legacy content; new content would use text tracks.)	Video only.	DASH: "caption" and "main" roles together (other roles ignored).
" <a href="#">descriptions</a> "	An audio description of a video track.	Audio only.	Ogg: "audio/audiodesc".
" <a href="#">main</a> "	The primary audio or video track.	Audio and video.	Ogg: "audio/main" or "video/main"; WebM: the "FlagDefault" element is set; DASH: "main" role without "caption", "subtitle", and "dub" roles (other roles ignored).
" <a href="#">main-desc</a> "	The primary audio track, mixed with audio descriptions.	Audio only.	AC3 audio in MPEG-2 TS: bsmod=2 and full_svc=1.
" <a href="#">sign</a> "	A sign-language interpretation of an audio track.	Video only.	Ogg: "video/sign".
" <a href="#">subtitles</a> "	A version of the main video track with subtitles burnt in. (For legacy content; new content would use text tracks.)	Video only.	DASH: "subtitle" and "main" roles together (other roles ignored).
" <a href="#">translation</a> "	A translated version of the main audio track.	Audio only.	Ogg: "audio/dub". DASH: "dub" and "main" roles together (other roles ignored).
" <a href="#">commentary</a> "	Commentary on the primary audio or video track, e.g. a director's commentary.	Audio and video.	DASH: "commentary" role without "main" role (other roles ignored).
"" (empty string)	No explicit kind, or the kind given by the track's metadata is not recognised by the user agent.	Audio and video.	

The [AudioTrack.label](#) and [VideoTrack.label](#) attributes must return the label of the track, if it has one, or the empty string otherwise. [\[INBAND\]](#)<sup>p1150</sup>

The [AudioTrack.language](#) and [VideoTrack.language](#) attributes must return the BCP 47 language tag of the language of the track, if it has one, or the empty string otherwise. If the user agent is not able to express that language as a BCP 47 language tag (for example because the

language information in the [media resource](#)<sup>p328</sup>'s format is a free-form string without a defined interpretation), then the method must return the empty string, as if the track had no language. [[INBAND](#)]<sup>p1150</sup>

The [AudioTrack.enabled](#) attribute, on getting, must return true if the track is currently enabled, and false otherwise. On setting, it must enable the track if the new value is true, and disable it otherwise. (If the track is no longer in an [AudioTrackList](#)<sup>p354</sup> object, then the track being enabled or disabled has no effect beyond changing the value of the attribute on the [AudioTrack](#)<sup>p354</sup> object.)

Whenever an audio track in an [AudioTrackList](#)<sup>p354</sup> that was disabled is enabled, and whenever one that was enabled is disabled, the user agent must [queue a task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> named [change](#)<sup>p387</sup> at the [AudioTrackList](#)<sup>p354</sup> object.

An audio track that has no data for a particular position on the [media timeline](#)<sup>p341</sup>, or that does not exist at that position, must be interpreted as being silent at that point on the timeline.

The [VideoTrackList.selectedIndex](#) attribute must return the index of the currently selected track, if any. If the [VideoTrackList](#)<sup>p354</sup> object does not currently represent any tracks, or if none of the tracks are selected, it must instead return -1.

The [VideoTrack.selected](#) attribute, on getting, must return true if the track is currently selected, and false otherwise. On setting, it must select the track if the new value is true, and unselect it otherwise. If the track is in a [VideoTrackList](#)<sup>p354</sup>, then all the other [VideoTrack](#)<sup>p354</sup> objects in that list must be unselected. (If the track is no longer in a [VideoTrackList](#)<sup>p354</sup> object, then the track being selected or unselected has no effect beyond changing the value of the attribute on the [VideoTrack](#)<sup>p354</sup> object.)

Whenever a track in a [VideoTrackList](#)<sup>p354</sup> that was previously not selected is selected, and whenever the selected track in a [VideoTrackList](#)<sup>p354</sup> is unselected without a new track being selected in its stead, the user agent must [queue a task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> named [change](#)<sup>p387</sup> at the [VideoTrackList](#)<sup>p354</sup> object. This [task](#)<sup>p834</sup> must be [queued](#)<sup>p835</sup> before the [task](#)<sup>p834</sup> that fires the [resize](#)<sup>p387</sup> event, if any.

A video track that has no data for a particular position on the [media timeline](#)<sup>p341</sup> must be interpreted as being fully transparent black at that point on the timeline, with the same dimensions as the last frame before that position, or, if the position is before all the data for that track, the same dimensions as the first frame for that track. A track that does not exist at all at the current position must be treated as if it existed but had no data.

**Example** For instance, if a video has a track that is only introduced after one hour of playback, and the user selects that track then goes back to the start, then the user agent will act as if that track started at the start of the [media resource](#)<sup>p328</sup> but was simply transparent until one hour in.

The following are the [event handlers](#)<sup>p839</sup> (and their corresponding [event handler event types](#)<sup>p839</sup>) that must be supported, as [event handler IDL attributes](#)<sup>p839</sup>, by all objects implementing the [AudioTrackList](#)<sup>p354</sup> and [VideoTrackList](#)<sup>p354</sup> interfaces:

Event handler <sup>p839</sup>	Event handler event type <sup>p839</sup>
<a href="#">onchange</a>	<a href="#">change</a> <sup>p387</sup>
<a href="#">onaddtrack</a>	<a href="#">addtrack</a> <sup>p387</sup>
<a href="#">onremovetrack</a>	<a href="#">removetrack</a> <sup>p387</sup>

#### 4.8.14.10.2 Selecting specific audio and video tracks declaratively

The [audioTracks](#)<sup>p353</sup> and [videoTracks](#)<sup>p353</sup> attributes allow scripts to select which track should play, but it is also possible to select specific tracks declaratively, by specifying particular tracks in the fragment identifier of the [URL](#)<sup>p48</sup> of the [media resource](#)<sup>p328</sup>. The format of the fragment identifier depends on the [MIME type](#)<sup>p42</sup> of the [media resource](#)<sup>p328</sup>. [[RFC2046](#)]<sup>p1152</sup> [[URL](#)]<sup>p1153</sup>

**Example** In this example, a video that uses a format that supports the *Media Fragments URI* fragment identifier syntax is embedded in such a way that the alternative angles labeled "Alternative" are enabled instead of the default video track. [[MEDIAFRAG](#)]<sup>p1151</sup>

```
<video src="myvideo#track=Alternative"></video>
```

#### 4.8.14.11 Synchronising multiple media elements

##### 4.8.14.11.1 Introduction

Each [media element](#)<sup>p326</sup> can have a [MediaController](#)<sup>p358</sup>. A [MediaController](#)<sup>p358</sup> is an object that coordinates the playback of multiple [media elements](#)<sup>p326</sup>, for instance so that a sign-language interpreter track can be overlaid on a video track, with the two being kept synchronised.

By default, a [media element](#)<sup>p326</sup> has no [MediaController](#)<sup>p358</sup>. An implicit [MediaController](#)<sup>p358</sup> can be assigned using the [mediagroup](#)<sup>p364</sup> content attribute. An explicit [MediaController](#)<sup>p358</sup> can be assigned directly using the [controller](#)<sup>p360</sup> IDL attribute.

[Media elements](#)<sup>p326</sup> with a [MediaController](#)<sup>p358</sup> are said to be *slaved* to their controller. The [MediaController](#)<sup>p358</sup> modifies the playback rate and the playback volume of each of the [media elements](#)<sup>p326</sup> slaved to it, and ensures that when any of its slaved [media elements](#)<sup>p326</sup> unexpectedly stall, the others are stopped at the same time.

When a [media element](#)<sup>p326</sup> is slaved to a [MediaController](#)<sup>p358</sup>, its playback rate is fixed to that of the other tracks in the same [MediaController](#)<sup>p358</sup>, and any looping is disabled.

#### 4.8.14.11.2 Media controllers

IDL

```
enum MediaControllerPlaybackState { "waiting", "playing", "ended" };
[Constructor]
interface MediaController : EventTarget {
 readonly attribute unsigned short readyState; // uses HTMLMediaElement.readyState's values

 readonly attribute TimeRanges buffered;

```

**Note**

**controller = new MediaController<sup>p360</sup>()**

Returns a new [MediaController<sup>p358</sup>](#) object.

**media . controller<sup>p360</sup> [= controller]**

Returns the current [MediaController<sup>p358</sup>](#) for the [media element<sup>p326</sup>](#), if any; returns null otherwise.

Can be set, to set an explicit [MediaController<sup>p358</sup>](#). Doing so removes the [mediagroup<sup>p364</sup>](#) attribute, if any.

**controller . readyState<sup>p361</sup>**

Returns the state that the [MediaController<sup>p358</sup>](#) was in the last time it fired events as a result of [reporting the controller state<sup>p363</sup>](#). The values of this attribute are the same as for the [readyState<sup>p345</sup>](#) attribute of [media elements<sup>p326</sup>](#).

**controller . buffered<sup>p361</sup>**

Returns a [TimeRanges<sup>p384</sup>](#) object that represents the intersection of the time ranges for which the user agent has all relevant media data for all the slaved [media elements<sup>p326</sup>](#).

**controller . seekable<sup>p361</sup>**

Returns a [TimeRanges<sup>p384</sup>](#) object that represents the intersection of the time ranges into which the user agent can seek for all the slaved [media elements<sup>p326</sup>](#).

**controller . duration<sup>p361</sup>**

Returns the difference between the earliest playable moment and the latest playable moment (not considering whether the data in question is actually buffered or directly seekable, but not including time in the future for infinite streams). Will return zero if there is no media.

**controller . currentTime<sup>p361</sup> [= value ]**

Returns the [current playback position<sup>p342</sup>](#), in seconds, as a position between zero time and the current [duration<sup>p361</sup>](#).

Can be set, to seek to the given time.

**controller . paused<sup>p361</sup>**

Returns true if playback is paused; false otherwise. When this attribute is true, any [media element<sup>p326</sup>](#) slaved to this controller will be stopped.

**controller . playbackState<sup>p361</sup>**

Returns the state that the [MediaController<sup>p358</sup>](#) was in the last time it fired events as a result of [reporting the controller state<sup>p363</sup>](#). The value of this attribute is either "[playing<sup>p364</sup>](#)", indicating that the media is actively playing, "[ended<sup>p364</sup>](#)", indicating that the media is not playing because playback has reached the end of all the [slaved media elements<sup>p360</sup>](#), or "[waiting<sup>p364</sup>](#)", indicating that the media is not playing for some other reason (e.g. the [MediaController<sup>p358</sup>](#) is paused).

**controller . pause<sup>p361</sup>()**

Sets the [paused<sup>p361</sup>](#) attribute to true.

**controller . unpause<sup>p361</sup>()**

Sets the [paused<sup>p361</sup>](#) attribute to false.

**controller . play<sup>p361</sup>()**

Sets the [paused<sup>p361</sup>](#) attribute to false and invokes the [play\(\)<sup>p347</sup>](#) method of each [slaved media element<sup>p360</sup>](#).

**controller . played<sup>p361</sup>**

Returns a [TimeRanges<sup>p384</sup>](#) object that represents the union of the time ranges in all the slaved [media elements<sup>p326</sup>](#) that have been played.

**controller . defaultPlaybackRate<sup>p361</sup> [= value ]**

Returns the default rate of playback.

Can be set, to change the default rate of playback.

This default rate has no direct effect on playback, but if the user switches to a fast-forward mode, when they return to the normal playback mode, it is expected that rate of playback ([playbackRate<sup>p361</sup>](#)) will be returned to this default rate.

**controller . playbackRate<sup>p361</sup> [ = value ]**

Returns the current rate of playback.

Can be set, to change the rate of playback.

**controller . volume<sup>p362</sup> [ = value ]**

Returns the current playback volume multiplier, as a number in the range 0.0 to 1.0, where 0.0 is the quietest and 1.0 the loudest.

Can be set, to change the volume multiplier.

Throws an [IndexSizeError<sup>p50</sup>](#) exception if the new value is not in the range 0.0 .. 1.0.

**controller . muted<sup>p362</sup> [ = value ]**

Returns true if all audio is muted (regardless of other attributes either on the controller or on any [media elements<sup>p326</sup>](#) slaved to this controller), and false otherwise.

Can be set, to change whether the audio is muted or not.

A [media element<sup>p326</sup>](#) can have a **current media controller**, which is a [MediaController<sup>p358</sup>](#) object. When a [media element<sup>p326</sup>](#) is created without a [mediagroup<sup>p364</sup>](#) attribute, it does not have a [current media controller<sup>p360</sup>](#). (If it is created *with* such an attribute, then that attribute initialises the [current media controller<sup>p360</sup>](#), as defined below.)

The **slaved media elements** of a [MediaController<sup>p358</sup>](#) are the [media elements<sup>p326</sup>](#) whose [current media controller<sup>p360</sup>](#) is that [MediaController<sup>p358</sup>](#). All the [slaved media elements<sup>p360</sup>](#) of a [MediaController<sup>p358</sup>](#) must use the same clock for their definition of their [media timeline<sup>p341</sup>](#)'s unit time. When the user agent is required to act on each [slaved media element<sup>p360</sup>](#) in turn, they must be processed in the order that they were last associated with the [MediaController<sup>p358</sup>](#).

The **controller** attribute on a [media element<sup>p326</sup>](#), on getting, must return the element's [current media controller<sup>p360</sup>](#), if any, or null otherwise. On setting, the user agent must run the following steps:

1. Let *m* be the [media element<sup>p326</sup>](#) in question.
2. Let *old controller* be *m*'s [current media controller<sup>p360</sup>](#), if it currently has one, and null otherwise.
3. Let *new controller* be null.
4. Let *m* have no [current media controller<sup>p360</sup>](#), if it currently has one.
5. Remove the element's [mediagroup<sup>p364</sup>](#) content attribute, if any.
6. If the new value is null, then jump to the *update controllers* step below.
7. Let *m*'s [current media controller<sup>p360</sup>](#) be the new value.
8. Let *new controller* be *m*'s [current media controller<sup>p360</sup>](#).
9. [Bring the media element up to speed with its new media controller<sup>p362</sup>](#).
10. *Update controllers*: If *old controller* and *new controller* are the same (whether both null or both the same controller) then abort these steps.
  11. If *old controller* is not null and still has one or more [slaved media elements<sup>p360</sup>](#), then [report the controller state<sup>p363</sup>](#) for *old controller*.
  12. If *new controller* is not null, then [report the controller state<sup>p363</sup>](#) for *new controller*.

The [MediaController\(\)](#) constructor, when invoked, must return a newly created [MediaController<sup>p358</sup>](#) object.

The `readyState` attribute must return the value to which it was most recently set. When the `MediaController`<sup>p358</sup> object is created, the attribute must be set to the value 0 (`HAVE NOTHING`<sup>p343</sup>). The value is updated by the `report the controller state`<sup>p363</sup> algorithm below.

The `seekable` attribute must return a new static `normalised TimeRanges object`<sup>p385</sup> that represents the intersection of the ranges of the `media resources`<sup>p328</sup> of the `slaved media elements`<sup>p360</sup> that the user agent is able to seek to, at the time the attribute is evaluated.

The `buffered` attribute must return a new static `normalised TimeRanges object`<sup>p385</sup> that represents the intersection of the ranges of the `media resources`<sup>p328</sup> of the `slaved media elements`<sup>p360</sup> that the user agent has buffered, at the time the attribute is evaluated. User agents must accurately determine the ranges available, even for media streams where this can only be determined by tedious inspection.

The `duration` attribute must return the `media controller duration`<sup>p362</sup>.

Every 15 to 250ms, or whenever the `MediaController`<sup>p358</sup>'s `media controller duration`<sup>p362</sup> changes, whichever happens least often, the user agent must `queue a task`<sup>p835</sup> to `fire a simple event`<sup>p846</sup> named `durationchange`<sup>p387</sup> at the `MediaController`<sup>p358</sup>. If the `MediaController`<sup>p358</sup>'s `media controller duration`<sup>p362</sup> decreases such that the `media controller position`<sup>p362</sup> is greater than the `media controller duration`<sup>p362</sup>, the user agent must `immediately`<sup>p41</sup> `seek the media controller`<sup>p362</sup> to `media controller duration`<sup>p362</sup>.

The `currentTime` attribute must return the `media controller position`<sup>p362</sup> on getting, and on setting must `seek the media controller`<sup>p362</sup> to the new value.

Every 15 to 250ms, or whenever the `MediaController`<sup>p358</sup>'s `media controller position`<sup>p362</sup> changes, whichever happens least often, the user agent must `queue a task`<sup>p835</sup> to `fire a simple event`<sup>p846</sup> named `timeupdate`<sup>p387</sup> at the `MediaController`<sup>p358</sup>.

When a `MediaController`<sup>p358</sup> is created it is a **playing media controller**. It can be changed into a **paused media controller** and back either via the user agent's user interface (when the element is `exposing a user interface to the user`<sup>p382</sup>) or by script using the APIs defined in this section (see below).

The `paused` attribute must return true if the `MediaController`<sup>p358</sup> object is a **paused media controller**<sup>p361</sup>, and false otherwise.

When the `pause ()` method is invoked, if the `MediaController`<sup>p358</sup> is a **playing media controller**<sup>p361</sup> then the user agent must change the `MediaController`<sup>p358</sup> into a **paused media controller**<sup>p361</sup>, `queue a task`<sup>p835</sup> to `fire a simple event`<sup>p846</sup> named `pause`<sup>p387</sup> at the `MediaController`<sup>p358</sup>, and then `report the controller state`<sup>p363</sup> of the `MediaController`<sup>p358</sup>.

When the `unpause ()` method is invoked, if the `MediaController`<sup>p358</sup> is a **paused media controller**<sup>p361</sup>, the user agent must change the `MediaController`<sup>p358</sup> into a **playing media controller**<sup>p361</sup>, `queue a task`<sup>p835</sup> to `fire a simple event`<sup>p846</sup> named `play`<sup>p387</sup> at the `MediaController`<sup>p358</sup>, and then `report the controller state`<sup>p363</sup> of the `MediaController`<sup>p358</sup>.

When the `play ()` method is invoked, the user agent must invoke the `play ()`<sup>p347</sup> method of each `slaved media element`<sup>p360</sup> in turn, and then invoke the `unpause`<sup>p361</sup> method of the `MediaController`<sup>p358</sup>.

The `playbackState` attribute must return the value to which it was most recently set. When the `MediaController`<sup>p358</sup> object is created, the attribute must be set to the value "`waiting`<sup>p344</sup>". The value is updated by the `report the controller state`<sup>p363</sup> algorithm below.

The `played` attribute must return a new static `normalised TimeRanges object`<sup>p385</sup> that represents the union of the ranges of points on the `media timelines`<sup>p341</sup> of the `media resources`<sup>p328</sup> of the `slaved media elements`<sup>p360</sup> that the user agent has so far reached through the usual monotonic increase of their `current playback positions`<sup>p342</sup> during normal playback, at the time the attribute is evaluated.

A `MediaController`<sup>p358</sup> has a **media controller default playback rate** and a **media controller playback rate**, which must both be set to 1.0 when the `MediaController`<sup>p358</sup> object is created.

The `defaultPlaybackRate` attribute, on getting, must return the `MediaController`<sup>p358</sup>'s `media controller default playback rate`<sup>p361</sup>, and on setting, must set the `MediaController`<sup>p358</sup>'s `media controller default playback rate`<sup>p361</sup> to the new value, then `queue a task`<sup>p835</sup> to `fire a simple event`<sup>p846</sup> named `ratechange`<sup>p387</sup> at the `MediaController`<sup>p358</sup>.

The `playbackRate` attribute, on getting, must return the `MediaController`<sup>p358</sup>'s `media controller playback rate`<sup>p361</sup>, and on setting, must set the `MediaController`<sup>p358</sup>'s `media controller playback rate`<sup>p361</sup> to the new value, then `queue a task`<sup>p835</sup> to `fire a simple event`<sup>p846</sup> named `ratechange`<sup>p387</sup> at the `MediaController`<sup>p358</sup>.

A [MediaController](#)<sup>p358</sup> has a **media controller volume multiplier**, which must be set to 1.0 when the [MediaController](#)<sup>p358</sup> object is created, and a **media controller mute override**, much must initially be false.

The **volume** attribute, on getting, must return the [MediaController](#)<sup>p358</sup>'s [media controller volume multiplier](#)<sup>p362</sup>, and on setting, if the new value is in the range 0.0 to 1.0 inclusive, must set the [MediaController](#)<sup>p358</sup>'s [media controller volume multiplier](#)<sup>p362</sup> to the new value and [queue a task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> named [volumechange](#)<sup>p387</sup> at the [MediaController](#)<sup>p358</sup>. If the new value is outside the range 0.0 to 1.0 inclusive, then, on setting, an [IndexSizeError](#)<sup>p50</sup> exception must be thrown instead.

The **muted** attribute, on getting, must return the [MediaController](#)<sup>p358</sup>'s [media controller mute override](#)<sup>p362</sup>, and on setting, must set the [MediaController](#)<sup>p358</sup>'s [media controller mute override](#)<sup>p362</sup> to the new value and [queue a task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> named [volumechange](#)<sup>p387</sup> at the [MediaController](#)<sup>p358</sup>.

The [media resources](#)<sup>p328</sup> of all the [slaved media elements](#)<sup>p360</sup> of a [MediaController](#)<sup>p358</sup> have a defined temporal relationship which provides relative offsets between the zero time of each such [media resource](#)<sup>p328</sup>: for [media resources](#)<sup>p328</sup> with a [timeline offset](#)<sup>p343</sup>, their relative offsets are the difference between their [timeline offset](#)<sup>p343</sup>; the zero times of all the [media resources](#)<sup>p328</sup> without a [timeline offset](#)<sup>p343</sup> are not offset from each other (i.e. the origins of their timelines are cotemporal); and finally, the zero time of the [media resource](#)<sup>p328</sup> with the earliest [timeline offset](#)<sup>p343</sup> (if any) is not offset from the zero times of the [media resources](#)<sup>p328</sup> without a [timeline offset](#)<sup>p343</sup> (i.e. the origins of [media resources](#)<sup>p328</sup> without a [timeline offset](#)<sup>p343</sup> are further cotemporal with the earliest defined point on the timeline of the [media resource](#)<sup>p328</sup> with the earliest [timeline offset](#)<sup>p343</sup>).

The **media resource end position** of a [media resource](#)<sup>p328</sup> in a [media element](#)<sup>p326</sup> is defined as follows: if the [media resource](#)<sup>p328</sup> has a finite and known duration, the [media resource end position](#)<sup>p362</sup> is the duration of the [media resource](#)<sup>p328</sup>'s timeline (the last defined position on that timeline); otherwise, the [media resource](#)<sup>p328</sup>'s duration is infinite or unknown, and the [media resource end position](#)<sup>p362</sup> is the time of the last frame of [media data](#)<sup>p328</sup> currently available for that [media resource](#)<sup>p328</sup>.

Each [MediaController](#)<sup>p358</sup> also has its own defined timeline. On this timeline, all the [media resources](#)<sup>p328</sup> of all the [slaved media elements](#)<sup>p360</sup> of the [MediaController](#)<sup>p358</sup> are temporally aligned according to their defined offsets. The **media controller duration** of that [MediaController](#)<sup>p358</sup> is the time from the earliest [earliest possible position](#)<sup>p342</sup>, relative to this [MediaController](#)<sup>p358</sup> timeline, of any of the [media resources](#)<sup>p328</sup> of the [slaved media elements](#)<sup>p360</sup> of the [MediaController](#)<sup>p358</sup>, to the time of the latest [media resource end position](#)<sup>p362</sup> of the [media resources](#)<sup>p328</sup> of the [slaved media elements](#)<sup>p360</sup> of the [MediaController](#)<sup>p358</sup>, again relative to this [MediaController](#)<sup>p358</sup> timeline.

Each [MediaController](#)<sup>p358</sup> has a **media controller position**. This is the time on the [MediaController](#)<sup>p358</sup>'s timeline at which the user agent is trying to play the [slaved media elements](#)<sup>p360</sup>. When a [MediaController](#)<sup>p358</sup> is created, its [media controller position](#)<sup>p362</sup> is initially zero.

When the user agent is to **bring a media element up to speed with its new media controller**, it must [seek](#)<sup>p351</sup> that [media element](#)<sup>p326</sup> to the [MediaController](#)<sup>p358</sup>'s [media controller position](#)<sup>p362</sup> relative to the [media element](#)<sup>p326</sup>'s timeline.

When the user agent is to **seek the media controller** to a particular *new playback position*, it must follow these steps:

1. If the *new playback position* is less than zero, then set it to zero.
2. If the *new playback position* is greater than the [media controller duration](#)<sup>p362</sup>, then set it to the [media controller duration](#)<sup>p362</sup>.
3. Set the [media controller position](#)<sup>p362</sup> to the *new playback position*.
4. [Seek](#)<sup>p351</sup> each [slaved media element](#)<sup>p360</sup> to the *new playback position* relative to the [media element](#)<sup>p326</sup> timeline.

A [MediaController](#)<sup>p358</sup> is a **restrained media controller** if the [MediaController](#)<sup>p358</sup> is a [playing media controller](#)<sup>p361</sup>, but either at least one of its [slaved media elements](#)<sup>p360</sup> whose [autoplaying flag](#)<sup>p331</sup> is true still has its [paused](#)<sup>p346</sup> attribute set to true, or, all of its [slaved media elements](#)<sup>p360</sup> have their [paused](#)<sup>p346</sup> attribute set to true.

A [MediaController](#)<sup>p358</sup> is a **blocked media controller** if the [MediaController](#)<sup>p358</sup> is a [paused media controller](#)<sup>p361</sup>, or if any of its [slaved media elements](#)<sup>p360</sup> are [blocked media elements](#)<sup>p346</sup>, or if any of its [slaved media elements](#)<sup>p360</sup> whose [autoplaying flag](#)<sup>p331</sup> is true still have their [paused](#)<sup>p346</sup> attribute set to true, or if all of its [slaved media elements](#)<sup>p360</sup> have their [paused](#)<sup>p346</sup> attribute set to true.

A [media element](#)<sup>p326</sup> is **blocked on its media controller** if the [MediaController](#)<sup>p358</sup> is a [blocked media controller](#)<sup>p362</sup>, or if its [media controller position](#)<sup>p362</sup> is either before the [media resource](#)<sup>p328</sup>'s [earliest possible position](#)<sup>p342</sup> relative to the [MediaController](#)<sup>p358</sup>'s timeline or after the end of the [media resource](#)<sup>p328</sup> relative to the [MediaController](#)<sup>p358</sup>'s timeline.

When a [MediaController](#)<sup>p358</sup> is not a [blocked media controller](#)<sup>p362</sup> and it has at least one [slaved media element](#)<sup>p360</sup> whose [Document](#)<sup>p102</sup> is a [fully active](#)<sup>p763</sup> [Document](#)<sup>p102</sup>, the [MediaController](#)<sup>p358</sup>'s [media controller position](#)<sup>p362</sup> must increase monotonically at [media controller playback rate](#)<sup>p361</sup> units of time on the [MediaController](#)<sup>p358</sup>'s timeline per unit time of the clock used by its [slaved media elements](#)<sup>p360</sup>.

When the zero point on the timeline of a [MediaController](#)<sup>p358</sup> moves relative to the timelines of the [slaved media elements](#)<sup>p360</sup> by a time difference  $\Delta T$ , the [MediaController](#)<sup>p358</sup>'s [media controller position](#)<sup>p362</sup> must be decremented by  $\Delta T$ .

**Note** *In some situations, e.g. when playing back a live stream without buffering anything, the [media controller position](#)<sup>p362</sup> would increase monotonically as described above at the same rate as the  $\Delta T$  described in the previous paragraph decreases it, with the end result that for all intents and purposes, the [media controller position](#)<sup>p362</sup> would appear to remain constant (probably with the value 0).*

A [MediaController](#)<sup>p358</sup> has a **most recently reported readiness state**, which is a number from 0 to 4 derived from the numbers used for the [media element](#)<sup>p326</sup> [readyState](#)<sup>p345</sup> attribute, and a **most recently reported playback state**, which is either *playing*, *waiting*, or *ended*.

When a [MediaController](#)<sup>p358</sup> is created, its [most recently reported readiness state](#)<sup>p363</sup> must be set to 0, and its [most recently reported playback state](#)<sup>p363</sup> must be set to *waiting*.

When a user agent is required to **report the controller state** for a [MediaController](#)<sup>p358</sup>, the user agent must run the following steps:

1. If the [MediaController](#)<sup>p358</sup> has no [slaved media elements](#)<sup>p360</sup>, let *new readiness state* be 0.  
Otherwise, let it have the lowest value of the [readyState](#)<sup>p345</sup> IDL attributes of all of its [slaved media elements](#)<sup>p360</sup>.
2. If the [MediaController](#)<sup>p358</sup>'s [most recently reported readiness state](#)<sup>p363</sup> is less than the *new readiness state*, then run these substeps:
  1. Let *next state* be the [MediaController](#)<sup>p358</sup>'s [most recently reported readiness state](#)<sup>p363</sup>.
  2. *Loop*: Increment *next state* by one.
  3. [Queue a task](#)<sup>p835</sup> to run the following steps:
    1. Set the [MediaController](#)<sup>p358</sup>'s [readyState](#)<sup>p361</sup> attribute to the value *next state*.
    2. [Fire a simple event](#)<sup>p846</sup> at the [MediaController](#)<sup>p358</sup> object, whose name is the event name corresponding to the value of *next state* given in the table below.
  4. If *next state* is less than *new readiness state*, then return to the step labeled *loop*.

Otherwise, if the [MediaController](#)<sup>p358</sup>'s [most recently reported readiness state](#)<sup>p363</sup> is greater than *new readiness state* then [queue a task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> at the [MediaController](#)<sup>p358</sup> object, whose name is the event name corresponding to the value of *new readiness state* given in the table below.

Value of <i>new readiness state</i>	Event name
0	<a href="#">emptied</a> <sup>p387</sup>
1	<a href="#">loadedmetadata</a> <sup>p387</sup>
2	<a href="#">loadeddata</a> <sup>p387</sup>
3	<a href="#">canplay</a> <sup>p387</sup>
4	<a href="#">canplaythrough</a> <sup>p387</sup>

3. Let the [MediaController](#)<sup>p358</sup>'s [most recently reported readiness state](#)<sup>p363</sup> be *new readiness state*.
4. Initialise *new playback state* by setting it to the state given for the first matching condition from the following list:
  - ↪ If the [MediaController](#)<sup>p358</sup> has no [slaved media elements](#)<sup>p360</sup>  
Let *new playback state* be *waiting*.
  - ↪ If all of the [MediaController](#)<sup>p358</sup>'s [slaved media elements](#)<sup>p360</sup> have [ended playback](#)<sup>p346</sup> and the [media controller playback rate](#)<sup>p361</sup> is positive or zero  
Let *new playback state* be *ended*.
  - ↪ If the [MediaController](#)<sup>p358</sup> is a [blocked media controller](#)<sup>p362</sup>  
Let *new playback state* be *waiting*.

↪ **Otherwise**

Let new playback state be *playing*.

5. If the *MediaController*<sup>p358</sup>'s *most recently reported playback state*<sup>p363</sup> is not equal to *new playback state* and the *new playback state* is *ended*, then *queue a task*<sup>p835</sup> that, if the *MediaController*<sup>p358</sup> object is a *playing media controller*<sup>p361</sup>, and all of the *MediaController*<sup>p358</sup>'s *slaved media elements*<sup>p360</sup> have still *ended playback*<sup>p346</sup>, and the *media controller playback rate*<sup>p361</sup> is still positive or zero, changes the *MediaController*<sup>p358</sup> object to a *paused media controller*<sup>p361</sup> and then *fires a simple event*<sup>p846</sup> named *pause*<sup>p387</sup> at the *MediaController*<sup>p358</sup> object.
6. If the *MediaController*<sup>p358</sup>'s *most recently reported playback state*<sup>p363</sup> is not equal to *new playback state* then *queue a task*<sup>p835</sup> to run the following steps:
  1. Set the *MediaController*<sup>p358</sup>'s *playbackState*<sup>p361</sup> attribute to the value given in the second column of the row of the following table whose first column contains the *new playback state*.
  2. *Fire a simple event*<sup>p846</sup> at the *MediaController*<sup>p358</sup> object, whose name is the value given in the third column of the row of the following table whose first column contains the *new playback state*.

New playback state	New value for <i>playbackState</i> <sup>p361</sup>	Event name
<i>playing</i>	" <i>playing</i> "	<i>playing</i> <sup>p387</sup>
<i>waiting</i>	" <i>waiting</i> "	<i>waiting</i> <sup>p387</sup>
<i>ended</i>	" <i>ended</i> "	<i>ended</i> <sup>p387</sup>

7. Let the *MediaController*<sup>p358</sup>'s *most recently reported playback state*<sup>p363</sup> be *new playback state*.

The following are the *event handlers*<sup>p839</sup> (and their corresponding *event handler event types*<sup>p839</sup>) that must be supported, as *event handler IDL attributes*<sup>p839</sup>, by all objects implementing the *MediaController*<sup>p358</sup> interface:

Event handler <sup>p839</sup>	Event handler event type <sup>p839</sup>
<i>onemptied</i>	<i>emptied</i> <sup>p387</sup>
<i>onloadedmetadata</i>	<i>loadedmetadata</i> <sup>p387</sup>
<i>onloadeddata</i>	<i>loadeddata</i> <sup>p387</sup>
<i>oncanplay</i>	<i>canplay</i> <sup>p387</sup>
<i>oncanplaythrough</i>	<i>canplaythrough</i> <sup>p387</sup>
<i>onplaying</i>	<i>playing</i> <sup>p387</sup>
<i>onended</i>	<i>ended</i> <sup>p387</sup>
<i>onwaiting</i>	<i>waiting</i> <sup>p387</sup>
<i>ondurationchange</i>	<i>durationchange</i> <sup>p387</sup>
<i>ontimeupdate</i>	<i>timeupdate</i> <sup>p387</sup>
<i>onplay</i>	<i>play</i> <sup>p387</sup>
<i>onpause</i>	<i>pause</i> <sup>p387</sup>
<i>onratechange</i>	<i>ratechange</i> <sup>p387</sup>
<i>onvolumechange</i>	<i>volumechange</i> <sup>p387</sup>

The *task source*<sup>p835</sup> for the *tasks*<sup>p834</sup> listed in this section is the *DOM manipulation task source*<sup>p838</sup>.

#### 4.8.14.11.3 Assigning a media controller declaratively

The *mediagroup* content attribute on *media elements*<sup>p326</sup> can be used to link multiple *media elements*<sup>p326</sup> together by implicitly creating a *MediaController*<sup>p358</sup>. The value is text; *media elements*<sup>p326</sup> with the same value are automatically linked by the user agent.

When a *media element*<sup>p326</sup> is created with a *mediagroup*<sup>p364</sup> attribute, and when a *media element*<sup>p326</sup>'s *mediagroup*<sup>p364</sup> attribute is set, changed, or removed, the user agent must run the following steps:

1. Let *m* be the *media element*<sup>p326</sup> in question.

2. Let *old controller* be *m*'s [current media controller](#)<sup>p360</sup>, if it currently has one, and null otherwise.
  3. Let *new controller* be null.
  4. Let *m* have no [current media controller](#)<sup>p360</sup>, if it currently has one.
  5. If *m*'s [mediagroup](#)<sup>p364</sup> attribute is being removed, then jump to the *update controllers* step below.
  6. If there is another [media element](#)<sup>p326</sup> whose [Document](#)<sup>p102</sup> is the same as *m*'s [node document](#) (even if one or both of these elements are not actually [in the Document](#)<sup>p42</sup>), and which also has a [mediagroup](#)<sup>p364</sup> attribute, and whose [mediagroup](#)<sup>p364</sup> attribute has the same value as the new value of *m*'s [mediagroup](#)<sup>p364</sup> attribute, then let *controller* be that [media element](#)<sup>p326</sup>'s [current media controller](#)<sup>p360</sup>.
- Otherwise, let *controller* be a newly created [MediaController](#)<sup>p358</sup>.
7. Let *m*'s [current media controller](#)<sup>p360</sup> be *controller*.
  8. Let *new controller* be *m*'s [current media controller](#)<sup>p360</sup>.
  9. [Bring the media element up to speed with its new media controller](#)<sup>p362</sup>.
  10. *Update controllers*: If *old controller* and *new controller* are the same (whether both null or both the same controller) then abort these steps.
  11. If *old controller* is not null and still has one or more [slaved media elements](#)<sup>p360</sup>, then [report the controller state](#)<sup>p363</sup> for *old controller*.
  12. If *new controller* is not null, then [report the controller state](#)<sup>p363</sup> for *new controller*.

The [mediaGroup](#) IDL attribute on [media elements](#)<sup>p326</sup> must [reflect](#)<sup>p88</sup> the [mediagroup](#)<sup>p364</sup> content attribute.

#### Example

Multiple [media elements](#)<sup>p326</sup> referencing the same [media resource](#)<sup>p328</sup> will share a single network request. This can be used to efficiently play two (video) tracks from the same [media resource](#)<sup>p328</sup> in two different places on the screen. Used with the [mediagroup](#)<sup>p364</sup> attribute, these elements can also be kept synchronised.

In this example, a sign-language interpreter track from a movie file is overlaid on the primary video track of that same video file using two [video](#)<sup>p317</sup> elements, some CSS, and an implicit [MediaController](#)<sup>p358</sup>:

```
<article>
 <style scoped>
 div { margin: 1em auto; position: relative; width: 400px; height: 300px; }
 video { position: absolute; bottom: 0; right: 0; }
 video:first-child { width: 100%; height: 100%; }
 video:last-child { width: 30%; }
 </style>
 <div>
 <video src="movie.vid#track=Video&track=English" autoplay controls
mediagroup=movie></video>
 <video src="movie.vid#track=sign" autoplay mediagroup=movie></video>
 </div>
</article>
```

#### 4.8.14.12 Timed text tracks

Spec bugs: [18029](#)

##### 4.8.14.12.1 Text track model

A [media element](#)<sup>p326</sup> can have a group of associated [text tracks](#), known as the [media element](#)<sup>p326</sup>'s [list of text tracks](#). The [text tracks](#)<sup>p365</sup> are sorted as follows:

1. The [text tracks](#)<sup>p365</sup> corresponding to [track](#)<sup>p324</sup> element children of the [media element](#)<sup>p326</sup>, in [tree order](#)<sup>p42</sup>.
2. Any [text tracks](#)<sup>p365</sup> added using the [addTextTrack\(\)](#)<sup>p375</sup> method, in the order they were added, oldest first.
3. Any [media-resource-specific text tracks](#)<sup>p369</sup> ([text tracks](#)<sup>p365</sup> corresponding to data in the [media resource](#)<sup>p328</sup>), in the order defined by the [media resource](#)<sup>p328</sup>'s format specification.

A [text track](#)<sup>p365</sup> consists of:

#### The kind of text track

This decides how the track is handled by the user agent. The kind is represented by a string. The possible strings are:

- `subtitles`
- `captions`
- `descriptions`
- `chapters`
- `metadata`

The [kind of track](#)<sup>p366</sup> can change dynamically, in the case of a [text track](#)<sup>p365</sup> corresponding to a [track](#)<sup>p324</sup> element.

#### A label

This is a human-readable string intended to identify the track for the user.

The [label of a track](#)<sup>p366</sup> can change dynamically, in the case of a [text track](#)<sup>p365</sup> corresponding to a [track](#)<sup>p324</sup> element.

When a [text track label](#)<sup>p366</sup> is the empty string, the user agent should automatically generate an appropriate label from the text track's other properties (e.g. the kind of text track and the text track's language) for use in its user interface. This automatically-generated label is not exposed in the API.

#### An in-band metadata track dispatch type

This is a string extracted from the [media resource](#)<sup>p328</sup> specifically for in-band metadata tracks to enable such tracks to be dispatched to different scripts in the document.

**Example** For example, a traditional TV station broadcast streamed on the Web and augmented with Web-specific interactive features could include text tracks with metadata for ad targeting, trivia game data during game shows, player states during sports games, recipe information during food programs, and so forth. As each program starts and ends, new tracks might be added or removed from the stream, and as each one is added, the user agent could bind them to dedicated script modules using the value of this attribute.

Other than for in-band metadata text tracks, the [in-band metadata track dispatch type](#)<sup>p366</sup> is the empty string. How this value is populated for different media formats is described in [steps to expose a media-resource-specific text track](#)<sup>p369</sup>.

#### A language

This is a string (a BCP 47 language tag) representing the language of the text track's cues. [\[BCP47\]](#)<sup>p1148</sup>

The [language of a text track](#)<sup>p366</sup> can change dynamically, in the case of a [text track](#)<sup>p365</sup> corresponding to a [track](#)<sup>p324</sup> element.

#### A readiness state

One of the following:

##### Not loaded

Indicates that the text track's cues have not been obtained.

##### Loading

Indicates that the text track is loading and there have been no fatal errors encountered so far. Further cues might still be added to the track by the parser.

##### Loaded

Indicates that the text track has been loaded with no fatal errors.

##### Failed to load

Indicates that the text track was enabled, but when the user agent attempted to obtain it, this failed in some way (e.g. [URL](#)<sup>p48</sup> could not be [resolved](#)<sup>p82</sup>, network error, unknown text track format). Some or all of the cues are likely missing and will not be obtained.

The [readiness state](#)<sup>p366</sup> of a [text track](#)<sup>p365</sup> changes dynamically as the track is obtained.

#### A mode

One of the following:

### **Disabled**

Indicates that the text track is not active. Other than for the purposes of exposing the track in the DOM, the user agent is ignoring the text track. No cues are active, no events are fired, and the user agent will not attempt to obtain the track's cues.

### **Hidden**

Indicates that the text track is active, but that the user agent is not actively displaying the cues. If no attempt has yet been made to obtain the track's cues, the user agent will perform such an attempt momentarily. The user agent is maintaining a list of which cues are active, and events are being fired accordingly.

### **Showing**

Indicates that the text track is active. If no attempt has yet been made to obtain the track's cues, the user agent will perform such an attempt momentarily. The user agent is maintaining a list of which cues are active, and events are being fired accordingly. In addition, for text tracks whose [kind](#) is [subtitles](#) or [captions](#), the cues are being overlaid on the video as appropriate; for text tracks whose [kind](#) is [descriptions](#), the user agent is making the cues available to the user in a non-visual fashion; and for text tracks whose [kind](#) is [chapters](#), the user agent is making available to the user a mechanism by which the user can navigate to any point in the [media resource](#) by selecting a cue.

### **A list of zero or more cues**

A list of [text track cues](#), along with [rules for updating the text track rendering](#). For example, for WebVTT, the [rules for updating the display of WebVTT text tracks](#). [WEBVTT]<sup>p1154</sup>

The [list of cues of a text track](#) can change dynamically, either because the [text track](#) has [not yet been loaded](#) or is still [loading](#), or due to DOM manipulation.

Each [text track](#) has a corresponding [TextTrack](#) object.

Each [media element](#) has a [list of pending text tracks](#), which must initially be empty, a **blocked-on-parser** flag, which must initially be false, and a **did-perform-automatic-track-selection** flag, which must also initially be false.

When the user agent is required to [populate the list of pending text tracks](#) of a [media element](#), the user agent must add to the element's [list of pending text tracks](#) each [text track](#) in the element's [list of text tracks](#) whose [text track mode](#) is not [disabled](#) and whose [text track readiness state](#) is [loading](#).

Whenever a [track](#) element's parent node changes, the user agent must remove the corresponding [text track](#) from any [list of pending text tracks](#) that it is in.

Whenever a [text track](#)'s [text track readiness state](#) changes to either [loaded](#) or [failed to load](#), the user agent must remove it from any [list of pending text tracks](#) that it is in.

When a [media element](#) is created by an [HTML parser](#) or [XML parser](#), the user agent must set the element's [blocked-on-parser](#) flag to true. When a [media element](#) is popped off the [stack of open elements](#) of an [HTML parser](#) or [XML parser](#), the user agent must [honor user preferences for automatic text track selection](#), [populate the list of pending text tracks](#), and set the element's [blocked-on-parser](#) flag to false.

The [text tracks](#) of a [media element](#) are **ready** when both the element's [list of pending text tracks](#) is empty and the element's [blocked-on-parser](#) flag is false.

Each [media element](#) has a **pending text track change notification flag**, which must initially be unset.

Whenever a [text track](#) that is in a [media element](#)'s [list of text tracks](#) has its [text track mode](#) change value, the user agent must run the following steps for the [media element](#):

1. If the [media element](#)'s [pending text track change notification flag](#) is set, abort these steps.
2. Set the [media element](#)'s [pending text track change notification flag](#).
3. [Queue a task](#) that runs the following substeps:
  1. Unset the [media element](#)'s [pending text track change notification flag](#).
  2. [Fire a simple event](#) named [change](#) at the [media element](#)'s [textTracks](#) attribute's [TextTrackList](#) object.

4. If the [media element](#)<sup>p326</sup>'s [show poster flag](#)<sup>p342</sup> is not set, run the [time marches on](#)<sup>p349</sup> steps.

The [task source](#)<sup>p835</sup> for the [tasks](#)<sup>p834</sup> listed in this section is the [DOM manipulation task source](#)<sup>p838</sup>.

A **text track cue** is the unit of time-sensitive data in a [text track](#)<sup>p365</sup>, corresponding for instance for subtitles and captions to the text that appears at a particular time and disappears at another time.

Each [text track cue](#)<sup>p368</sup> consists of:

#### An identifier

An arbitrary string.

#### A start time

The time, in seconds and fractions of a second, that describes the beginning of the range of the [media data](#)<sup>p328</sup> to which the cue applies.

#### An end time

The time, in seconds and fractions of a second, that describes the end of the range of the [media data](#)<sup>p328</sup> to which the cue applies.

#### A pause-on-exit flag

A boolean indicating whether playback of the [media resource](#)<sup>p328</sup> is to pause when the end of the range to which the cue applies is reached.

#### Some additional format-specific data

Additional fields, as needed for the format, including the actual data of the cue. For example, WebVTT has a [text track cue writing direction](#)<sup>p54</sup> and so forth. [\[WEBVTT\]](#)<sup>p1154</sup>

#### Rules for extracting the chapter title

An algorithm which, when applied to the cue, returns a string that can be used in user interfaces that use the cue as a chapter title.

**Note** *The [text track cue start time](#)<sup>p368</sup> and [text track cue end time](#)<sup>p368</sup> can be negative. (The [current playback position](#)<sup>p342</sup> can never be negative, though, so cues entirely before time zero cannot be active.)*

Each [text track cue](#)<sup>p368</sup> has a corresponding [TextTrackCue](#)<sup>p378</sup> object (or more specifically, an object that inherits from [TextTrackCue](#)<sup>p378</sup> — for example, WebVTT cues use the [VTCue](#)<sup>p54</sup> interface). A [text track cue](#)<sup>p368</sup>'s in-memory representation can be dynamically changed through this [TextTrackCue](#)<sup>p378</sup> API. [\[WEBVTT\]](#)<sup>p1154</sup>

A [text track cue](#)<sup>p368</sup> is associated with [rules for updating the text track rendering](#)<sup>p367</sup>, as defined by the specification for the specific kind of [text track cue](#)<sup>p368</sup>. These rules are used specifically when the object representing the cue is added to a [TextTrack](#)<sup>p374</sup> object using the [addCue\(\)](#)<sup>p376</sup> method.

In addition, each [text track cue](#)<sup>p368</sup> has two pieces of dynamic information:

#### The active flag

This flag must be initially unset. The flag is used to ensure events are fired appropriately when the cue becomes active or inactive, and to make sure the right cues are rendered.

The user agent must synchronously unset this flag whenever the [text track cue](#)<sup>p368</sup> is removed from its [text track](#)<sup>p365</sup>'s [text track list of cues](#)<sup>p367</sup>; whenever the [text track](#)<sup>p365</sup> itself is removed from its [media element](#)<sup>p326</sup>'s [list of text tracks](#)<sup>p365</sup> or has its [text track mode](#)<sup>p366</sup> changed to [disabled](#)<sup>p367</sup>; and whenever the [media element](#)<sup>p326</sup>'s [readyState](#)<sup>p345</sup> is changed back to [HAVE NOTHING](#)<sup>p343</sup>. When the flag is unset in this way for one or more cues in [text tracks](#)<sup>p365</sup> that were [showing](#)<sup>p367</sup> prior to the relevant incident, the user agent must, after having unset the flag for all the affected cues, apply the [rules for updating the text track rendering](#)<sup>p367</sup> of those [text tracks](#)<sup>p365</sup>. For example, for [text tracks](#)<sup>p365</sup> based on WebVTT, the [rules for updating the display of WebVTT text tracks](#)<sup>p54</sup>. [\[WEBVTT\]](#)<sup>p1154</sup>

#### The display state

This is used as part of the rendering model, to keep cues in a consistent position. It must initially be empty. Whenever the [text track cue active flag](#)<sup>p368</sup> is unset, the user agent must empty the [text track cue display state](#)<sup>p368</sup>.

The [text track cues](#)<sup>p368</sup> of a [media element](#)<sup>p326</sup>'s [text tracks](#)<sup>p365</sup> are ordered relative to each other in the [text track cue order](#), which is determined as follows: first group the [cues](#)<sup>p368</sup> by their [text track](#)<sup>p365</sup>, with the groups being sorted in the same order as their [text tracks](#)<sup>p365</sup> appear in the [media element](#)<sup>p326</sup>'s [list of text tracks](#)<sup>p365</sup>; then, within each group, [cues](#)<sup>p368</sup> must be sorted by their [start time](#)<sup>p368</sup>, earliest first; then, any [cues](#)<sup>p368</sup> with the same [start time](#)<sup>p368</sup> must be sorted by their [end time](#)<sup>p368</sup>, latest first; and finally, any [cues](#)<sup>p368</sup> with identical [end times](#)<sup>p368</sup> must be sorted in the order

they were last added to their respective [text track list of cues](#)<sup>p367</sup>, oldest first (so e.g. for cues from a WebVTT file, that would initially be the order in which the cues were listed in the file). [\[WEBVTT\]](#)<sup>p1154</sup>

#### 4.8.14.12.2 Sourcing in-band text tracks

A **media-resource-specific text track** is a [text track](#)<sup>p365</sup> that corresponds to data found in the [media resource](#)<sup>p328</sup>.

Rules for processing and rendering such data are defined by the relevant specifications, e.g. the specification of the video format if the [media resource](#)<sup>p328</sup> is a video. Details for some legacy formats can be found in the *Sourcing In-band Media Resource Tracks from Media Containers into HTML* specification. [\[INBAND\]](#)<sup>p1150</sup>

When a [media resource](#)<sup>p328</sup> contains data that the user agent recognises and supports as being equivalent to a [text track](#)<sup>p365</sup>, the user agent [runs](#)<sup>p339</sup> the **steps to expose a media-resource-specific text track** with the relevant data, as follows.

1. Associate the relevant data with a new [text track](#)<sup>p365</sup> and its corresponding new [TextTrack](#)<sup>p374</sup> object. The [text track](#)<sup>p365</sup> is a [media-resource-specific text track](#)<sup>p369</sup>.
2. Set the new [text track](#)<sup>p365</sup>'s [kind](#)<sup>p366</sup>, [label](#)<sup>p366</sup>, and [language](#)<sup>p366</sup> based on the semantics of the relevant data, as defined by the relevant specification. If there is no label in that data, then the [label](#)<sup>p366</sup> must be set to the empty string.
3. Associate the [text track list of cues](#)<sup>p367</sup> with the [rules for updating the text track rendering](#)<sup>p367</sup> appropriate for the format in question.
4. If the new [text track](#)<sup>p365</sup>'s [kind](#)<sup>p366</sup> is [metadata](#)<sup>p366</sup>, then set the [text track in-band metadata track dispatch type](#)<sup>p366</sup> as follows, based on the type of the [media resource](#)<sup>p328</sup>:
  - ↪ If the [media resource](#)<sup>p328</sup> is an Ogg fileThe [text track in-band metadata track dispatch type](#)<sup>p366</sup> must be set to the value of the Name header field. [\[OGGSKELETONHEADERS\]](#)<sup>p1151</sup>
  - ↪ If the [media resource](#)<sup>p328</sup> is a WebM fileThe [text track in-band metadata track dispatch type](#)<sup>p366</sup> must be set to the value of the [CodecID](#) element. [\[WEBMCG\]](#)<sup>p1154</sup>
  - ↪ If the [media resource](#)<sup>p328</sup> is an MPEG-2 fileLet *stream type* be the value of the "stream\_type" field describing the text track's type in the file's program map section, interpreted as an 8-bit unsigned integer. Let *length* be the value of the "ES\_info\_length" field for the track in the same part of the program map section, interpreted as an integer as defined by the MPEG-2 specification. Let *descriptor bytes* be the *length* bytes following the "ES\_info\_length" field. The [text track in-band metadata track dispatch type](#)<sup>p366</sup> must be set to the concatenation of the *stream type* byte and the zero or more *descriptor bytes* bytes, expressed in hexadecimal using [uppercase ASCII hex digits](#)<sup>p59</sup>. [\[MPEG2\]](#)<sup>p1151</sup>
  - ↪ If the [media resource](#)<sup>p328</sup> is an MPEG-4 fileLet the first *stsd* box of the first *stbl* box of the first *minf* box of the first *mdia* box of the [text track](#)<sup>p365</sup>'s *trak* box in the first *moov* box of the file be the *stsd box*, if any. If the file has no *stsd box*, or if the *stsd box* has neither a *mett* box nor a *metx* box, then the [text track in-band metadata track dispatch type](#)<sup>p366</sup> must be set to the empty string. Otherwise, if the *stsd box* has a *mett* box then the [text track in-band metadata track dispatch type](#)<sup>p366</sup> must be set to the concatenation of the string "*mett*", a U+0020 SPACE character, and the value of the first *mime\_format* field of the first *mett* box of the *stsd box*, or the empty string if that field is absent in that box. Otherwise, if the *stsd box* has no *mett* box but has a *metx* box then the [text track in-band metadata track dispatch type](#)<sup>p366</sup> must be set to the concatenation of the string "*metx*", a U+0020 SPACE character, and the value of the first *namespace* field of the first *metx* box of the *stsd box*, or the empty string if that field is absent in that box. [\[MPEG4\]](#)<sup>p1151</sup>
5. Populate the new [text track](#)<sup>p365</sup>'s [list of cues](#)<sup>p367</sup> with the cues parsed so far, following the [guidelines for exposing cues](#)<sup>p373</sup>, and begin updating it dynamically as necessary.
6. Set the new [text track](#)<sup>p365</sup>'s [readiness state](#)<sup>p366</sup> to [loaded](#)<sup>p366</sup>.
7. Set the new [text track](#)<sup>p365</sup>'s [mode](#)<sup>p366</sup> to the mode consistent with the user's preferences and the requirements of the relevant specification for the data.

**Note** For instance, if there are no other active subtitles, and this is a forced subtitle track (a subtitle track giving subtitles in the audio track's primary language, but only for audio that is actually in another language), then those subtitles might be activated here.

8. Add the new [text track](#) to the [media element](#)'s [list of text tracks](#).
9. [Fire](#) a [trusted](#) event with the name [addtrack](#), that does not bubble and is not cancelable, and that uses the [TrackEvent](#) interface, with the [track](#) attribute initialised to the [text track](#)'s [TextTrack](#) object, at the [media element](#)'s [textTracks](#) attribute's [TextTrackList](#) object.

#### 4.8.14.12.3 Sourcing out-of-band text tracks

When a [track](#) element is created, it must be associated with a new [text track](#) (with its value set as defined below) and its corresponding new [TextTrack](#) object.

The [text track kind](#) is determined from the state of the element's [kind](#) attribute according to the following table; for a state given in a cell of the first column, the [kind](#) is the string given in the second column:

State	String
<a href="#">Subtitles</a>	<a href="#">subtitles</a>
<a href="#">Captions</a>	<a href="#">captions</a>
<a href="#">Descriptions</a>	<a href="#">descriptions</a>
<a href="#">Chapters</a>	<a href="#">chapters</a>
<a href="#">Metadata</a>	<a href="#">metadata</a>

The [text track label](#) is the element's [track label](#).

The [text track language](#) is the element's [track language](#), if any, or the empty string otherwise.

As the [kind](#), [label](#), and [srclang](#) attributes are set, changed, or removed, the [text track](#) must update accordingly, as per the definitions above.

**Note** *Changes to the track URL* are handled in the algorithm below.

The [text track readiness state](#) is initially [not loaded](#), and the [text track mode](#) is initially [disabled](#).

The [text track list of cues](#) is initially empty. It is dynamically modified when the referenced file is parsed. Associated with the list are the [rules for updating the text track rendering](#) appropriate for the format in question; for WebVTT, this is the [rules for updating the display of WebVTT text tracks](#). [WEBVTT]<sup>1154</sup>

When a [track](#) element's parent element changes and the new parent is a [media element](#), then the user agent must add the [track](#) element's corresponding [text track](#) to the [media element](#)'s [list of text tracks](#), and then [queue a task](#) to [fire](#) a [trusted](#) event with the name [addtrack](#), that does not bubble and is not cancelable, and that uses the [TrackEvent](#) interface, with the [track](#) attribute initialised to the [text track](#)'s [TextTrack](#) object, at the [media element](#)'s [textTracks](#) attribute's [TextTrackList](#) object.

When a [track](#) element's parent element changes and the old parent was a [media element](#), then the user agent must remove the [track](#) element's corresponding [text track](#) from the [media element](#)'s [list of text tracks](#), and then [queue a task](#) to [fire](#) a [trusted](#) event with the name [removetrack](#), that does not bubble and is not cancelable, and that uses the [TrackEvent](#) interface, with the [track](#) attribute initialised to the [text track](#)'s [TextTrack](#) object, at the [media element](#)'s [textTracks](#) attribute's [TextTrackList](#) object.

When a [text track](#) corresponding to a [track](#) element is added to a [media element](#)'s [list of text tracks](#), the user agent must [queue a task](#) to run the following steps for the [media element](#):

1. If the element's [blocked-on-parser](#) flag is true, abort these steps.
2. If the element's [did-perform-automatic-track-selection](#) flag is true, abort these steps.
3. [Honor user preferences for automatic text track selection](#) for this element.

When the user agent is required to **honor user preferences for automatic text track selection** for a [media element](#), the user agent must run the following steps:

1. [Perform automatic text track selection](#)<sup>p371</sup> for [subtitles](#)<sup>p366</sup> and [captions](#)<sup>p366</sup>.
2. [Perform automatic text track selection](#)<sup>p371</sup> for [descriptions](#)<sup>p366</sup>.
3. [Perform automatic text track selection](#)<sup>p371</sup> for [chapters](#)<sup>p366</sup>.
4. If there are any [text tracks](#)<sup>p365</sup> in the [media element](#)<sup>p326</sup>'s [list of text tracks](#)<sup>p365</sup> whose [text track kind](#)<sup>p366</sup> is [metadata](#)<sup>p366</sup> that correspond to [track](#)<sup>p324</sup> elements with a [default](#)<sup>p325</sup> attribute set whose [text track mode](#)<sup>p366</sup> is set to [disabled](#)<sup>p367</sup>, then set the [text track mode](#)<sup>p366</sup> of all such tracks to [hidden](#)<sup>p367</sup>
5. Set the element's [did-perform-automatic-track-selection](#)<sup>p367</sup> flag to true.

When the steps above say to **perform automatic text track selection** for one or more [text track kinds](#)<sup>p366</sup>, it means to run the following steps:

1. Let [candidates](#) be a list consisting of the [text tracks](#)<sup>p365</sup> in the [media element](#)<sup>p326</sup>'s [list of text tracks](#)<sup>p365</sup> whose [text track kind](#)<sup>p366</sup> is one of the kinds that were passed to the algorithm, if any, in the order given in the [list of text tracks](#)<sup>p365</sup>.
2. If [candidates](#) is empty, then abort these steps.
3. If any of the [text tracks](#)<sup>p365</sup> in [candidates](#) have a [text track mode](#)<sup>p366</sup> set to [showing](#)<sup>p367</sup>, abort these steps.
4. If the user has expressed an interest in having a track from [candidates](#) enabled based on its [text track kind](#)<sup>p366</sup>, [text track language](#)<sup>p366</sup>, and [text track label](#)<sup>p366</sup>, then set its [text track mode](#)<sup>p366</sup> to [showing](#)<sup>p367</sup>.

**Note** *For example, the user could have set a browser preference to the effect of "I want French captions whenever possible", or "If there is a subtitle track with 'Commentary' in the title, enable it", or "If there are audio description tracks available, enable one, ideally in Swiss German, but failing that in Standard Swiss German or Standard German".*

Otherwise, if there are any [text tracks](#)<sup>p365</sup> in [candidates](#) that correspond to [track](#)<sup>p324</sup> elements with a [default](#)<sup>p325</sup> attribute set whose [text track mode](#)<sup>p366</sup> is set to [disabled](#)<sup>p367</sup>, then set the [text track mode](#)<sup>p366</sup> of the first such track to [showing](#)<sup>p367</sup>.

When a [text track](#)<sup>p365</sup> corresponding to a [track](#)<sup>p324</sup> element experiences any of the following circumstances, the user agent must [start the track processing model](#)<sup>p371</sup> for that [text track](#)<sup>p365</sup> and its [track](#)<sup>p324</sup> element:

- The [track](#)<sup>p324</sup> element is created.
- The [text track](#)<sup>p365</sup> has its [text track mode](#)<sup>p366</sup> changed.
- The [track](#)<sup>p324</sup> element's parent element changes and the new parent is a [media element](#)<sup>p326</sup>.

When a user agent is to [start the track processing model](#) for a [text track](#)<sup>p365</sup> and its [track](#)<sup>p324</sup> element, it must run the following algorithm. This algorithm interacts closely with the [event loop](#)<sup>b834</sup> mechanism; in particular, it has a [synchronous section](#)<sup>p837</sup> (which is triggered as part of the [event loop](#)<sup>b834</sup> algorithm). The steps in that section are marked with  $\mathbb{X}$ .

1. If another occurrence of this algorithm is already running for this [text track](#)<sup>p365</sup> and its [track](#)<sup>p324</sup> element, abort these steps, letting that other algorithm take care of this element.
2. If the [text track](#)<sup>p365</sup>'s [text track mode](#)<sup>p366</sup> is not set to one of [hidden](#)<sup>p367</sup> or [showing](#)<sup>p367</sup>, abort these steps.
3. If the [text track](#)<sup>p365</sup>'s [track](#)<sup>p324</sup> element does not have a [media element](#)<sup>p326</sup> as a parent, abort these steps.
4. Run the remainder of these steps [in parallel](#)<sup>p41</sup>, allowing whatever caused these steps to run to continue.
5. *Top: Await a stable state*<sup>p837</sup>. The [synchronous section](#)<sup>p837</sup> consists of the following steps. (The steps in the [synchronous section](#)<sup>p837</sup> are marked with  $\mathbb{X}$ .)
  6.  $\mathbb{X}$  Set the [text track readiness state](#)<sup>p366</sup> to [loading](#)<sup>p366</sup>.
  7.  $\mathbb{X}$  Let [URL](#) be the [track URL](#)<sup>p325</sup> of the [track](#)<sup>p324</sup> element.
  8.  $\mathbb{X}$  If the [track](#)<sup>p324</sup> element's parent is a [media element](#)<sup>p326</sup> then let [CORS mode](#) be the state of the parent [media element](#)<sup>p326</sup>'s [crossorigin](#)<sup>p329</sup> content attribute. Otherwise, let [CORS mode](#) be [No CORS](#)<sup>p87</sup>.
9. End the [synchronous section](#)<sup>p837</sup>, continuing the remaining steps [in parallel](#)<sup>p41</sup>.

- If *URL* is not the empty string, perform a [potentially CORS-enabled fetch<sup>p87</sup>](#) of *URL*, with the *mode* being CORS mode, the *origin* being the [origin<sup>p776</sup>](#) of the [track<sup>p324</sup>](#) element's [node document](#), and the default origin behaviour set to fail.

The resource obtained in this fashion, if any, contains the text track data. If any data is obtained, it is by definition [CORS-same-origin<sup>p87</sup>](#) (cross-origin resources that are not suitably CORS-enabled do not get this far).

The [tasks<sup>p834</sup>](#) [queued<sup>p835</sup>](#) by the [fetching algorithm<sup>p84</sup>](#) on the [networking task source<sup>p839</sup>](#) to process the data as it is being fetched must determine the type of the resource. If the type of the resource is not a supported text track format, the load will fail, as described below. Otherwise, the resource's data must be passed to the appropriate parser (e.g. the [WebVTT parser<sup>p54</sup>](#)) as it is received, with the [text track list of cues<sup>p367</sup>](#) being used for that parser's output. [\[WEBVTT\]<sup>p1154</sup>](#)

**Note** *The appropriate parser will incrementally update the text track list of cues<sup>p367</sup> during these networking task source<sup>p839</sup> tasks<sup>p834</sup>, as each such task is run with whatever data has been received from the network.*

This specification does not currently say whether or how to check the MIME types of text tracks, or whether or how to perform file type sniffing using the actual file data. Implementors differ in their intentions on this matter and it is therefore unclear what the right solution is. In the absence of any requirement here, the HTTP specification's strict requirement to follow the Content-Type header prevails ("Content-Type specifies the media type of the underlying data." ... "If and only if the media type is not given by a Content-Type field, the recipient MAY attempt to guess the media type via inspection of its content and/or the name extension(s) of the URI used to identify the resource.").

If the [fetching algorithm<sup>p84</sup>](#) fails for any reason (network error, the server returns an error code, a cross-origin check fails, etc), or if *URL* is the empty string, then [queue a task<sup>p835</sup>](#) to first change the [text track readiness state<sup>p366</sup>](#) to [failed to load<sup>p366</sup>](#) and then [fire a simple event<sup>p846</sup>](#) named [error<sup>p1144</sup>](#) at the [track<sup>p324</sup>](#) element. This [task<sup>p834</sup>](#) must use the [DOM manipulation task source<sup>p838</sup>](#).

If the [fetching algorithm<sup>p84</sup>](#) does not fail, but the type of the resource is not a supported text track format, or the file was not successfully processed (e.g. the format in question is an XML format and the file contained a well-formedness error that the XML specification requires be detected and reported to the application), then the [task<sup>p834</sup>](#) that is [queued<sup>p835</sup>](#) by the [networking task source<sup>p839</sup>](#) in which the aforementioned problem is found must change the [text track readiness state<sup>p366</sup>](#) to [failed to load<sup>p366</sup>](#) and [fire a simple event<sup>p846</sup>](#) named [error<sup>p1144</sup>](#) at the [track<sup>p324</sup>](#) element.

If the [fetching algorithm<sup>p84</sup>](#) does not fail, and the file was successfully processed, then the final [task<sup>p834</sup>](#) that is [queued<sup>p835</sup>](#) by the [networking task source<sup>p839</sup>](#), after it has finished parsing the data, must change the [text track readiness state<sup>p366</sup>](#) to [loaded<sup>p366</sup>](#), and [fire a simple event<sup>p846</sup>](#) named [load<sup>p1144</sup>](#) at the [track<sup>p324</sup>](#) element.

If, while the [fetching algorithm<sup>p84</sup>](#) is active, either:

- the [track URL<sup>p325</sup>](#) changes so that it is no longer equal to *URL*, while the [text track mode<sup>p366</sup>](#) is set to [hidden<sup>p367</sup>](#) or [showing<sup>p367</sup>](#); or
- the [text track mode<sup>p366</sup>](#) changes to [hidden<sup>p367</sup>](#) or [showing<sup>p367</sup>](#), while the [track URL<sup>p325</sup>](#) is not equal to *URL*

...then the user agent must abort the [fetching algorithm<sup>p84</sup>](#), discarding any pending [tasks<sup>p834</sup>](#) generated by that algorithm (and in particular, not adding any cues to the [text track list of cues<sup>p367</sup>](#) after the moment the URL changed), and then [queue a task<sup>p835</sup>](#) that first changes the [text track readiness state<sup>p366</sup>](#) to [failed to load<sup>p366</sup>](#) and then [fires a simple event<sup>p846</sup>](#) named [error<sup>p1144</sup>](#) at the [track<sup>p324</sup>](#) element. This [task<sup>p834</sup>](#) must use the [DOM manipulation task source<sup>p838</sup>](#).

- Wait until the [text track readiness state<sup>p366</sup>](#) is no longer set to [loading<sup>p366</sup>](#).
- Wait until the [track URL<sup>p325</sup>](#) is no longer equal to *URL*, at the same time as the [text track mode<sup>p366</sup>](#) is set to [hidden<sup>p367</sup>](#) or [showing<sup>p367</sup>](#).
- Jump to the step labeled *top*.

Whenever a [track<sup>p324</sup>](#) element has its [src<sup>p325</sup>](#) attribute set, changed, or removed, the user agent must [immediately<sup>p41</sup>](#) empty the element's [text track<sup>p365</sup>](#)'s [text track list of cues<sup>p367</sup>](#). (This also causes the algorithm above to stop adding cues from the resource being obtained using the previously given URL, if any.)

#### 4.8.14.12.4 Guidelines for exposing cues in various formats as [text track cues](#)<sup>p368</sup>

How a specific format's text track cues are to be interpreted for the purposes of processing by an HTML user agent is defined by that format. In the absence of such a specification, this section provides some constraints within which implementations can attempt to consistently expose such formats.

To support the [text track](#)<sup>p365</sup> model of HTML, each unit of timed data is converted to a [text track cue](#)<sup>p368</sup>. Where the mapping of the format's features to the aspects of a [text track cue](#)<sup>p368</sup> as defined in this specification are not defined, implementations must ensure that the mapping is consistent with the definitions of the aspects of a [text track cue](#)<sup>p368</sup> as defined above, as well as with the following constraints:

##### The [text track cue identifier](#)<sup>p368</sup>

Should be set to the empty string if the format has no obvious analogue to a per-cue identifier.

##### The [text track cue pause-on-exit flag](#)<sup>p368</sup>

Should be set to false.

#### 4.8.14.12.5 Text track API

##### IDL

```
interface TextTrackList : EventTarget {
 readonly attribute unsigned long length;
 getter TextTrack (unsigned long index);
 TextTrack? getTrackById(DOMString id);

 attribute EventHandler onchange;
 attribute EventHandler onaddtrack;
 attribute EventHandler onremovetrack;
};
```

##### Note

**media . textTracks<sup>p373</sup> . length**

Returns the number of [text tracks](#)<sup>p365</sup> associated with the [media element](#)<sup>p326</sup> (e.g. from [track](#)<sup>p324</sup> elements). This is the number of [text tracks](#)<sup>p365</sup> in the [media element](#)<sup>p326</sup>'s [list of text tracks](#)<sup>p365</sup>.

**media . textTracks<sup>p373</sup> [ *n* ]**

Returns the [TextTrack](#)<sup>p374</sup> object representing the *n*th [text track](#)<sup>p365</sup> in the [media element](#)<sup>p326</sup>'s [list of text tracks](#)<sup>p365</sup>.

**textTrack = media . textTracks<sup>p373</sup> . getTrackById<sup>p373</sup> ( *id* )**

Returns the [TextTrack](#)<sup>p374</sup> object with the given identifier, or null if no track has that identifier.

A [TextTrackList](#)<sup>p373</sup> object represents a dynamically updating list of [text tracks](#)<sup>p365</sup> in a given order.

The [textTracks](#) attribute of [media elements](#)<sup>p326</sup> must return a [TextTrackList](#)<sup>p373</sup> object representing the [TextTrack](#)<sup>p374</sup> objects of the [text tracks](#)<sup>p365</sup> in the [media element](#)<sup>p326</sup>'s [list of text tracks](#)<sup>p365</sup>, in the same order as in the [list of text tracks](#)<sup>p365</sup>.

The [length](#) attribute of a [TextTrackList](#)<sup>p373</sup> object must return the number of [text tracks](#)<sup>p365</sup> in the list represented by the [TextTrackList](#)<sup>p373</sup> object.

The [supported property indices](#)<sup>p49</sup> of a [TextTrackList](#)<sup>p373</sup> object at any instant are the numbers from zero to the number of [text tracks](#)<sup>p365</sup> in the list represented by the [TextTrackList](#)<sup>p373</sup> object minus one, if any. If there are no [text tracks](#)<sup>p365</sup> in the list, there are no [supported property indices](#)<sup>p49</sup>.

To [determine the value of an indexed property](#)<sup>p49</sup> of a [TextTrackList](#)<sup>p373</sup> object for a given index *index*, the user agent must return the *index*th [text track](#)<sup>p365</sup> in the list represented by the [TextTrackList](#)<sup>p373</sup> object.

The [getTrackById](#) (*id*) method must return the first [TextTrack](#)<sup>p374</sup> in the [TextTrackList](#)<sup>p373</sup> object whose [id](#)<sup>p375</sup> IDL attribute would return a value equal to the value of the *id* argument. When no tracks match the given argument, the method must return null.

```

IDL
enum TextTrackMode { "disabled", "hidden", "showing" };
enum TextTrackKind { "subtitles", "captions", "descriptions", "chapters", "metadata" };
interface TextTrack : EventTarget {
 readonly attribute TextTrackKind kind;
 readonly attribute DOMString label;
 readonly attribute DOMString language;

 readonly attribute DOMString id;
 readonly attribute DOMString inBandMetadataTrackDispatchType;

 attribute TextTrackMode mode;

 readonly attribute TextTrackCueList? cues;
 readonly attribute TextTrackCueList? activeCues;

 void addCue(TextTrackCue cue);
 void removeCue(TextTrackCue cue);

 attribute EventHandler oncuechange;
};

```

### Note

**textTrack = media . addTextTrack<sup>p375</sup>( kind [, label [, language ] ] )**

Creates and returns a new TextTrack<sup>p374</sup> object, which is also added to the media element<sup>p326</sup>'s list of text tracks<sup>p365</sup>.

**textTrack . kind<sup>p375</sup>**

Returns the text track kind<sup>p366</sup> string.

**textTrack . label<sup>p375</sup>**

Returns the text track label<sup>p366</sup>, if there is one, or the empty string otherwise (indicating that a custom label probably needs to be generated from the other attributes of the object if the object is exposed to the user).

**textTrack . language<sup>p375</sup>**

Returns the text track language<sup>p366</sup> string.

**textTrack . id<sup>p375</sup>**

Returns the ID of the given track.

For in-band tracks, this is the ID that can be used with a fragment identifier if the format supports the *Media Fragments URI* syntax, and that can be used with the getTrackById()<sup>p373</sup> method. [MEDIAFRAG]<sup>p1151</sup>

For TextTrack<sup>p374</sup> objects corresponding to track<sup>p324</sup> elements, this is the ID of the track<sup>p324</sup> element.

**textTrack . inBandMetadataTrackDispatchType<sup>p375</sup>**

Returns the text track in-band metadata track dispatch type<sup>p366</sup> string.

**textTrack . mode<sup>p375</sup> [ = value ]**

Returns the text track mode<sup>p366</sup>, represented by a string from the following list:

"disabled"<sup>p375</sup>"

The text track disabled<sup>p367</sup> mode.

"hidden"<sup>p375</sup>"

The text track hidden<sup>p367</sup> mode.

"showing"<sup>p376</sup>"

The text track showing<sup>p367</sup> mode.

Can be set, to change the mode.

**`textTrack.cuesp376`**

Returns the [text track list of cues<sup>p367</sup>](#), as a [TextTrackCueList<sup>p377</sup>](#) object.

**`textTrack.activeCuesp376`**

Returns the [text track cues<sup>p368</sup>](#) from the [text track list of cues<sup>b367</sup>](#) that are currently active (i.e. that start before the [current playback position<sup>p342</sup>](#) and end after it), as a [TextTrackCueList<sup>p377</sup>](#) object.

**`textTrack.addCuep376( cue )`**

Adds the given cue to `textTrack`'s [text track list of cues<sup>p367</sup>](#).

**`textTrack.removeCuep376( cue )`**

Removes the given cue from `textTrack`'s [text track list of cues<sup>p367</sup>](#).

The [addTextTrack\(`kind`, `label`, `language`\)](#) method of [media elements<sup>p326</sup>](#), when invoked, must run the following steps:

1. Create a new [TextTrack<sup>p374</sup>](#) object.
2. Create a new [text track<sup>p365</sup>](#) corresponding to the new object, and set its [text track kind<sup>p366</sup>](#) to `kind`, its [text track label<sup>p366</sup>](#) to `label`, its [text track language<sup>b366</sup>](#) to `language`, its [text track readiness state<sup>p366</sup>](#) to the [text track loaded<sup>p366</sup>](#) state, its [text track mode<sup>p366</sup>](#) to the [text track hidden<sup>p367</sup>](#) mode, and its [text track list of cues<sup>p367</sup>](#) to an empty list.

Initially, the [text track list of cues<sup>p367</sup>](#) is not associated with any [rules for updating the text track rendering<sup>p367</sup>](#). When a [text track cue<sup>p368</sup>](#) is added to it, the [text track list of cues<sup>p367</sup>](#) has its rules permanently set accordingly.
3. Add the new [text track<sup>p365</sup>](#) to the [media element<sup>p326</sup>](#)'s [list of text tracks<sup>p365</sup>](#).
4. [Queue a task<sup>p385</sup>](#) to [fire<sup>p43</sup>](#) a [trusted<sup>p43</sup>](#) event with the name [addrtrack<sup>p387</sup>](#), that does not bubble and is not cancelable, and that uses the [TrackEvent<sup>p385</sup>](#) interface, with the [track<sup>p385</sup>](#) attribute initialised to the new [text track<sup>p365</sup>](#)'s [TextTrack<sup>p374</sup>](#) object, at the [media element<sup>p326</sup>](#)'s [textTracks<sup>p373</sup>](#) attribute's [TextTrackList<sup>p373</sup>](#) object.
5. Return the new [TextTrack<sup>p374</sup>](#) object.

The `kind` attribute must return the [text track kind<sup>p366</sup>](#) of the [text track<sup>p365</sup>](#) that the [TextTrack<sup>b374</sup>](#) object represents.

The `label` attribute must return the [text track label<sup>p366</sup>](#) of the [text track<sup>p365</sup>](#) that the [TextTrack<sup>p374</sup>](#) object represents.

The `language` attribute must return the [text track language<sup>p366</sup>](#) of the [text track<sup>p365</sup>](#) that the [TextTrack<sup>b374</sup>](#) object represents.

The `id` attribute returns the track's identifier, if it has one, or the empty string otherwise. For tracks that correspond to [track<sup>p324</sup>](#) elements, the track's identifier is the value of the element's [id<sup>p122</sup>](#) attribute, if any. For in-band tracks, the track's identifier is specified by the [media resource<sup>p328</sup>](#). If the [media resource<sup>p328</sup>](#) is in a format that supports the *Media Fragments URI* fragment identifier syntax, the identifier returned for a particular track must be the same identifier that would enable the track if used as the name of a track in the track dimension of such a fragment identifier.

[\[MEDIAFRAG\]<sup>p1151</sup>](#)

The `inBandMetadataTrackDispatchType` attribute must return the [text track in-band metadata track dispatch type<sup>p366</sup>](#) of the [text track<sup>p365</sup>](#) that the [TextTrack<sup>p374</sup>](#) object represents.

The `mode` attribute, on getting, must return the string corresponding to the [text track mode<sup>p366</sup>](#) of the [text track<sup>p365</sup>](#) that the [TextTrack<sup>p374</sup>](#) object represents, as defined by the following list:

**"disabled"**

The [text track disabled<sup>p367</sup>](#) mode.

**"hidden"**

The [text track hidden<sup>p367</sup>](#) mode.

"**showing**"

The [text track showing](#) mode.

On setting, if the new value isn't equal to what the attribute would currently return, the new value must be processed as follows:

↪ If the new value is "[disabled](#)"

Set the [text track mode](#) of the [text track](#) that the [TextTrack](#) object represents to the [text track disabled](#) mode.

↪ If the new value is "[hidden](#)"

Set the [text track mode](#) of the [text track](#) that the [TextTrack](#) object represents to the [text track hidden](#) mode.

↪ If the new value is "[showing](#)"

Set the [text track mode](#) of the [text track](#) that the [TextTrack](#) object represents to the [text track showing](#) mode.

If the [text track mode](#) of the [text track](#) that the [TextTrack](#) object represents is not the [text track disabled](#) mode, then the [cues](#) attribute must return a [live](#) [TextTrackCueList](#) object that represents the subset of the [text track list of cues](#) of the [text track](#) that the [TextTrack](#) object represents whose [end times](#) occur at or after the [earliest possible position when the script started](#), in [text track cue order](#). Otherwise, it must return null. For each [TextTrack](#) object, when an object is returned, the same [TextTrackCueList](#) object must be returned each time.

The **earliest possible position when the script started** is whatever the [earliest possible position](#) was the last time the [event loop](#) reached step 1.

If the [text track mode](#) of the [text track](#) that the [TextTrack](#) object represents is not the [text track disabled](#) mode, then the [activeCues](#) attribute must return a [live](#) [TextTrackCueList](#) object that represents the subset of the [text track list of cues](#) of the [text track](#) that the [TextTrack](#) object represents whose [active flag was set when the script started](#), in [text track cue order](#). Otherwise, it must return null. For each [TextTrack](#) object, when an object is returned, the same [TextTrackCueList](#) object must be returned each time.

A [text track cue](#)'s [active flag was set when the script started](#) if its [text track cue active flag](#) was set the last time the [event loop](#) reached [step 1](#).

The [addCue \(cue\)](#) method of [TextTrack](#) objects, when invoked, must run the following steps:

1. If the [text track list of cues](#) does not yet have any associated [rules for updating the text track rendering](#), then associate the [text track list of cues](#) with the [rules for updating the text track rendering](#) appropriate to [cue](#).
2. If [text track list of cues](#)' associated [rules for updating the text track rendering](#) are not the same [rules for updating the text track rendering](#) as appropriate for [cue](#), then throw an [InvalidStateError](#) exception and abort these steps.
3. If the given [cue](#) is in a [text track list of cues](#), then remove [cue](#) from that [text track list of cues](#).
4. Add [cue](#) to the method's [TextTrack](#) object's [text track](#)'s [text track list of cues](#).

The [removeCue \(cue\)](#) method of [TextTrack](#) objects, when invoked, must run the following steps:

1. If the given [cue](#) is not currently listed in the method's [TextTrack](#) object's [text track](#)'s [text track list of cues](#), then throw a [NotFoundError](#) exception and abort these steps.
2. Remove [cue](#) from the method's [TextTrack](#) object's [text track](#)'s [text track list of cues](#).

### Example

In this example, an [audio](#) element is used to play a specific sound-effect from a sound file containing many sound effects. A cue is used to pause the audio, so that it ends exactly at the end of the clip, even if the browser is busy running some script. If the page had relied on script to pause the audio, then the start of the next clip might be heard if the browser was not able to run the script at the exact time specified.

```
var sfx = new Audio('sfx.wav');
var sounds = sfx.addTextTrack('metadata');

// add sounds we care about
```

```

function addFX(start, end, name) {
 var cue = new VTTcue(start, end, '');
 cue.id = name;
 cue.pauseOnExit = true;
 sounds.addCue(cue);
}
addFX(12.783, 13.612, 'dog bark');
addFX(13.612, 15.091, 'kitten mew'))

function playSound(id) {
 sfx.currentTime = sounds.getCueById(id).startTime;
 sfx.play();
}

// play a bark as soon as we can
sfx.oncanplaythrough = function () {
 playSound('dog bark');
}
// meow when the user tries to leave
window.onbeforeunload = function () {
 playSound('kitten mew');
 return 'Are you sure you want to leave this awesome page?';
}

```

#### IDL

```

interface TextTrackCueList {
 readonly attribute unsigned long length;
 getter TextTrackCue (unsigned long index);
 TextTrackCue? getcueById(DOMString id);
};

```

#### Note

**cuelist.length**<sup>p377</sup>

Returns the number of **cues**<sup>p368</sup> in the list.

**cuelist[index]**

Returns the **text track cue**<sup>p368</sup> with index *index* in the list. The cues are sorted in **text track cue order**<sup>p368</sup>.

**cuelist.getcueById**<sup>p377</sup>(*id*)

Returns the first **text track cue**<sup>p368</sup> (in **text track cue order**<sup>p368</sup>) with **text track cue identifier**<sup>p368</sup> *id*.

Returns null if none of the cues have the given identifier or if the argument is the empty string.

A **TextTrackCueList**<sup>p377</sup> object represents a dynamically updating list of **text track cues**<sup>p368</sup> in a given order.

The **length** attribute must return the number of **cues**<sup>p368</sup> in the list represented by the **TextTrackCueList**<sup>p377</sup> object.

The **supported property indices**<sup>p49</sup> of a **TextTrackCueList**<sup>p377</sup> object at any instant are the numbers from zero to the number of **cues**<sup>p368</sup> in the list represented by the **TextTrackCueList**<sup>p377</sup> object minus one, if any. If there are no **cues**<sup>p368</sup> in the list, there are no **supported property indices**<sup>p49</sup>.

To **determine the value of an indexed property**<sup>p49</sup> for a given index *index*, the user agent must return the *index*th **text track cue**<sup>p368</sup> in the list represented by the **TextTrackCueList**<sup>p377</sup> object.

The **getcueById**(*id*) method, when called with an argument other than the empty string, must return the first **text track cue**<sup>p368</sup> in the list represented by the **TextTrackCueList**<sup>p377</sup> object whose **text track cue identifier**<sup>p368</sup> is *id*, if any, or null otherwise. If the argument is the empty string, then the method must return null.

## IDL

```
interface TextTrackCue : EventTarget {
 readonly attribute TextTrack? track;
```

attribute **DOMString** **id**;

attribute **double** **startTime**;

attribute **double** **endTime**;

attribute **boolean** **pauseOnExit**;

attribute **EventHandler** **onenter**;

attribute **EventHandler** **onexit**;

};

## Note

**cue . track**<sup>p378</sup>

Returns the [TextTrack](#)<sup>p374</sup> object to which this [text track cue](#)<sup>p368</sup> belongs, if any, or null otherwise.

**cue . id**<sup>p378</sup> [ = *value* ]

Returns the [text track cue identifier](#)<sup>p368</sup>.

Can be set.

**cue . startTime**<sup>p378</sup> [ = *value* ]

Returns the [text track cue start time](#)<sup>p368</sup>, in seconds.

Can be set.

**cue . endTime**<sup>p378</sup> [ = *value* ]

Returns the [text track cue end time](#)<sup>p368</sup>, in seconds.

Can be set.

**cue . pauseOnExit**<sup>p378</sup> [ = *value* ]

Returns true if the [text track cue pause-on-exit flag](#)<sup>p368</sup> is set, false otherwise.

Can be set.

The **track** attribute, on getting, must return the [TextTrack](#)<sup>p374</sup> object of the [text track](#)<sup>p365</sup> in whose [list of cues](#)<sup>p367</sup> the [text track cue](#)<sup>p368</sup> that the [TextTrackCue](#)<sup>p378</sup> object represents finds itself, if any; or null otherwise.

The **id** attribute, on getting, must return the [text track cue identifier](#)<sup>p368</sup> of the [text track cue](#)<sup>p368</sup> that the [TextTrackCue](#)<sup>p378</sup> object represents. On setting, the [text track cue identifier](#)<sup>p368</sup> must be set to the new value.

The **startTime** attribute, on getting, must return the [text track cue start time](#)<sup>p368</sup> of the [text track cue](#)<sup>p368</sup> that the [TextTrackCue](#)<sup>p378</sup> object represents, in seconds. On setting, the [text track cue start time](#)<sup>p368</sup> must be set to the new value, interpreted in seconds; then, if the [TextTrackCue](#)<sup>p378</sup> object's [text track cue](#)<sup>p368</sup> is in a [text track](#)<sup>p365</sup>'s [list of cues](#)<sup>p367</sup>, and that [text track](#)<sup>p365</sup> is in a [media element](#)<sup>p326</sup>'s [list of text tracks](#)<sup>p365</sup>, and the [media element](#)<sup>p326</sup>'s [show poster flag](#)<sup>p342</sup> is not set, then run the [time marches on](#)<sup>p349</sup> steps for that [media element](#)<sup>p326</sup>.

The **endTime** attribute, on getting, must return the [text track cue end time](#)<sup>p368</sup> of the [text track cue](#)<sup>p368</sup> that the [TextTrackCue](#)<sup>p378</sup> object represents, in seconds. On setting, the [text track cue end time](#)<sup>p368</sup> must be set to the new value, interpreted in seconds; then, if the [TextTrackCue](#)<sup>p378</sup> object's [text track cue](#)<sup>p368</sup> is in a [text track](#)<sup>p365</sup>'s [list of cues](#)<sup>p367</sup>, and that [text track](#)<sup>p365</sup> is in a [media element](#)<sup>p326</sup>'s [list of text tracks](#)<sup>p365</sup>, and the [media element](#)<sup>p326</sup>'s [show poster flag](#)<sup>p342</sup> is not set, then run the [time marches on](#)<sup>p349</sup> steps for that [media element](#)<sup>p326</sup>.

The **pauseOnExit** attribute, on getting, must return true if the [text track cue pause-on-exit flag](#)<sup>p368</sup> of the [text track cue](#)<sup>p368</sup> that the [TextTrackCue](#)<sup>p378</sup> object represents is set; or false otherwise. On setting, the [text track cue pause-on-exit flag](#)<sup>p368</sup> must be set if the new value is true, and must be unset otherwise.

#### 4.8.14.12.6 Text tracks describing chapters

Chapters are segments of a [media resource](#)<sup>p328</sup> with a given title. Chapters can be nested, in the same way that sections in a document outline can have subsections.

Each [text track cue](#)<sup>p368</sup> in a [text track](#)<sup>p365</sup> being used for describing chapters has three key features: the [text track cue start time](#)<sup>p368</sup>, giving the start time of the chapter, the [text track cue end time](#)<sup>p368</sup>, giving the end time of the chapter, and the [text track rules for extracting the chapter title](#)<sup>p368</sup>.

The **rules for constructing the chapter tree from a text track** are as follows. They produce a potentially nested list of chapters, each of which have a start time, end time, title, and a list of nested chapters. This algorithm discards cues that do not correctly nest within each other, or that are out of order.

1. Let *list* be a copy of the [list of cues](#)<sup>p367</sup> of the [text track](#)<sup>p365</sup> being processed.
2. Remove from *list* any [text track cue](#)<sup>p368</sup> whose [text track cue end time](#)<sup>p368</sup> is before its [text track cue start time](#)<sup>p368</sup>.
3. Let *output* be an empty list of chapters, where a chapter is a record consisting of a start time, an end time, a title, and a (potentially empty) list of nested chapters. For the purpose of this algorithm, each chapter also has a parent chapter.
4. Let *current chapter* be a stand-in chapter whose start time is negative infinity, whose end time is positive infinity, and whose list of nested chapters is *output*. (This is just used to make the algorithm easier to describe.)
5. *Loop*: If *list* is empty, jump to the step labeled *end*.
6. Let *current cue* be the first cue in *list*, and then remove it from *list*.
7. If *current cue*'s [text track cue start time](#)<sup>p368</sup> is less than the start time of *current chapter*, then return to the step labeled *loop*.
8. While *current cue*'s [text track cue start time](#)<sup>p368</sup> is greater than or equal to *current chapter*'s end time, let *current chapter* be *current chapter*'s parent chapter.
9. If *current cue*'s [text track cue end time](#)<sup>p368</sup> is greater than the end time of *current chapter*, then return to the step labeled *loop*.
10. Create a new chapter *new chapter*, whose start time is *current cue*'s [text track cue start time](#)<sup>p368</sup>, whose end time is *current cue*'s [text track cue end time](#)<sup>p368</sup>, whose title is the result of running *current cue*'s [text track rules for extracting the chapter title](#)<sup>p368</sup>, and whose list of nested chapters is empty.
11. Append *new chapter* to *current chapter*'s list of nested chapters, and let *current chapter* be *new chapter*'s parent.
12. Let *current chapter* be *new chapter*.
13. Return to the step labeled *loop*.
14. *End*: Return *output*.

#### Example

The following snippet of a [WebVTT file](#)<sup>p54</sup> shows how nested chapters can be marked up. The file describes three 50-minute chapters, "Astrophysics", "Computational Physics", and "General Relativity". The first has three subchapters, the second has four, and the third has two. [\[WEBVTT\]](#)<sup>p154</sup>

```

#### 4.8.14.12.7 Event handlers for objects of the text track APIs

The following are the [event handlers<sup>p839</sup>](#) that (and their corresponding [event handler event types<sup>p839</sup>](#)) must be supported, as [event handler IDL attributes<sup>p839</sup>](#), by all objects implementing the [TextTrackList<sup>p373</sup>](#) interface:

<a href="#">Event handler<sup>p839</sup></a>	<a href="#">Event handler event type<sup>p839</sup></a>
<code>onchange</code>	<a href="#">change<sup>p387</sup></a>
<code>onaddtrack</code>	<a href="#">addtrack<sup>p387</sup></a>
<code>onremovetrack</code>	<a href="#">removetrack<sup>p387</sup></a>

The following are the [event handlers<sup>p839</sup>](#) that (and their corresponding [event handler event types<sup>p839</sup>](#)) must be supported, as [event handler IDL attributes<sup>p839</sup>](#), by all objects implementing the [TextTrack<sup>p374</sup>](#) interface:

<a href="#">Event handler<sup>p839</sup></a>	<a href="#">Event handler event type<sup>p839</sup></a>
<code>oncuechange</code>	<a href="#">cuechange<sup>p387</sup></a>

The following are the [event handlers<sup>p839</sup>](#) that (and their corresponding [event handler event types<sup>p839</sup>](#)) must be supported, as [event handler IDL attributes<sup>p839</sup>](#), by all objects implementing the [TextTrackCue<sup>p378</sup>](#) interface:

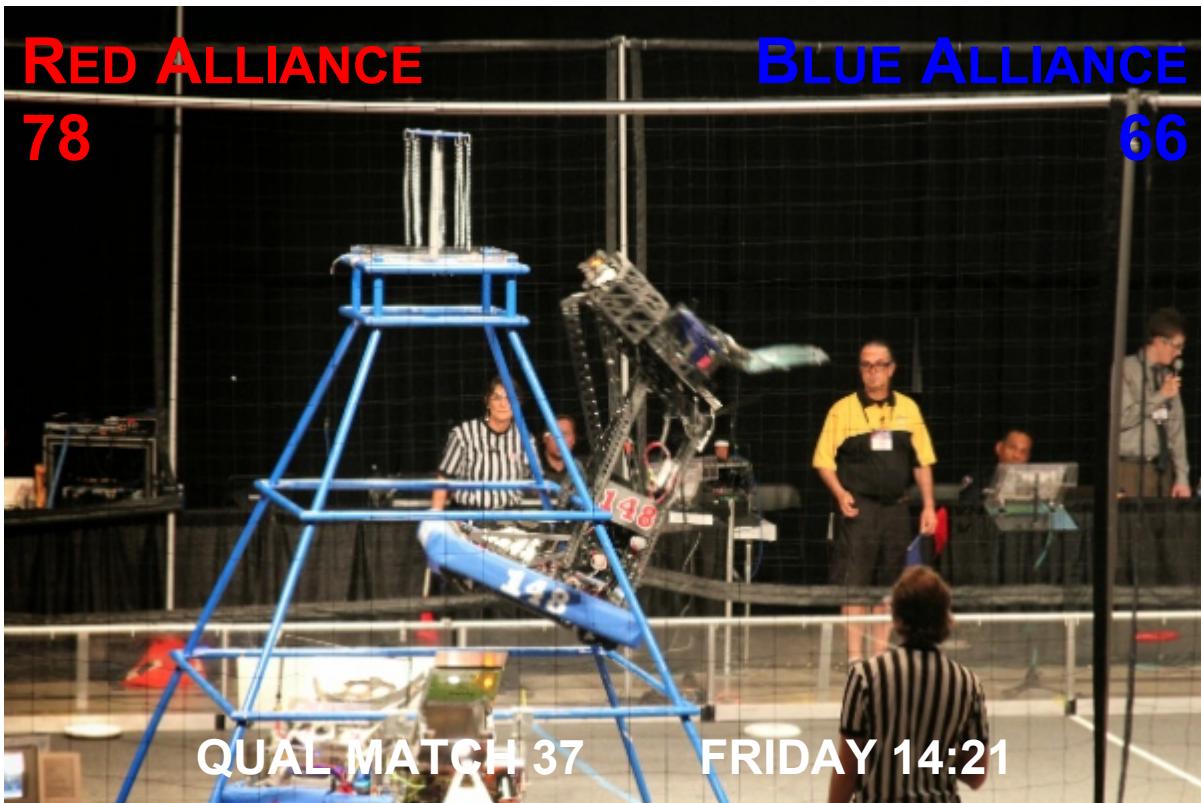

<a href="#">Event handler<sup>p839</sup></a>	<a href="#">Event handler event type<sup>p839</sup></a>
<code>onenter</code>	<a href="#">enter<sup>p387</sup></a>
<code>onexit</code>	<a href="#">exit<sup>p387</sup></a>

#### 4.8.14.12.8 Best practices for metadata text tracks

*This section is non-normative.*

Text tracks can be used for storing data relating to the media data, for interactive or augmented views.

For example, a page showing a sports broadcast could include information about the current score. Suppose a robotics competition was being streamed live. The image could be overlayed with the scores, as follows:

In order to make the score display render correctly whenever the user seeks to an arbitrary point in the video, the metadata text track cues need to be as long as is appropriate for the score. For example, in the frame above, there would be maybe one cue that lasts the length of the match that gives the match number, one cue that lasts until the blue alliance's score changes, and one cue that lasts until the red alliance's score changes. If the video is just a stream of the live event, the time in the bottom right would presumably be automatically derived from the current video time, rather than based on a cue. However, if the video was just the highlights, then that might be given in cues also.

The following shows what fragments of this could look like in a WebVTT file:

WEBVTT

...

05:10:00.000 --> 05:12:15.000

matchtype:qual  
matchnumber:37

...

05:11:02.251 --> 05:11:17.198

red:78

05:11:03.672 --> 05:11:54.198

blue:66

05:11:17.198 --> 05:11:25.912

red:80

05:11:25.912 --> 05:11:26.522

red:83

05:11:26.522 --> 05:11:26.982

red:86

05:11:26.982 --> 05:11:27.499

...

The key here is to notice that the information is given in cues that span the length of time to which the relevant event applies. If, instead, the scores were given as zero-length (or very brief, nearly zero-length) cues when the score changes, for example saying "red+2" at 05:11:17.198, "red+3" at 05:11:25.912, etc, problems arise: primarily, seeking is much harder to implement, as the script has to walk the entire list of cues to make sure that no notifications have been missed; but also, if the cues are short it's possible the script will never see that they are active unless it listens to them specifically.

When using cues in this manner, authors are encouraged to use the [cuechange<sup>p387</sup>](#) event to update the current annotations. (In particular, using the [timeupdate<sup>p387</sup>](#) event would be less appropriate as it would require doing work even when the cues haven't changed, and, more importantly, would introduce a higher latency between when the metadata cues become active and when the display is updated, since [timeupdate<sup>p387</sup>](#) events are rate-limited.)

#### 4.8.14.13 User interface

The [controls](#) attribute is a [boolean attribute<sup>p59</sup>](#). If present, it indicates that the author has not provided a scripted controller and would like the user agent to provide its own set of controls.

If the attribute is present, or if [scripting is disabled<sup>p828</sup>](#) for the [media element<sup>p326</sup>](#), then the user agent should **expose a user interface to the user**. This user interface should include features to begin playback, pause playback, seek to an arbitrary position in the content (if the content supports arbitrary seeking), change the volume, change the display of closed captions or embedded sign-language tracks, select different audio tracks or turn on audio descriptions, and show the media content in manners more suitable to the user (e.g. full-screen video or in an independent resizable window). Other controls may also be made available.

If the [media element<sup>p326</sup>](#) has a [current media controller<sup>p360</sup>](#), then the user agent should expose audio tracks from all the [slaved media elements<sup>p360</sup>](#) (although avoiding duplicates if the same [media resource<sup>p328</sup>](#) is being used several times). If a [media resource<sup>p328</sup>](#)'s audio track exposed in this way has no known name, and it is the only audio track for a particular [media element<sup>p326</sup>](#), the user agent should use the element's [title<sup>p122</sup>](#) attribute, if any, as the name (or as part of the name) of that track.

Even when the attribute is absent, however, user agents may provide controls to affect playback of the media resource (e.g. play, pause, seeking, and volume controls), but such features should not interfere with the page's normal rendering. For example, such features could be exposed in the [media element<sup>p326</sup>](#)'s context menu. The user agent may implement this simply by [exposing a user interface to the user<sup>p382</sup>](#) as described above (as if the [controls<sup>p382</sup>](#) attribute was present).

If the user agent [exposes a user interface to the user<sup>p382</sup>](#) by displaying controls over the [media element<sup>p326</sup>](#), then the user agent should suppress any user interaction events while the user agent is interacting with this interface. (For example, if the user clicks on a video's playback control, [mousedown<sup>p52</sup>](#) events and so forth would not simultaneously be fired at elements on the page.)

Where possible (specifically, for starting, stopping, pausing, and unpauseing playback, for seeking, for changing the rate of playback, for fast-forwarding or rewinding, for listing, enabling, and disabling text tracks, and for muting or changing the volume of the audio), user interface features exposed by the user agent must be implemented in terms of the DOM API described above, so that, e.g., all the same events fire.

When a [media element<sup>p326</sup>](#) has a [current media controller<sup>p360</sup>](#), the user agent's user interface for pausing and unpauseing playback, for seeking, for changing the rate of playback, for fast-forwarding or rewinding, and for muting or changing the volume of audio of the entire group must be implemented in terms of the [MediaController<sup>p358</sup>](#) API exposed on that [current media controller<sup>p360</sup>](#). When a [media element<sup>p326</sup>](#) has a [current media controller<sup>p360</sup>](#), and all the [slaved media elements<sup>p360</sup>](#) of that [MediaController<sup>p358</sup>](#) are paused, the user agent should also unpause all the [slaved media elements<sup>p360</sup>](#) when the user invokes a user agent interface control for beginning playback.

The "play" function in the user agent's interface must set the [playbackRate](#) attribute to the value of the [defaultPlaybackRate](#) attribute before invoking the [play\(\)](#) method. When a [media element<sup>p326</sup>](#) has a [current media controller<sup>p360</sup>](#), the attributes and method with those names on that [MediaController<sup>p358</sup>](#) object must be used. Otherwise, the attributes and method with those names on the [media element<sup>p326</sup>](#) itself must be used.

Features such as fast-forward or rewind must be implemented by only changing the [playbackRate](#) attribute (and not the [defaultPlaybackRate](#) attribute). Again, when a [media element<sup>p326</sup>](#) has a [current media controller<sup>p360</sup>](#), the attributes with those names on that [MediaController<sup>p358</sup>](#) object must be used; otherwise, the attributes with those names on the [media element<sup>p326</sup>](#) itself must be used.

When a [media element](#)<sup>p326</sup> has a [current media controller](#)<sup>p360</sup>, seeking must be implemented in terms of the [currentTime](#)<sup>p361</sup> attribute on that [MediaController](#)<sup>p358</sup> object. Otherwise, the user agent must directly [seek](#)<sup>p351</sup> to the requested position in the [media element](#)<sup>p326</sup>'s [media timeline](#)<sup>p341</sup>. For media resources where seeking to an arbitrary position would be slow, user agents are encouraged to use the [approximate-for-speed](#) flag when seeking in response to the user manipulating an approximate position interface such as a seek bar.

When a [media element](#)<sup>p326</sup> has a [current media controller](#)<sup>p360</sup>, user agents may additionally provide the user with controls that directly manipulate an individual [media element](#)<sup>p326</sup> without affecting the [MediaController](#)<sup>p358</sup>, but such features are considered relatively advanced and unlikely to be useful to most users.

The [activation behaviour](#)<sup>p725</sup> of a [media element](#)<sup>p326</sup> that is [exposing a user interface to the user](#)<sup>p382</sup> must be to run the following steps:

1. If the [media element](#)<sup>p326</sup> has a [current media controller](#)<sup>p360</sup>, and that [current media controller](#)<sup>p360</sup> is a [restrained media controller](#)<sup>p362</sup>, then invoke the [play\(\)](#)<sup>p361</sup> method of the [MediaController](#)<sup>p358</sup> and abort these steps.
2. If the [media element](#)<sup>p326</sup> has a [current media controller](#)<sup>p360</sup>, and that [current media controller](#)<sup>p360</sup> is a [paused media controller](#)<sup>p361</sup>, all of the [MediaController](#)<sup>p358</sup>'s [slaved media elements](#)<sup>p360</sup> have [ended playback](#)<sup>p346</sup>, and the [media controller playback rate](#)<sup>p361</sup> is positive or zero, then [seek the media controller](#)<sup>p362</sup> to zero.
3. If the [media element](#)<sup>p326</sup> has a [current media controller](#)<sup>p360</sup>, and that [current media controller](#)<sup>p360</sup> is a [paused media controller](#)<sup>p361</sup>, then invoke the [unpause\(\)](#)<sup>p361</sup> method of the [MediaController](#)<sup>p358</sup> and abort these steps.
4. If the [media element](#)<sup>p326</sup> has a [current media controller](#)<sup>p360</sup>, then that [current media controller](#)<sup>p360</sup> is a [playing media controller](#)<sup>p361</sup>; invoke the [pause\(\)](#)<sup>p361</sup> method of the [MediaController](#)<sup>p358</sup> and abort these steps.
5. If the [media element](#)<sup>p326</sup>'s [paused](#)<sup>p346</sup> attribute is true, then invoke the [play\(\)](#)<sup>p347</sup> method on the [media element](#)<sup>p326</sup> and abort these steps.
6. Invoke the [pause\(\)](#)<sup>p348</sup> method on the [media element](#)<sup>p326</sup>.

For the purposes of listing chapters in the [media resource](#)<sup>p328</sup>, only [text tracks](#)<sup>p365</sup> in the [media element](#)<sup>p326</sup>'s [list of text tracks](#)<sup>p365</sup> that are [showing](#)<sup>p367</sup> and whose [text track kind](#)<sup>p366</sup> is [chapters](#)<sup>p366</sup> should be used. Such tracks must be interpreted according to the [rules for constructing the chapter tree from a text track](#)<sup>p379</sup>. When seeking in response to a user manipulating a chapter selection interface, user agents should not use the [approximate-for-speed](#) flag.

The [controls](#) IDL attribute must [reflect](#)<sup>p88</sup> the content attribute of the same name.

#### Note

##### `media . volumep383 [= value]`

Returns the current playback volume, as a number in the range 0.0 to 1.0, where 0.0 is the quietest and 1.0 the loudest.

Can be set, to change the volume.

Throws an [IndexSizeError](#)<sup>p50</sup> exception if the new value is not in the range 0.0 .. 1.0.

##### `media . mutedp383 [= value]`

Returns true if audio is muted, overriding the [volume](#)<sup>p383</sup> attribute, and false if the [volume](#)<sup>p383</sup> attribute is being honored.

Can be set, to change whether the audio is muted or not.

A [media element](#)<sup>p326</sup> has a [playback volume](#), which is a fraction in the range 0.0 (silent) to 1.0 (loudest). Initially, the volume should be 1.0, but user agents may remember the last set value across sessions, on a per-site basis or otherwise, so the volume may start at other values.

The [volume](#) IDL attribute must return the [playback volume](#)<sup>p383</sup> of any audio portions of the [media element](#)<sup>p326</sup>. On setting, if the new value is in the range 0.0 to 1.0 inclusive, the [media element](#)<sup>p326</sup>'s [playback volume](#)<sup>p383</sup> must be set to the new value. If the new value is outside the range 0.0 to 1.0 inclusive, then, on setting, an [IndexSizeError](#)<sup>p50</sup> exception must be thrown instead.

A [media element](#)<sup>p326</sup> can also be [muted](#). If anything is muting the element, then it is muted. (For example, when the [direction of playback](#)<sup>p348</sup> is backwards, the element is muted.)

The [muted](#) IDL attribute must return the value to which it was last set. When a [media element](#)<sup>p326</sup> is created, if the element has a [muted](#)<sup>p384</sup> content attribute specified, then the [muted](#)<sup>p383</sup> IDL attribute should be set to true; otherwise, the user agents may set the value to the user's preferred value

(e.g. remembering the last set value across sessions, on a per-site basis or otherwise). While the `muted`<sup>p383</sup> IDL attribute is set to true, the `media element`<sup>p326</sup> must be `muted`<sup>p383</sup>.

Whenever either of the values that would be returned by the `volume`<sup>p383</sup> and `muted`<sup>p383</sup> IDL attributes change, the user agent must [queue a task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> named `volumechange`<sup>p387</sup> at the `media element`<sup>p326</sup>.

An element's **effective media volume** is determined as follows:

1. If the user has indicated that the user agent is to override the volume of the element, then the element's `effective media volume`<sup>p384</sup> is the volume desired by the user. Abort these steps.
2. If the element's audio output is `muted`<sup>p383</sup>, the element's `effective media volume`<sup>p384</sup> is zero. Abort these steps.
3. If the element has a `current media controller`<sup>p360</sup> and that `MediaController`<sup>p358</sup> object's `media controller mute override`<sup>p362</sup> is true, the element's `effective media volume`<sup>p384</sup> is zero. Abort these steps.
4. Let `volume` be the `playback volume`<sup>p383</sup> of the audio portions of the `media element`<sup>p326</sup>, in range 0.0 (silent) to 1.0 (loudest).
5. If the element has a `current media controller`<sup>p360</sup>, multiply `volume` by that `MediaController`<sup>p358</sup> object's `media controller volume multiplier`<sup>p362</sup>. (The `media controller volume multiplier`<sup>p362</sup> is in the range 0.0 to 1.0, so this can only reduce the value.)
6. The element's `effective media volume`<sup>p384</sup> is `volume`, interpreted relative to the range 0.0 to 1.0, with 0.0 being silent, and 1.0 being the loudest setting, values in between increasing in loudness. The range need not be linear. The loudest setting may be lower than the system's loudest possible setting; for example the user could have set a maximum volume.

The `muted` content attribute on `media elements`<sup>p326</sup> is a [boolean attribute](#)<sup>p59</sup> that controls the default state of the audio output of the `media resource`<sup>p328</sup>, potentially overriding user preferences.

The `defaultMuted` IDL attribute must [reflect](#)<sup>p88</sup> the `muted`<sup>p384</sup> content attribute.

**Note** *This attribute has no dynamic effect (it only controls the default state of the element).*

**Example**

This video (an advertisement) autoplays, but to avoid annoying users, it does so without sound, and allows the user to turn the sound on.

```
<video src="adverts.cgi?kind=video" controls autoplay loop muted></video>
```

#### 4.8.14.14 Time ranges

Spec bugs: [18176](#)

Objects implementing the `TimeRanges`<sup>p384</sup> interface represent a list of ranges (periods) of time.

**IDL**

```
interface TimeRanges {
 readonly attribute unsigned long length;
 double start(unsigned long index);
 double end(unsigned long index);
};
```

**Note**

`media.length`<sup>p385</sup>

Returns the number of ranges in the object.

`time = media.start`<sup>p385</sup>(`index`)

Returns the time for the start of the range with the given index.

Throws an `IndexSizeError`<sup>p50</sup> exception if the index is out of range.

`time = media.end`<sup>p385</sup>(`index`)

Returns the time for the end of the range with the given index.

Throws an [IndexSizeError<sup>p50</sup>](#) exception if the index is out of range.

The **length** IDL attribute must return the number of ranges represented by the object.

The **start(index)** method must return the position of the start of the *index*th range represented by the object, in seconds measured from the start of the timeline that the object covers.

The **end(index)** method must return the position of the end of the *index*th range represented by the object, in seconds measured from the start of the timeline that the object covers.

These methods must throw [IndexSizeError<sup>p50</sup>](#) exceptions if called with an *index* argument greater than or equal to the number of ranges represented by the object.

When a [TimeRanges<sup>p384</sup>](#) object is said to be a **normalised TimeRanges object**, the ranges it represents must obey the following criteria:

- The start of a range must be greater than the end of all earlier ranges.
- The start of a range must be less than or equal to the end of that same range.

In other words, the ranges in such an object are ordered, don't overlap, and don't touch (adjacent ranges are folded into one bigger range). A range can be empty (referencing just a single moment in time), e.g. to indicate that only one frame is currently buffered in the case that the user agent has discarded the entire [media resource<sup>p328</sup>](#) except for the current frame, when a [media element<sup>p326</sup>](#) is paused.

Ranges in a [TimeRanges<sup>p384</sup>](#) object must be inclusive.

**Example** Thus, the end of a range would be equal to the start of a following adjacent (touching but not overlapping) range. Similarly, a range covering a whole timeline anchored at zero would have a start equal to zero and an end equal to the duration of the timeline.

The timelines used by the objects returned by the [buffered<sup>p340</sup>](#), [seekable<sup>p352</sup>](#) and [played<sup>p347</sup>](#) IDL attributes of [media elements<sup>p326</sup>](#) must be that element's [media timeline<sup>p341</sup>](#).

#### 4.8.14.15 The [TrackEvent<sup>p385</sup>](#) interface

**IDL**

```
[Constructor(DOMString type, optional TrackEventInit eventInitDict)]
interface TrackEvent : Event {
 readonly attribute (VideoTrack or AudioTrack or TextTrack)? track;
};

dictionary TrackEventInit : EventInit {
 (VideoTrack or AudioTrack or TextTrack)? track;
};
```

**Note** [event.track<sup>p385</sup>](#)

Returns the track object ([TextTrack<sup>p374</sup>](#), [AudioTrack<sup>p354</sup>](#), or [VideoTrack<sup>p354</sup>](#)) to which the event relates.

The **track** attribute must return the value it was initialised to. When the object is created, this attribute must be initialised to null. It represents the context information for the event.

#### 4.8.14.16 Event summary

*This section is non-normative.*

The following events fire on [media elements](#) as part of the processing model described above:

Event name	Interface	Fired when...	Preconditions
<code>loadstart</code>	<a href="#">Event</a>	The user agent begins looking for <a href="#">media data</a> , as part of the <a href="#">resource selection algorithm</a> .	<code>networkState</code> equals <a href="#">NETWORK_LOADING</a>
<code>progress</code>	<a href="#">Event</a>	The user agent is fetching <a href="#">media data</a> .	<code>networkState</code> equals <a href="#">NETWORK_LOADING</a>
<code>suspend</code>	<a href="#">Event</a>	The user agent is intentionally not currently fetching <a href="#">media data</a> .	<code>networkState</code> equals <a href="#">NETWORK_IDLE</a>
<code>abort</code>	<a href="#">Event</a>	The user agent stops fetching the <a href="#">media data</a> before it is completely downloaded, but not due to an error.	<code>error</code> is an object with the code <a href="#">MEDIA_ERR_ABORTED</a> . <code>networkState</code> equals either <a href="#">NETWORK_EMPTY</a> or <a href="#">NETWORK_IDLE</a> , depending on when the download was aborted.
<code>error</code>	<a href="#">Event</a>	An error occurs while fetching the <a href="#">media data</a> .	<code>error</code> is an object with the code <a href="#">MEDIA_ERR_NETWORK</a> or higher. <code>networkState</code> equals either <a href="#">NETWORK_EMPTY</a> or <a href="#">NETWORK_IDLE</a> , depending on when the download was aborted.
<code>emptied</code>	<a href="#">Event</a>	A <a href="#">media element</a> whose <code>networkState</code> was previously not in the <a href="#">NETWORK_EMPTY</a> state has just switched to that state (either because of a fatal error during load that's about to be reported, or because the <code>load()</code> method was invoked while the <a href="#">resource selection algorithm</a> was already running).	<code>networkState</code> is <a href="#">NETWORK_EMPTY</a> ; all the IDL attributes are in their initial states.
<code>stalled</code>	<a href="#">Event</a>	The user agent is trying to fetch <a href="#">media data</a> , but data is unexpectedly not forthcoming.	<code>networkState</code> is <a href="#">NETWORK_LOADING</a> .
<code>loadedmetadata</code>	<a href="#">Event</a>	The user agent has just determined the duration and dimensions of the <a href="#">media resource</a> and <a href="#">the text tracks are ready</a> .	<code>readyState</code> is newly equal to <a href="#">HAVE_METADATA</a> or greater for the first time.
<code>loadeddata</code>	<a href="#">Event</a>	The user agent can render the <a href="#">media data</a> at the <a href="#">current playback position</a> for the first time.	<code>readyState</code> newly increased to <a href="#">HAVE_CURRENT_DATA</a> or greater for the first time.
<code>canplay</code>	<a href="#">Event</a>	The user agent can resume playback of the <a href="#">media data</a> , but estimates that if playback were to be started now, the <a href="#">media resource</a> could not be rendered at the current playback rate up to its end without having to stop for further buffering of content.	<code>readyState</code> newly increased to <a href="#">HAVE_FUTURE_DATA</a> or greater.
<code>canplaythrough</code>	<a href="#">Event</a>	The user agent estimates that if playback were to be started now, the <a href="#">media resource</a> could be rendered at the current playback rate all the way to its end without having to stop for further buffering.	<code>readyState</code> is newly equal to <a href="#">HAVE_ENOUGH_DATA</a> .
<code>playing</code>	<a href="#">Event</a>	Playback is ready to start after having been paused or delayed due to lack of <a href="#">media data</a> .	<code>readyState</code> is newly equal to or greater than <a href="#">HAVE_FUTURE_DATA</a> and <code>paused</code> is false, or <code>paused</code> is newly false and <code>readyState</code> is equal to or greater than <a href="#">HAVE_FUTURE_DATA</a> . Even if this event fires, the element might still not be <a href="#">potentially playing</a> , e.g. if the element is <a href="#">blocked on its media controller</a> (e.g. because the <a href="#">current media controller</a> is paused, or another <a href="#">slaved media element</a> is stalled somehow, or because the <a href="#">media resource</a> has no data corresponding to the <a href="#">media controller position</a> , or the element is <a href="#">paused for user interaction</a> or <a href="#">paused for in-band content</a> ).
<code>waiting</code>	<a href="#">Event</a>	Playback has stopped because the next frame is not available, but the user agent expects that frame to become available in due course.	<code>readyState</code> is equal to or less than <a href="#">HAVE_CURRENT_DATA</a> , and <code>paused</code> is false. Either <code>seeking</code> is true, or the <a href="#">current playback position</a> is not contained in any of the ranges in <a href="#">buffered</a> . It is possible for playback to stop for other reasons without <code>paused</code> being false, but those reasons do not fire this event (and when those situations resolve, a separate <code>playing</code> event is not fired either): e.g. the element is newly <a href="#">blocked on its media controller</a> , or <a href="#">playback ended</a> , or playback <a href="#">stopped due to errors</a> , or the element has <a href="#">paused for user interaction</a> or <a href="#">paused for in-band content</a> .
<code>seeking</code>	<a href="#">Event</a>	The <code>seeking</code> IDL attribute changed to true, and the user agent has started seeking to a new position.	
<code>seeked</code>	<a href="#">Event</a>	The <code>seeking</code> IDL attribute changed to false after the <a href="#">current playback position</a> was changed.	
<code>ended</code>	<a href="#">Event</a>	Playback has stopped because the end of the <a href="#">media resource</a> was reached.	<code>currentTime</code> equals the end of the <a href="#">media resource</a> ; <code>ended</code> is true.

Event name	Interface	Fired when...	Preconditions
durationchange	Event <sup>p51</sup>	The <code>duration</code> <sup>p342</sup> attribute has just been updated.	
timeupdate	Event <sup>p51</sup>	The <code>current playback position</code> <sup>p342</sup> changed as part of normal playback or in an especially interesting way, for example discontinuously.	
play	Event <sup>p51</sup>	The element is no longer paused. Fired after the <code>play()</code> <sup>p347</sup> method has returned, or when the <code>autoplay</code> <sup>p345</sup> attribute has caused playback to begin.	<code>paused</code> <sup>p346</sup> is newly false.
pause	Event <sup>p51</sup>	The element has been paused. Fired after the <code>pause()</code> <sup>p348</sup> method has returned.	<code>paused</code> <sup>p346</sup> is newly true.
ratechange	Event <sup>p51</sup>	Either the <code>defaultPlaybackRate</code> <sup>p347</sup> or the <code>playbackRate</code> <sup>p347</sup> attribute has just been updated.	
resize	Event <sup>p51</sup>	One or both of the <code>videoWidth</code> <sup>p319</sup> and <code>videoHeight</code> <sup>p319</sup> attributes have just been updated.	Media element <sup>p326</sup> is a <code>video</code> <sup>p317</sup> element; <code>readyState</code> <sup>p345</sup> is not <code>HAVE NOTHING</code> <sup>p343</sup>
volumechange	Event <sup>p51</sup>	Either the <code>volume</code> <sup>p383</sup> attribute or the <code>muted</code> <sup>p383</sup> attribute has changed. Fired after the relevant attribute's setter has returned.	

The following events fire on `MediaController`<sup>p358</sup> objects:

Event name	Interface	Fired when...
emptied	Event <sup>p51</sup>	All the <code>slaved media elements</code> <sup>p360</sup> newly have <code>readyState</code> <sup>p345</sup> set to <code>HAVE NOTHING</code> <sup>p343</sup> or greater, or there are no longer any <code>slaved media elements</code> <sup>p360</sup> .
loadedmetadata	Event <sup>p51</sup>	All the <code>slaved media elements</code> <sup>p360</sup> newly have <code>readyState</code> <sup>p345</sup> set to <code>HAVE_METADATA</code> <sup>p343</sup> or greater.
loadeddata	Event <sup>p51</sup>	All the <code>slaved media elements</code> <sup>p360</sup> newly have <code>readyState</code> <sup>p345</sup> set to <code>HAVE_CURRENT_DATA</code> <sup>p343</sup> or greater.
canplay	Event <sup>p51</sup>	All the <code>slaved media elements</code> <sup>p360</sup> newly have <code>readyState</code> <sup>p345</sup> set to <code>HAVE_FUTURE_DATA</code> <sup>p343</sup> or greater.
canplaythrough	Event <sup>p51</sup>	All the <code>slaved media elements</code> <sup>p360</sup> newly have <code>readyState</code> <sup>p345</sup> set to <code>HAVE_ENOUGH_DATA</code> <sup>p344</sup> .
playing	Event <sup>p51</sup>	The <code>MediaController</code> <sup>p358</sup> is no longer a <code>blocked media controller</code> <sup>p362</sup> .
waiting	Event <sup>p51</sup>	The <code>MediaController</code> <sup>p358</sup> is now a <code>blocked media controller</code> <sup>p362</sup> .
ended	Event <sup>p51</sup>	All the <code>slaved media elements</code> <sup>p360</sup> have newly <code>ended playback</code> <sup>p346</sup> ; the <code>MediaController</code> <sup>p358</sup> has reached the end of all the <code>slaved media elements</code> <sup>p360</sup> .
durationchange	Event <sup>p51</sup>	The <code>duration</code> <sup>p361</sup> attribute has just been updated.
timeupdate	Event <sup>p51</sup>	The <code>media controller position</code> <sup>p362</sup> changed.
play	Event <sup>p51</sup>	The <code>paused</code> <sup>p361</sup> attribute is newly false.
pause	Event <sup>p51</sup>	The <code>paused</code> <sup>p361</sup> attribute is newly true.
ratechange	Event <sup>p51</sup>	Either the <code>defaultPlaybackRate</code> <sup>p361</sup> attribute or the <code>playbackRate</code> <sup>p361</sup> attribute has just been updated.
volumechange	Event <sup>p51</sup>	Either the <code>volume</code> <sup>p361</sup> attribute or the <code>muted</code> <sup>p362</sup> attribute has just been updated.

The following events fire on `AudioTrackList`<sup>p354</sup>, `VideoTrackList`<sup>p354</sup>, and `TextTrackList`<sup>p373</sup> objects:

Event name	Interface	Fired when...
change	Event <sup>p51</sup>	One or more tracks in the track list have been enabled or disabled.
addtrack	TrackEvent <sup>p385</sup>	A track has been added to the track list.
removetrack	TrackEvent <sup>p385</sup>	A track has been removed from the track list.

The following event fires on `TextTrack`<sup>p374</sup> objects and `track`<sup>p324</sup> elements:

Event name	Interface	Fired when...
cuechange	Event <sup>p51</sup>	One or more cues in the track have become active or stopped being active.

The following events fire on `TextTrackCue`<sup>p378</sup> objects:

Event name	Interface	Fired when...
enter	Event <sup>p51</sup>	The cue has become active.
exit	Event <sup>p51</sup>	The cue has stopped being active.

#### 4.8.14.17 Security and privacy considerations

The main security and privacy implications of the [video<sup>p317</sup>](#) and [audio<sup>p321</sup>](#) elements come from the ability to embed media cross-origin. There are two directions that threats can flow: from hostile content to a victim page, and from a hostile page to victim content.

If a victim page embeds hostile content, the threat is that the content might contain scripted code that attempts to interact with the [Document<sup>p102</sup>](#) that embeds the content. To avoid this, user agents must ensure that there is no access from the content to the embedding page. In the case of media content that uses DOM concepts, the embedded content must be treated as if it was in its own unrelated [top-level browsing context<sup>p763</sup>](#).

**Example** For instance, if an SVG animation was embedded in a [video<sup>p317</sup>](#) element, the user agent would not give it access to the DOM of the outer page. From the perspective of scripts in the SVG resource, the SVG file would appear to be in a lone top-level browsing context with no parent.

If a hostile page embeds victim content, the threat is that the embedding page could obtain information from the content that it would not otherwise have access to. The API does expose some information: the existence of the media, its type, its duration, its size, and the performance characteristics of its host. Such information is already potentially problematic, but in practice the same information can more or less be obtained using the [img<sup>p272</sup>](#) element, and so it has been deemed acceptable.

However, significantly more sensitive information could be obtained if the user agent further exposes metadata within the content such as subtitles or chapter titles. Such information is therefore only exposed if the video resource passes a CORS [resource sharing check<sup>p49</sup>](#). The [crossorigin<sup>p329</sup>](#) attribute allows authors to control how this check is performed. [\[FETCH\]<sup>p1150</sup>](#)

**Example** Without this restriction, an attacker could trick a user running within a corporate network into visiting a site that attempts to load a video from a previously leaked location on the corporation's intranet. If such a video included confidential plans for a new product, then being able to read the subtitles would present a serious confidentiality breach.

#### 4.8.14.18 Best practices for authors using media elements

*This section is non-normative.*

Playing audio and video resources on small devices such as set-top boxes or mobile phones is often constrained by limited hardware resources in the device. For example, a device might only support three simultaneous videos. For this reason, it is a good practice to release resources held by [media elements<sup>p326</sup>](#) when they are done playing, either by being very careful about removing all references to the element and allowing it to be garbage collected, or, even better, by removing the element's [src<sup>p329</sup>](#) attribute and any [source<sup>p322</sup>](#) element descendants, and invoking the element's [load\(\)<sup>p331</sup>](#) method.

Similarly, when the playback rate is not exactly 1.0, hardware, software, or format limitations can cause video frames to be dropped and audio to be choppy or muted.

#### 4.8.14.19 Best practices for implementors of media elements

*This section is non-normative.*

How accurately various aspects of the [media element<sup>p326</sup>](#) API are implemented is considered a quality-of-implementation issue.

For example, when implementing the [buffered<sup>p340</sup>](#) attribute, how precise an implementation reports the ranges that have been buffered depends on how carefully the user agent inspects the data. Since the API reports ranges as times, but the data is obtained in byte streams, a user agent receiving a variable-bit-rate stream might only be able to determine precise times by actually decoding all of the data. User agents aren't required to do this, however; they can instead return estimates (e.g. based on the average bit rate seen so far) which get revised as more information becomes available.

As a general rule, user agents are urged to be conservative rather than optimistic. For example, it would be bad to report that everything had been buffered when it had not.

Another quality-of-implementation issue would be playing a video backwards when the codec is designed only for forward playback (e.g. there aren't many key frames, and they are far apart, and the intervening frames only have deltas from the previous frame). User agents could do a poor

job, e.g. only showing key frames; however, better implementations would do more work and thus do a better job, e.g. actually decoding parts of the video forwards, storing the complete frames, and then playing the frames backwards.

Similarly, while implementations are allowed to drop buffered data at any time (there is no requirement that a user agent keep all the media data obtained for the lifetime of the media element), it is again a quality of implementation issue: user agents with sufficient resources to keep all the data around are encouraged to do so, as this allows for a better user experience. For example, if the user is watching a live stream, a user agent could allow the user only to view the live video; however, a better user agent would buffer everything and allow the user to seek through the earlier material, pause it, play it forwards and backwards, etc.

When multiple tracks are synchronised with a [MediaController](#)<sup>p358</sup>, it is possible for scripts to add and remove media elements from the [MediaController](#)<sup>p358</sup>'s list of [slaved media elements](#)<sup>p360</sup>, even while these tracks are playing. How smoothly the media plays back in such situations is another quality-of-implementation issue.

When a [media element](#)<sup>p326</sup> that is paused is [removed from a document](#)<sup>p42</sup> and not reinserted before the next time the [event loop](#)<sup>p834</sup> reaches [step 1](#)<sup>p836</sup>, implementations that are resource constrained are encouraged to take that opportunity to release all hardware resources (like video planes, networking resources, and data buffers) used by the [media element](#)<sup>p326</sup>. (User agents still have to keep track of the playback position and so forth, though, in case playback is later restarted.)

#### 4.8.15 The `map` element

**Categories**<sup>p113</sup>:

[Flow content](#)<sup>p115</sup>.  
[Phrasing content](#)<sup>p116</sup>.  
[Palpable content](#)<sup>p117</sup>.

**Contexts in which this element can be used**<sup>p113</sup>:

Where [phrasing content](#)<sup>p116</sup> is expected.

**Content model**<sup>p113</sup>:

[Transparent](#)<sup>p117</sup>.

**Tag omission in text/html**<sup>p113</sup>:

Neither tag is omissible.

**Content attributes**<sup>p113</sup>:

[Global attributes](#)<sup>p120</sup>  
[name](#)<sup>p389</sup> — Name of [image map](#)<sup>p393</sup> to reference from the [usemap](#)<sup>p393</sup> attribute

**DOM interface**<sup>p113</sup>:

```
IDL interface HTMLMapElement : HTMLElement {
 attribute DOMString name;
 readonly attribute HTMLCollection areas;
 readonly attribute HTMLCollection images;
};
```

The [map](#)<sup>p389</sup> element, in conjunction with an [img](#)<sup>b272</sup> element and any [area](#)<sup>p390</sup> element descendants, defines an [image map](#)<sup>p393</sup>. The element [represents](#)<sup>p111</sup> its children.

The [name](#) attribute gives the map a name so that it can be referenced. The attribute must be present and must have a non-empty value with no [space characters](#)<sup>b58</sup>. The value of the [name](#)<sup>p389</sup> attribute must not be a [compatibility-caseless](#)<sup>p58</sup> match for the value of the [name](#)<sup>p389</sup> attribute of another [map](#)<sup>p389</sup> element in the same document. If the [id](#)<sup>b122</sup> attribute is also specified, both attributes must have the same value.

Note

`map . areas`<sup>p390</sup>

Returns an [HTMLCollection](#)<sup>p51</sup> of the [area](#)<sup>p390</sup> elements in the [map](#)<sup>p389</sup>.

`map . images`<sup>p390</sup>

Returns an [HTMLCollection](#)<sup>p51</sup> of the [img](#)<sup>p272</sup> and [object](#)<sup>p310</sup> elements that use the [map](#)<sup>p389</sup>.

The `areas` attribute must return an [HTMLCollection](#)<sup>p51</sup> rooted at the [map](#)<sup>p389</sup> element, whose filter matches only [area](#)<sup>p390</sup> elements.

The `images` attribute must return an [HTMLCollection](#)<sup>p51</sup> rooted at the [Document](#)<sup>p102</sup> node, whose filter matches only [img](#)<sup>p272</sup> and [object](#)<sup>p310</sup> elements that are associated with this [map](#)<sup>p389</sup> element according to the [image map](#)<sup>p393</sup> processing model.

The IDL attribute `name` must [reflect](#)<sup>p88</sup> the content attribute of the same name.

### Example

Image maps can be defined in conjunction with other content on the page, to ease maintenance. This example is of a page with an image map at the top of the page and a corresponding set of text links at the bottom.

```
<!DOCTYPE HTML>
<TITLE>Babies™: Toys</TITLE>
<HEADER>
 <H1>Toys</H1>
 <IMG SRC="/images/menu.gif"
 ALT="Babies™ navigation menu. Select a department to go to its page."
 USEMAP="#NAV">
</HEADER>
...
<FOOTER>
 <MAP NAME="NAV">
 <P>
 Clothes
 <AREA ALT="Clothes" COORDS="0,0,100,50" HREF="/clothes/"> |
 Toys
 <AREA ALT="Toys" COORDS="100,0,200,50" HREF="/toys/"> |
 Food
 <AREA ALT="Food" COORDS="200,0,300,50" HREF="/food/"> |
 Books
 <AREA ALT="Books" COORDS="300,0,400,50" HREF="/books/">
 </P>
 </MAP>
</FOOTER>
```

## 4.8.16 The `area` element

Spec bugs: [21787](#), [25337](#),  
[13449](#)

Categories<sup>p113</sup>:

[Flow content](#)<sup>p115</sup>.

[Phrasing content](#)<sup>p116</sup>.

Contexts in which this element can be used<sup>p113</sup>:

Where [phrasing content](#)<sup>p116</sup> is expected, but only if there is a [map](#)<sup>p389</sup> element ancestor or a [template](#)<sup>p604</sup> element ancestor.

Content model<sup>p113</sup>:

[Nothing](#)<sup>p114</sup>.

Tag omission in text/html<sup>p113</sup>:

No [end tag](#)<sup>p944</sup>.

## Content attributes<sup>b113</sup>:

### Global attributes<sup>b120</sup>

alt<sup>p391</sup> — Replacement text for use when images are not available  
coords<sup>p392</sup> — Coordinates for the shape to be created in an image map<sup>p393</sup>  
shape<sup>p391</sup> — The kind of shape to be created in an image map<sup>p393</sup>  
href<sup>p245</sup> — Address of the hyperlink<sup>p245</sup>  
target<sup>p245</sup> — Browsing context<sup>p762</sup> for hyperlink<sup>p245</sup> navigation<sup>p791</sup>  
download<sup>p246</sup> — Whether to download the resource instead of navigating to it, and its file name if so  
ping<sup>p246</sup> — URLs<sup>p48</sup> to ping  
rel<sup>p246</sup> — Relationship between the document containing the hyperlink and the destination resource  
hreflang<sup>p246</sup> — Language of the linked resource  
type<sup>p246</sup> — Hint for the type of the referenced resource

## DOM interface<sup>b113</sup>:

```
IDL
interface HTMLAreaElement : HTMLElement {
 attribute DOMString alt;
 attribute DOMString coords;
 attribute DOMString shape;
 attribute DOMString target;
 attribute DOMString download;
 [PutForwards=value] attribute DOMSettableTokenList ping;
 attribute DOMString rel;
 readonly attribute DOMTokenList relList;
 attribute DOMString hreflang;
 attribute DOMString type;

 // also has obsolete members
};

HTMLAreaElement implements URLUtils;
```

The area<sup>p390</sup> element represents<sup>b111</sup> either a hyperlink with some text and a corresponding area on an image map<sup>p393</sup>, or a dead area on an image map.

An area<sup>p390</sup> element with a parent node must have a map<sup>p389</sup> element ancestor or a template<sup>p604</sup> element ancestor.

If the area<sup>p390</sup> element has an href<sup>p245</sup> attribute, then the area<sup>p390</sup> element represents a hyperlink<sup>p245</sup>. In this case, the alt attribute must be present. It specifies the text of the hyperlink. Its value must be text that, when presented with the texts specified for the other hyperlinks of the image map<sup>p393</sup>, and with the alternative text of the image, but without the image itself, provides the user with the same kind of choice as the hyperlink would when used without its text but with its shape applied to the image. The alt<sup>p391</sup> attribute may be left blank if there is another area<sup>p390</sup> element in the same image map<sup>p393</sup> that points to the same resource and has a non-blank alt<sup>p391</sup> attribute.

If the area<sup>p390</sup> element has no href<sup>p245</sup> attribute, then the area represented by the element cannot be selected, and the alt<sup>p391</sup> attribute must be omitted.

In both cases, the shape<sup>p391</sup> and coords<sup>p392</sup> attributes specify the area.

The shape attribute is an enumerated attribute<sup>b60</sup>. The following table lists the keywords defined for this attribute. The states given in the first cell of the rows with keywords give the states to which those keywords map. Some of the keywords are non-conforming, as noted in the last column.

State	Keywords	Notes
Circle state <sup>b392</sup>	<u>circle</u>	
	<u>circ</u>	Non-conforming
Default state <sup>p392</sup>	<u>default</u>	
Polygon state <sup>p392</sup>	<u>poly</u>	
	<u>polygon</u>	Non-conforming
Rectangle state <sup>p392</sup>	<u>rect</u>	

State	Keywords	Notes
	rectangle	Non-conforming

The attribute may be omitted. The [missing value default<sup>p60</sup>](#) is the [rectangle<sup>p392</sup>](#) state.

The [coords](#) attribute must, if specified, contain a [valid list of integers<sup>p64</sup>](#). This attribute gives the coordinates for the shape described by the [shape<sup>p391</sup>](#) attribute. The processing for this attribute is described as part of the [image map<sup>p393</sup>](#) processing model.

In the [circle state](#), [area<sup>p390</sup>](#) elements must have a [coords<sup>p392</sup>](#) attribute present, with three integers, the last of which must be non-negative. The first integer must be the distance in CSS pixels from the left edge of the image to the center of the circle, the second integer must be the distance in CSS pixels from the top edge of the image to the center of the circle, and the third integer must be the radius of the circle, again in CSS pixels.

In the [default state](#) state, [area<sup>p390</sup>](#) elements must not have a [coords<sup>p392</sup>](#) attribute. (The area is the whole image.)

In the [polygon state](#), [area<sup>p390</sup>](#) elements must have a [coords<sup>p392</sup>](#) attribute with at least six integers, and the number of integers must be even. Each pair of integers must represent a coordinate given as the distances from the left and the top of the image in CSS pixels respectively, and all the coordinates together must represent the points of the polygon, in order.

In the [rectangle state](#), [area<sup>p390</sup>](#) elements must have a [coords<sup>p392</sup>](#) attribute with exactly four integers, the first of which must be less than the third, and the second of which must be less than the fourth. The four points must represent, respectively, the distance from the left edge of the image to the left side of the rectangle, the distance from the top edge to the top side, the distance from the left edge to the right side, and the distance from the top edge to the bottom side, all in CSS pixels.

When user agents allow users to [follow hyperlinks<sup>p246</sup>](#) or [download hyperlinks<sup>p247</sup>](#) created using the [area<sup>p390</sup>](#) element, as described in the next section, the [href<sup>p245</sup>](#), [target<sup>p245</sup>](#), [download<sup>p246</sup>](#), and [ping<sup>p246</sup>](#) attributes decide how the link is followed. The [rel<sup>p246</sup>](#), [hreflang<sup>p246</sup>](#), and [type<sup>p246</sup>](#) attributes may be used to indicate to the user the likely nature of the target resource before the user follows the link.

The [target<sup>p245</sup>](#), [download<sup>p246</sup>](#), [ping<sup>p246</sup>](#), [rel<sup>p246</sup>](#), [hreflang<sup>p246</sup>](#), and [type<sup>p246</sup>](#) attributes must be omitted if the [href<sup>p245</sup>](#) attribute is not present.

If the [itemprop<sup>p692</sup>](#) attribute is specified on an [area<sup>p390</sup>](#) element, then the [href<sup>p245</sup>](#) attribute must also be specified.

The [activation behaviour<sup>p725</sup>](#) of [area<sup>p390</sup>](#) elements is to run the following steps:

1. If the [area<sup>p390</sup>](#) element's [node document](#) is not [fully active<sup>p763</sup>](#), then abort these steps.
2. If the [area<sup>p390</sup>](#) element has a [download<sup>p246</sup>](#) attribute and the algorithm is not [allowed to show a popup<sup>p766</sup>](#); or, if the user has not indicated a specific [browsing context<sup>p762</sup>](#) for following the link, and the element's [target<sup>p245</sup>](#) attribute is present, and applying [the rules for choosing a browsing context given a browsing context name<sup>p767</sup>](#), using the value of the [target<sup>p245</sup>](#) attribute as the browsing context name, would result in there not being a chosen browsing context, then run these substeps:
  1. If there is an [entry settings object<sup>p831</sup>](#), throw an [InvalidAccessError<sup>p50</sup>](#) exception.
  2. Abort these steps without following the hyperlink.
3. Otherwise, the user agent must [follow the hyperlink<sup>p246</sup>](#) or [download the hyperlink<sup>p247</sup>](#) created by the [area<sup>p390</sup>](#) element, if any, and as determined by the [download<sup>p246</sup>](#) attribute and any expressed user preference.

The IDL attributes [alt](#), [coords](#), [target](#), [download](#), [ping](#), [rel](#), [hreflang](#), and [type](#), each must [reflect<sup>p88</sup>](#) the respective content attributes of the same name.

The IDL attribute [shape](#) must [reflect<sup>p88</sup>](#) the [shape<sup>p391</sup>](#) content attribute.

The IDL attribute [relList](#) must [reflect<sup>p88</sup>](#) the [rel<sup>p246</sup>](#) content attribute.

The [area<sup>p390</sup>](#) element also supports the [URLUtils<sup>p48</sup>](#) interface. [\[URL\]<sup>p1153</sup>](#)

When the element is created, and whenever the element's [href<sup>p245</sup>](#) content attribute is set, changed, or removed, the user agent must invoke the element's [URLUtils<sup>p48</sup>](#) interface's [set the input<sup>p48</sup>](#) algorithm with the value of the [href<sup>p245</sup>](#) content attribute, if any, or the null value otherwise, as the given value.

The element's [URLUtils<sup>p48</sup>](#) interface's [get the base<sup>p48</sup>](#) algorithm must simply return [the element's base URL<sup>p83</sup>](#).

The element's [URLUtils](#)<sup>p48</sup> interface's [query encoding](#)<sup>p48</sup> is the [document's character encoding](#)<sup>p51</sup>.

When the element's [URLUtils](#)<sup>p48</sup> interface invokes its [update steps](#)<sup>p48</sup> with a string *value*, the user agent must set the element's [href](#)<sup>p245</sup> content attribute to the string *value*.

## 4.8.17 Image maps

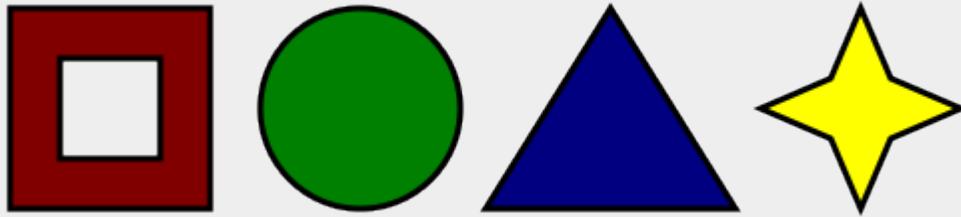

### 4.8.17.1 Authoring

An **image map** allows geometric areas on an image to be associated with [hyperlinks](#)<sup>p245</sup>.

An image, in the form of an [img](#)<sup>p272</sup> element or an [object](#)<sup>p310</sup> element representing an image, may be associated with an image map (in the form of a [map](#)<sup>p389</sup> element) by specifying a [usemap](#) attribute on the [img](#)<sup>p272</sup> or [object](#)<sup>p310</sup> element. The [usemap](#)<sup>p393</sup> attribute, if specified, must be a [valid hash-name reference](#)<sup>p81</sup> to a [map](#)<sup>p389</sup> element.

#### Example

Consider an image that looks as follows:

If we wanted just the coloured areas to be clickable, we could do it as follows:

```
<p>
 Please select a shape:

 <map name="shapes">
 <area shape=rect coords="50,50,100,100"> <!-- the hole in the red box -->
 <area shape=rect coords="25,25,125,125" href="red.html" alt="Red box.">
 <area shape=circle coords="200,75,50" href="green.html" alt="Green circle.">
 <area shape=poly coords="325,25,262,125,388,125" href="blue.html" alt="Blue triangle.">
 <area shape=poly coords="450,25,435,60,400,75,435,90,450,125,465,90,500,75,465,60"
 href="yellow.html" alt="Yellow star.">
 </map>
</p>
```

### 4.8.17.2 Processing model

If an [img](#)<sup>p272</sup> element or an [object](#)<sup>p310</sup> element representing an image has a [usemap](#)<sup>p393</sup> attribute specified, user agents must process it as follows:

1. Parse the attribute's value using the [rules for parsing a hash-name reference](#)<sup>p81</sup> to a [map](#)<sup>p389</sup> element, with the element's [node document](#) as the context node. This will return either an element (the *map*) or null.
2. If that returned null, then abort these steps. The image is not associated with an image map after all.
3. Otherwise, the user agent must collect all the [area](#)<sup>p390</sup> elements that are descendants of the *map*. Let those be the *areas*.

Having obtained the list of `area`<sup>p390</sup> elements that form the image map (the `areas`), interactive user agents must process the list in one of two ways.

If the user agent intends to show the text that the `img`<sup>p272</sup> element represents, then it must use the following steps.

**Note** In user agents that do not support images, or that have images disabled, `object`<sup>p310</sup> elements cannot represent images, and thus this section never applies (the `fallback content`<sup>p116</sup> is shown instead). The following steps therefore only apply to `img`<sup>p272</sup> elements.

1. Remove all the `area`<sup>p390</sup> elements in `areas` that have no `href`<sup>p245</sup> attribute.
2. Remove all the `area`<sup>p390</sup> elements in `areas` that have no `alt`<sup>p391</sup> attribute, or whose `alt`<sup>p391</sup> attribute's value is the empty string, if there is another `area`<sup>p390</sup> element in `areas` with the same value in the `href`<sup>p245</sup> attribute and with a non-empty `alt`<sup>p391</sup> attribute.
3. Each remaining `area`<sup>p390</sup> element in `areas` represents a `hyperlink`<sup>p245</sup>. Those hyperlinks should all be made available to the user in a manner associated with the text of the `img`<sup>p272</sup>.

In this context, user agents may represent `area`<sup>p390</sup> and `img`<sup>p272</sup> elements with no specified `alt` attributes, or whose `alt` attributes are the empty string or some other non-visible text, in a user-agent-defined fashion intended to indicate the lack of suitable author-provided text.

If the user agent intends to show the image and allow interaction with the image to select hyperlinks, then the image must be associated with a set of layered shapes, taken from the `area`<sup>p390</sup> elements in `areas`, in reverse `tree order`<sup>p42</sup> (so the last specified `area`<sup>p390</sup> element in the `map` is the bottom-most shape, and the first element in the `map`, in `tree order`<sup>p42</sup>, is the top-most shape).

Each `area`<sup>p390</sup> element in `areas` must be processed as follows to obtain a shape to layer onto the image:

1. Find the state that the element's `shape`<sup>p391</sup> attribute represents.
2. Use the [rules for parsing a list of integers](#)<sup>p64</sup> to parse the element's `coords`<sup>p392</sup> attribute, if it is present, and let the result be the `coords` list. If the attribute is absent, let the `coords` list be the empty list.
3. If the number of items in the `coords` list is less than the minimum number given for the `area`<sup>p390</sup> element's current state, as per the following table, then the shape is empty; abort these steps.

State	Minimum number of items
<a href="#">Circle state</a> <sup>p392</sup>	3
<a href="#">Default state</a> <sup>p392</sup>	0
<a href="#">Polygon state</a> <sup>p392</sup>	6
<a href="#">Rectangle state</a> <sup>p392</sup>	4

4. Check for excess items in the `coords` list as per the entry in the following list corresponding to the `shape`<sup>p391</sup> attribute's state:

↪ [Circle state](#)<sup>p392</sup>

Drop any items in the list beyond the third.

↪ [Default state](#)<sup>p392</sup>

Drop all items in the list.

↪ [Polygon state](#)<sup>p392</sup>

Drop the last item if there's an odd number of items.

↪ [Rectangle state](#)<sup>p392</sup>

Drop any items in the list beyond the fourth.

5. If the `shape`<sup>p391</sup> attribute represents the [rectangle state](#)<sup>p392</sup>, and the first number in the list is numerically less than the third number in the list, then swap those two numbers around.
6. If the `shape`<sup>p391</sup> attribute represents the [rectangle state](#)<sup>p392</sup>, and the second number in the list is numerically greater than the fourth number in the list, then swap those two numbers around.
7. If the `shape`<sup>p391</sup> attribute represents the [circle state](#)<sup>p392</sup>, and the third number in the list is less than or equal to zero, then the shape is empty; abort these steps.
8. Now, the shape represented by the element is the one described for the entry in the list below corresponding to the state of the `shape`<sup>p391</sup> attribute:

↪ [Circle state<sup>p392</sup>](#)

Let  $x$  be the first number in *coords*,  $y$  be the second number, and  $r$  be the third number.

The shape is a circle whose center is  $x$  CSS pixels from the left edge of the image and  $y$  CSS pixels from the top edge of the image, and whose radius is  $r$  pixels.

↪ [Default state<sup>p392</sup>](#)

The shape is a rectangle that exactly covers the entire image.

↪ [Polygon state<sup>p392</sup>](#)

Let  $x_i$  be the  $(2i)$ th entry in *coords*, and  $y_i$  be the  $(2i+1)$ th entry in *coords* (the first entry in *coords* being the one with index 0).

Let the *coordinates* be  $(x_i, y_i)$ , interpreted in CSS pixels measured from the top left of the image, for all integer values of  $i$  from 0 to  $(N/2)-1$ , where  $N$  is the number of items in *coords*.

The shape is a polygon whose vertices are given by the *coordinates*, and whose interior is established using the even-odd rule. [\[GRAPHICS\]<sup>p1150</sup>](#)

↪ [Rectangle state<sup>p392</sup>](#)

Let  $x_1$  be the first number in *coords*,  $y_1$  be the second number,  $x_2$  be the third number, and  $y_2$  be the fourth number.

The shape is a rectangle whose top-left corner is given by the coordinate  $(x_1, y_1)$  and whose bottom right corner is given by the coordinate  $(x_2, y_2)$ , those coordinates being interpreted as CSS pixels from the top left corner of the image.

For historical reasons, the coordinates must be interpreted relative to the *displayed* image after any stretching caused by the CSS 'width' and 'height' properties (or, for non-CSS browsers, the image element's *width* and *height* attributes — CSS browsers map those attributes to the aforementioned CSS properties).

**Note** *Browser zoom features and transforms applied using CSS or SVG do not affect the coordinates.*

Pointing device interaction with an image associated with a set of layered shapes per the above algorithm must result in the relevant user interaction events being first fired to the top-most shape covering the point that the pointing device indicated, if any, or to the image element itself, if there is no shape covering that point. User agents may also allow individual *area<sup>p390</sup>* elements representing [hyperlinks<sup>p245</sup>](#) to be selected and activated (e.g. using a keyboard).

**Note** *Because a *map<sup>p389</sup>* element (and its *area<sup>p390</sup>* elements) can be associated with multiple *img<sup>p272</sup>* and *object<sup>p310</sup>* elements, it is possible for an *area<sup>p390</sup>* element to correspond to multiple [focusable areas<sup>p726</sup>](#) of the document.*

Image maps are [live<sup>p43</sup>](#); if the DOM is mutated, then the user agent must act as if it had rerun the algorithms for image maps.

#### 4.8.18 MathML

The *math* element from the [MathML namespace<sup>p101</sup>](#) falls into the [embedded content<sup>p116</sup>](#), [phrasing content<sup>p116</sup>](#), and [flow content<sup>p11</sup>](#) for the purposes of the content models in this specification.

This specification refers to several specific MathML elements, in particular: [annotation-xml](#), [merror](#), [mi](#), [mn](#), [mo](#), [ms](#), and [mte](#)

When the MathML [annotation-xml<sup>p395</sup>](#) element contains elements from the [HTML namespace<sup>p101</sup>](#), such elements must all be [\[MATHML\]<sup>p1151</sup>](#)

When the MathML token elements ([mi<sup>p395</sup>](#), [mo<sup>p395</sup>](#), [mn<sup>p395</sup>](#), [ms<sup>p395</sup>](#), and [mtext<sup>p395</sup>](#)) are descendants of HTML elements, they may contain [phrasing content<sup>p116</sup>](#) elements from the [HTML namespace<sup>p101</sup>](#). [\[MATHML\]<sup>p1151</sup>](#)

User agents must handle text other than [inter-element whitespace<sup>p113</sup>](#) found in MathML elements whose content models do not allow straight text by pretending for the purposes of MathML content models, layout, and rendering that that text is actually wrapped in an [mtext<sup>p395</sup>](#) element in the [MathML namespace<sup>p101</sup>](#). (Such text is not, however, conforming.)

User agents must act as if any MathML element whose contents does not match the element's content model was replaced, for the purposes of MathML layout and rendering, by an [merror<sup>p395</sup>](#) element in the [MathML namespace<sup>p101</sup>](#) containing some appropriate error message.

Support:	
Chrome	24+
IE	None
Firefox	2+
iOS Safari	5.0-5.1+
UC Browser for Android	9.9+(limited)
Safari	5.1+
Opera (limited)	9.5-9.6+
IE Mobile	None
Firefox for Android	33+

Source: [caniuse.com](#)

To enable authors to use MathML tools that only accept MathML in its XML form, interactive HTML user agents are encouraged to provide a way to export any MathML fragment as an XML namespace-well-formed XML fragment.

The semantics of MathML elements are defined by the MathML specification and [other applicable specifications<sup>p56</sup>](#). [MATHML]<sup>p151</sup>

### Example

Here is an example of the use of MathML in an HTML document:

```
<!DOCTYPE html>
<html>
 <head>
 <title>The quadratic formula</title>
 </head>
 <body>
 <h1>The quadratic formula</h1>
 <p>
 <math>
 <mi>x</mi>
 <mo>=</mo>
 <mfrac>
 <mrow>
 <mo form="prefix">-</mo> <mi>b</mi>
 <mo>±</mo>
 <msqrt>
 <msup> <mi>b</mi> <mn>2</mn> </msup>
 <mo>-</mo>
 <mn>4</mn> <mo></mo> <mi>a</mi> <mo></mo> <mi>c</mi>
 </msqrt>
 </mrow>
 <mrow>
 <mn>2</mn> <mo></mo> <mi>a</mi>
 </mrow>
 </mfrac>
 </math>
 </p>
 </body>
</html>
```

## 4.8.19 SVG

The **svg** element from the [SVG namespace<sup>p101</sup>](#) falls into the [embedded content<sup>p116</sup>](#), [phrasing content<sup>p116</sup>](#), and [flow content<sup>p115</sup>](#) categories for purposes of the content models in this specification.

To enable authors to use SVG tools that only accept SVG in its XML form, interactive HTML user agents are encouraged to provide a way to export any SVG fragment as an XML namespace-well-formed XML fragment.

When the SVG `foreignObject` element contains elements from the [HTML namespace<sup>p101</sup>](#), such elements must all be [flow content<sup>p115</sup>](#).

The content model for `title` elements in the [SVG namespace<sup>p101</sup>](#) inside [HTML documents<sup>p51</sup>](#) is [phrasing content<sup>p116</sup>](#). (This further constrains the requirements given in the SVG specification.)

The semantics of SVG elements are defined by the SVG specification and [other applicable specifications<sup>p56</sup>](#). [SVG]<sup>p153</sup>

Spec bugs:	<a href="#">13648</a> , <a href="#">13649</a>

Source: [caniuse.com](#)

### Note

```
doc = iframe . getSVGDocumentp397()
doc = embed . getSVGDocumentp397()
doc = object . getSVGDocumentp397()
```

Returns the [Document<sup>p102</sup>](#) object, in the case of [iframe<sup>p299</sup>](#), [embed<sup>p307</sup>](#), or [object<sup>p310</sup>](#) elements being used to embed SVG images.

The [getSVGDocument\(\)<sup>p397</sup>](#) method must run the following steps:

1. If the element has no [nested browsing context<sup>b763</sup>](#), then return null and abort these steps.
2. If the [active document<sup>b762</sup>](#) of the [nested browsing context<sup>b763</sup>](#) does not have the [same<sup>b778</sup> effective script origin<sup>b776</sup>](#) as the element's [node document](#), then return null and abort these steps.
3. If the [nested browsing context<sup>b763</sup>](#)'s [active document<sup>b762</sup>](#) was created by the [page load processing model for XML files<sup>p797</sup>](#) section because the sniffed type of the resource in the [navigate<sup>p791</sup>](#) algorithm was [image/svg+xml<sup>p1146</sup>](#), then return that [Document<sup>p102</sup>](#) object and abort these steps.
4. Otherwise, return null.

#### 4.8.20 Dimension attributes

**Author requirements:** The **width** and **height** attributes on [img<sup>p272</sup>](#), [iframe<sup>p299</sup>](#), [embed<sup>p307</sup>](#), [object<sup>p310</sup>](#), [video<sup>p317</sup>](#), and, when their [type<sup>p454</sup>](#) attribute is in the [Image Button<sup>p479</sup>](#) state, [input<sup>p452</sup>](#) elements may be specified to give the dimensions of the visual content of the element (the width and height respectively, relative to the nominal direction of the output medium), in CSS pixels. The attributes, if specified, must have values that are [valid non-negative integers<sup>p61</sup>](#).

The specified dimensions given may differ from the dimensions specified in the resource itself, since the resource may have a resolution that differs from the CSS pixel resolution. (On screens, CSS pixels have a resolution of 96ppi, but in general the CSS pixel resolution depends on the reading distance.) If both attributes are specified, then one of the following statements must be true:

- *specified width - 0.5 ≤ specified height \* target ratio ≤ specified width + 0.5*
- *specified height - 0.5 ≤ specified width / target ratio ≤ specified height + 0.5*
- *specified height = specified width = 0*

The **target ratio** is the ratio of the intrinsic width to the intrinsic height in the resource. The **specified width** and **specified height** are the values of the [width<sup>p397</sup>](#) and [height<sup>p397</sup>](#) attributes respectively.

The two attributes must be omitted if the resource in question does not have both an intrinsic width and an intrinsic height.

If the two attributes are both zero, it indicates that the element is not intended for the user (e.g. it might be a part of a service to count page views).

**Note** *The dimension attributes are not intended to be used to stretch the image.*

**User agent requirements:** User agents are expected to use these attributes [as hints for the rendering<sup>p1082</sup>](#).

The **width** and **height** IDL attributes on the [iframe<sup>p299</sup>](#), [embed<sup>p307</sup>](#), [object<sup>p310</sup>](#), and [video<sup>p317</sup>](#) elements must [reflect<sup>p88</sup>](#) the respective content attributes of the same name.

**Note** *For [iframe<sup>p299</sup>](#), [embed<sup>p307</sup>](#), and [object<sup>p310</sup>](#) the IDL attributes are [DOMString<sup>p49</sup>](#); for [video<sup>p317</sup>](#) the IDL attributes are [unsigned long<sup>p50</sup>](#).*

**Note** *The corresponding IDL attributes for [img<sup>p286</sup>](#) and [input<sup>p458</sup>](#) elements are defined in those respective elements' sections, as they are slightly more specific to those elements' other behaviours.*

4.9.1 The `table` element**Categories**<sup>p113</sup>:

[Flow content](#)<sup>p115</sup>.  
[Palpable content](#)<sup>p117</sup>.

**Contexts in which this element can be used**<sup>p113</sup>:

Where [flow content](#)<sup>p115</sup> is expected.

**Content model**<sup>p113</sup>:

In this order: optionally a [caption](#)<sup>p405</sup> element, followed by zero or more [colgroup](#)<sup>p406</sup> elements, followed optionally by a [thead](#)<sup>p409</sup> element, followed optionally by a [tfoot](#)<sup>p410</sup> element, followed by either zero or more [tbody](#)<sup>p408</sup> elements or one or more [tr](#)<sup>p411</sup> elements, followed optionally by a [tfoot](#)<sup>p410</sup> element (but there can only be one [tfoot](#)<sup>p410</sup> element child in total), optionally intermixed with one or more [script-supporting elements](#)<sup>p117</sup>.

**Tag omission in text/html**<sup>p113</sup>:

Neither tag is omissible.

**Content attributes**<sup>p113</sup>:

[Global attributes](#)<sup>p120</sup>

[sortable](#)<sup>p422</sup> — Enables a sorting interface for the table

**DOM interface**<sup>p113</sup>:

```
IDL
interface HTMLTableElement : HTMLElement {
 attribute HTMLTableCaptionElement? caption;
 HTMLElement createCaption();
 void deleteCaption();
 attribute HTMLTableSectionElement? tHead;
 HTMLElement createTHead();
 void deleteTHead();
 attribute HTMLTableSectionElement? tFoot;
 HTMLElement createTFoot();
 void deleteTFoot();
 readonly attribute HTMLCollection tBodies;
 HTMLElement createTBody();
 readonly attribute HTMLCollection rows;
 HTMLElement insertRow(optional long index = -1);
 void deleteRow(long index);
 attribute boolean sortable;
 void stopSorting();

 // also has obsolete members
};
```

The [table](#)<sup>p398</sup> element [represents](#)<sup>p111</sup> data with more than one dimension, in the form of a [table](#)<sup>p417</sup>.

The [table](#)<sup>p398</sup> element takes part in the [table model](#)<sup>p417</sup>. Tables have rows, columns, and cells given by their descendants. The rows and columns form a grid; a table's cells must completely cover that grid without overlap.

**Note** *Precise rules for determining whether this conformance requirement is met are described in the description of the [table model](#)<sup>p417</sup>.*

Authors are encouraged to provide information describing how to interpret complex tables. Guidance on how to [provide such information](#)<sup>p402</sup> is given below.

Tables must not be used as layout aids. Historically, some Web authors have misused tables in HTML as a way to control their page layout. This usage is non-conforming, because tools attempting to extract tabular data from such documents would obtain very confusing results. In particular, users of accessibility tools like screen readers are likely to find it very difficult to navigate pages with tables used for layout.

**Note** There are a variety of alternatives to using HTML tables for layout, primarily using CSS positioning and the CSS table model. [CSS]<sup>p1149</sup>

Tables can be complicated to understand and navigate. To help users with this, user agents should clearly delineate cells in a table from each other, unless the user agent has classified the table as a (non-conforming) layout table.

**Note** Authors and implementors are encouraged to consider using some of the [table design techniques](#)<sup>p405</sup> described below to make tables easier to navigate for users.

User agents, especially those that do table analysis on arbitrary content, are encouraged to find heuristics to determine which tables actually contain data and which are merely being used for layout. This specification does not define a precise heuristic, but the following are suggested as possible indicators:

Feature	Indication
The use of the <code>role</code> <sup>p54</sup> attribute with the value <code>presentation</code>	Probably a layout table
The use of the non-conforming <code>border</code> <sup>p1101</sup> attribute with the non-conforming value 0	Probably a layout table
The use of the non-conforming <code>cellspacing</code> <sup>p1101</sup> and <code>cellpadding</code> <sup>p1101</sup> attributes with the value 0	Probably a layout table
The use of <code>caption</code> <sup>p405</sup> , <code>thead</code> <sup>p409</sup> , or <code>th</code> <sup>p414</sup> elements	Probably a non-layout table
The use of the <code>headers</code> <sup>p416</sup> and <code>scope</code> <sup>p414</sup> attributes	Probably a non-layout table
The use of the non-conforming <code>border</code> <sup>p1101</sup> attribute with a value other than 0	Probably a non-layout table
Explicit visible borders set using CSS	Probably a non-layout table
The use of the <code>summary</code> <sup>p1098</sup> attribute	Not a good indicator (both layout and non-layout tables have historically been given this attribute)

**Note** It is quite possible that the above suggestions are wrong. Implementors are urged to provide feedback elaborating on their experiences with trying to create a layout table detection heuristic.

If a `table`<sup>p398</sup> element has a (non-conforming) `summary`<sup>p1098</sup> attribute, and the user agent has not classified the table as a layout table, the user agent may report the contents of that attribute to the user.

The `sortable`<sup>p422</sup> attribute is used in the [table sorting model](#)<sup>p422</sup>.

**Note**

`table . caption`<sup>p400</sup> [= value]

Returns the table's `caption`<sup>p405</sup> element.

Can be set, to replace the `caption`<sup>p405</sup> element.

`caption = table . createCaption`<sup>p400</sup>()

Ensures the table has a `caption`<sup>p405</sup> element, and returns it.

`table . deleteCaption`<sup>p400</sup>()

Ensures the table does not have a `caption`<sup>p405</sup> element.

`table . tHead`<sup>p400</sup> [= value]

Returns the table's `thead`<sup>p409</sup> element.

Can be set, to replace the `thead`<sup>p409</sup> element. If the new value is not a `thead`<sup>p409</sup> element, throws a `HierarchyRequestError`<sup>p50</sup> exception.

`thead = table . createTHead`<sup>p400</sup>()

Ensures the table has a `thead`<sup>p409</sup> element, and returns it.

`table . deleteTHead`<sup>p400</sup>()

Ensures the table does not have a `thead`<sup>p409</sup> element.

**table.tFoot<sup>p401</sup> [= value]**

Returns the table's [tfoot<sup>p410</sup>](#) element.

Can be set, to replace the [tfoot<sup>p410</sup>](#) element. If the new value is not a [tfoot<sup>p410</sup>](#) element, throws a [HierarchyRequestError<sup>p50</sup>](#) exception.

**tfoot = table.createTFoot<sup>p401</sup>()**

Ensures the table has a [tfoot<sup>p410</sup>](#) element, and returns it.

**table.deleteTFoot<sup>p401</sup>()**

Ensures the table does not have a [tfoot<sup>p410</sup>](#) element.

**table.tBodies<sup>p401</sup>**

Returns an [HTMLCollection<sup>p51</sup>](#) of the [tbody<sup>p408</sup>](#) elements of the table.

**tbody = table.createTBody<sup>p401</sup>()**

Creates a [tbody<sup>p408</sup>](#) element, inserts it into the table, and returns it.

**table.rows<sup>p401</sup>**

Returns an [HTMLCollection<sup>p51</sup>](#) of the [tr<sup>p411</sup>](#) elements of the table.

**tr = table.insertRow<sup>p401</sup>([ index ])**

Creates a [tr<sup>p411</sup>](#) element, along with a [tbody<sup>p408</sup>](#) if required, inserts them into the table at the position given by the argument, and returns the [tr<sup>p411</sup>](#).

The position is relative to the rows in the table. The index -1, which is the default if the argument is omitted, is equivalent to inserting at the end of the table.

If the given position is less than -1 or greater than the number of rows, throws an [IndexSizeError<sup>p50</sup>](#) exception.

**table.deleteRow<sup>p401</sup>(index)**

Removes the [tr<sup>p411</sup>](#) element with the given position in the table.

The position is relative to the rows in the table. The index -1 is equivalent to deleting the last row of the table.

If the given position is less than -1 or greater than the index of the last row, or if there are no rows, throws an [IndexSizeError<sup>p50</sup>](#) exception.

The [caption](#) IDL attribute must return, on getting, the first [caption<sup>p405</sup>](#) element child of the [table<sup>p398</sup>](#) element, if any, or null otherwise. On setting, the first [caption<sup>p405</sup>](#) element child of the [table<sup>p398</sup>](#) element, if any, must be removed, and the new value, if not null, must be inserted as the first node of the [table<sup>p398</sup>](#) element.

The [createCaption\(\)](#) method must return the first [caption<sup>p405</sup>](#) element child of the [table<sup>p398</sup>](#) element, if any; otherwise a new [caption<sup>p405</sup>](#) element must be created, inserted as the first node of the [table<sup>p398</sup>](#) element, and then returned.

The [deleteCaption\(\)](#) method must remove the first [caption<sup>p405</sup>](#) element child of the [table<sup>p398</sup>](#) element, if any.

The [tHead](#) IDL attribute must return, on getting, the first [thead<sup>p409</sup>](#) element child of the [table<sup>p398</sup>](#) element, if any, or null otherwise. On setting, if the new value is null or a [thead<sup>p409</sup>](#) element, the first [thead<sup>p409</sup>](#) element child of the [table<sup>p398</sup>](#) element, if any, must be removed, and the new value, if not null, must be inserted immediately before the first element in the [table<sup>p398</sup>](#) element that is neither a [caption<sup>p405</sup>](#) element nor a [colgroup<sup>p406</sup>](#) element, if any, or at the end of the table if there are no such elements. If the new value is neither null nor a [thead<sup>p409</sup>](#) element, then a [HierarchyRequestError<sup>p50</sup>](#) DOM exception must be thrown instead.

The [createTHead\(\)](#) method must return the first [thead<sup>p409</sup>](#) element child of the [table<sup>p398</sup>](#) element, if any; otherwise a new [thead<sup>p409</sup>](#) element must be created and inserted immediately before the first element in the [table<sup>p398</sup>](#) element that is neither a [caption<sup>p405</sup>](#) element nor a [colgroup<sup>p406</sup>](#) element, if any, or at the end of the table if there are no such elements, and then that new element must be returned.

The [deleteTHead\(\)](#) method must remove the first [thead<sup>p409</sup>](#) element child of the [table<sup>p398</sup>](#) element, if any.

The `tFoot` IDL attribute must return, on getting, the first `tfoot`<sup>p410</sup> element child of the `table`<sup>p398</sup> element, if any, or null otherwise. On setting, if the new value is null or a `tfoot`<sup>p410</sup> element, the first `tfoot`<sup>p410</sup> element child of the `table`<sup>p398</sup> element, if any, must be removed, and the new value, if not null, must be inserted immediately before the first element in the `table`<sup>p398</sup> element that is neither a `caption`<sup>p405</sup> element, a `colgroup`<sup>p406</sup> element, nor a `thead`<sup>p409</sup> element, if any, or at the end of the table if there are no such elements. If the new value is neither null nor a `tfoot`<sup>p410</sup> element, then a `HierarchyRequestError`<sup>p50</sup> DOM exception must be thrown instead.

The `createTFoot()` method must return the first `tfoot`<sup>p410</sup> element child of the `table`<sup>p398</sup> element, if any; otherwise a new `tfoot`<sup>p410</sup> element must be created and inserted immediately before the first element in the `table`<sup>p398</sup> element that is neither a `caption`<sup>p405</sup> element, a `colgroup`<sup>p406</sup> element, nor a `thead`<sup>p409</sup> element, if any, or at the end of the table if there are no such elements, and then that new element must be returned.

The `deleteTFoot()` method must remove the first `tfoot`<sup>p410</sup> element child of the `table`<sup>p398</sup> element, if any.

The `tBodies` attribute must return an `HTMLCollection`<sup>p51</sup> rooted at the `table`<sup>b398</sup> node, whose filter matches only `tbody`<sup>p408</sup> elements that are children of the `table`<sup>b398</sup> element.

The `createTBody()` method must create a new `tbody`<sup>p408</sup> element, insert it immediately after the last `tbody`<sup>p408</sup> element child in the `table`<sup>p398</sup> element, if any, or at the end of the `table`<sup>p398</sup> element if the `table`<sup>p398</sup> element has no `tbody`<sup>p408</sup> element children, and then must return the new `tbody`<sup>p408</sup> element.

The `rows` attribute must return an `HTMLCollection`<sup>p51</sup> rooted at the `table`<sup>p398</sup> node, whose filter matches only `tr`<sup>p411</sup> elements that are either children of the `table`<sup>b398</sup> element, or children of `thead`<sup>p409</sup>, `tbody`<sup>p408</sup>, or `tfoot`<sup>p410</sup> elements that are themselves children of the `table`<sup>b398</sup> element. The elements in the collection must be ordered such that those elements whose parent is a `thead`<sup>p409</sup> are included first, in `tree order`<sup>p42</sup>, followed by those elements whose parent is either a `table`<sup>p398</sup> or `tbody`<sup>p408</sup> element, again in `tree order`<sup>p42</sup>, followed finally by those elements whose parent is a `tfoot`<sup>p410</sup> element, still in `tree order`<sup>p42</sup>.

The behaviour of the `insertRow(index)` method depends on the state of the table. When it is called, the method must act as required by the first item in the following list of conditions that describes the state of the table and the `index` argument:

↪ If `index` is less than `-1` or greater than the number of elements in `rows`<sup>p401</sup> collection:

The method must throw an `IndexSizeError`<sup>p50</sup> exception.

↪ If the `rows`<sup>p401</sup> collection has zero elements in it, and the `table`<sup>p398</sup> has no `tbody`<sup>p408</sup> elements in it:

The method must create a `tbody`<sup>p408</sup> element, then create a `tr`<sup>p411</sup> element, then append the `tr`<sup>p411</sup> element to the `tbody`<sup>p408</sup> element, then append the `tbody`<sup>p408</sup> element to the `table`<sup>p398</sup> element, and finally return the `tr`<sup>p411</sup> element.

↪ If the `rows`<sup>p401</sup> collection has zero elements in it:

The method must create a `tr`<sup>p411</sup> element, append it to the last `tbody`<sup>p408</sup> element in the table, and return the `tr`<sup>p411</sup> element.

↪ If `index` is `-1` or equal to the number of items in `rows`<sup>p401</sup> collection:

The method must create a `tr`<sup>p411</sup> element, and append it to the parent of the last `tr`<sup>p411</sup> element in the `rows`<sup>p401</sup> collection. Then, the newly created `tr`<sup>p411</sup> element must be returned.

↪ Otherwise:

The method must create a `tr`<sup>p411</sup> element, insert it immediately before the `index`th `tr`<sup>p411</sup> element in the `rows`<sup>p401</sup> collection, in the same parent, and finally must return the newly created `tr`<sup>p411</sup> element.

When the `deleteRow(index)` method is called, the user agent must run the following steps:

1. If `index` is equal to `-1`, then `index` must be set to the number of items in the `rows`<sup>p401</sup> collection, minus one.
2. Now, if `index` is less than zero, or greater than or equal to the number of elements in the `rows`<sup>p401</sup> collection, the method must instead throw an `IndexSizeError`<sup>p50</sup> exception, and these steps must be aborted.
3. Otherwise, the method must remove the `index`th element in the `rows`<sup>p401</sup> collection from its parent.

The `stopSorting()`<sup>p435</sup> method is used in the `table sorting model`<sup>p422</sup>.

The IDL attribute `sortable` must `reflect`<sup>p88</sup> the `sortable`<sup>p422</sup> content attribute.

**Example**

Here is an example of a table being used to mark up a Sudoku puzzle. Observe the lack of headers, which are not necessary in such a table.

```

<section>
 <style scoped>
 table { border-collapse: collapse; border: solid thick; }
 colgroup, tbody { border: solid medium; }
 td { border: solid thin; height: 1.4em; width: 1.4em; text-align: center; padding: 0; }
 </style>
 <h1>Today's Sudoku</h1>
 <table>
 <colgroup><col><col><col>
 <colgroup><col><col><col>
 <colgroup><col><col><col>
 <tbody>
 <tr> <td> 1 <td> 2 <td> 3 <td> 4 <td> 5 <td> 6 <td> 7 <td> 8 <td> 9
 <tr> <td> 2 <td> 3 <td> 4 <td> 5 <td> 6 <td> 7 <td> 8 <td> 9
 <tr> <td> 3 <td> 4 <td> 5 <td> 6 <td> 7 <td> 8 <td> 9 <td> 1
 <tr> <td> 4 <td> 5 <td> 6 <td> 7 <td> 8 <td> 9 <td> 1 <td> 2
 <tr> <td> 5 <td> 6 <td> 7 <td> 8 <td> 9 <td> 1 <td> 2 <td> 3
 <tr> <td> 6 <td> 7 <td> 8 <td> 9 <td> 1 <td> 2 <td> 3 <td> 4
 <tr> <td> 7 <td> 8 <td> 9 <td> 1 <td> 2 <td> 3 <td> 4 <td> 5
 <tr> <td> 8 <td> 9 <td> 1 <td> 2 <td> 3 <td> 4 <td> 5 <td> 6
 <tr> <td> 9 <td> 1 <td> 2 <td> 3 <td> 4 <td> 5 <td> 6 <td> 7
 </tbody>
 </table>
</section>

```

#### 4.9.1.1 Techniques for describing tables

For tables that consist of more than just a grid of cells with headers in the first row and headers in the first column, and for any table in general where the reader might have difficulty understanding the content, authors should include explanatory information introducing the table. This information is useful for all users, but is especially useful for users who cannot see the table, e.g. users of screen readers.

Such explanatory information should introduce the purpose of the table, outline its basic cell structure, highlight any trends or patterns, and generally teach the user how to use the table.

For instance, the following table:

Characteristics with positive and negative sides		
Negative	Characteristic	Positive
Sad	Mood	Happy
Failing	Grade	Passing

...might benefit from a description explaining the way the table is laid out, something like "Characteristics are given in the second column, with the negative side in the left column and the positive side in the right column".

There are a variety of ways to include this information, such as:

##### In prose, surrounding the table

###### Example

```

<p>In the following table, characteristics are given in the second column, with the negative side in the left column and the positive side in the right column.</p>
<table>
 <caption>Characteristics with positive and negative sides</caption>
 <thead>
 <tr>
 <th id="n"> Negative
 <th> Characteristic
 <th> Positive
 </tr>
 </thead>
 <tbody>
 <tr>
 <td> Sad </td>
 <td> Mood </td>
 <td> Happy </td>
 </tr>
 <tr>
 <td> Failing </td>
 <td> Grade </td>
 <td> Passing </td>
 </tr>
 </tbody>
</table>

```

```

<tbody>
 <tr>
 <td headers="n r1"> Sad
 <th id="r1"> Mood
 <td> Happy
 <tr>
 <td headers="n r2"> Failing
 <th id="r2"> Grade
 <td> Passing
 </table>

```

#### In the table's caption<sup>p405</sup>

##### Example

```

<table>
 <caption>
 Characteristics with positive and negative sides.
 <p>Characteristics are given in the second column, with the
 negative side in the left column and the positive side in the right
 column.</p>
 </caption>
 <thead>
 <tr>
 <th id="n"> Negative
 <th> Characteristic
 <th> Positive
 </thead>
 <tbody>
 <tr>
 <td headers="n r1"> Sad
 <th id="r1"> Mood
 <td> Happy
 <tr>
 <td headers="n r2"> Failing
 <th id="r2"> Grade
 <td> Passing
 </tbody>
 </table>

```

#### In the table's caption<sup>p405</sup>, in a details<sup>p567</sup> element

##### Example

```

<table>
 <caption>
 Characteristics with positive and negative sides.
 <details>
 <summary>Help</summary>
 <p>Characteristics are given in the second column, with the
 negative side in the left column and the positive side in the right
 column.</p>
 </details>
 </caption>
 <thead>
 <tr>
 <th id="n"> Negative
 <th> Characteristic
 <th> Positive
 </thead>
 <tbody>
 <tr>
 <td headers="n r1"> Sad
 <th id="r1"> Mood
 <td> Happy
 <tr>
 <td headers="n r2"> Failing
 <th id="r2"> Grade

```

```
<td> Passing
</table>
```

#### Next to the table, in the same figure<sup>p202</sup>

##### Example

```
<figure>
 <figcaption>Characteristics with positive and negative sides</figcaption>
 <p>Characteristics are given in the second column, with the
 negative side in the left column and the positive side in the right
 column.</p>
 <table>
 <thead>
 <tr>
 <th id="n"> Negative
 <th> Characteristic
 <th> Positive
 <tbody>
 <tr>
 <td headers="n r1"> Sad
 <th id="r1"> Mood
 <td> Happy
 <tr>
 <td headers="n r2"> Failing
 <th id="r2"> Grade
 <td> Passing
 </table>
</figure>
```

#### Next to the table, in a figure<sup>p202</sup>'s figcaption<sup>p205</sup>

##### Example

```
<figure>
 <figcaption>
 Characteristics with positive and negative sides
 <p>Characteristics are given in the second column, with the
 negative side in the left column and the positive side in the right
 column.</p>
 </figcaption>
 <table>
 <thead>
 <tr>
 <th id="n"> Negative
 <th> Characteristic
 <th> Positive
 <tbody>
 <tr>
 <td headers="n r1"> Sad
 <th id="r1"> Mood
 <td> Happy
 <tr>
 <td headers="n r2"> Failing
 <th id="r2"> Grade
 <td> Passing
 </table>
</figure>
```

Authors may also use other techniques, or combinations of the above techniques, as appropriate.

The best option, of course, rather than writing a description explaining the way the table is laid out, is to adjust the table such that no explanation is needed.

##### Example

In the case of the table used in the examples above, a simple rearrangement of the table so that the headers are on the top and left sides removes the need for an explanation as well as removing the need for the use of [headers<sup>p416</sup>](#) attributes:

```
<table>
 <caption>Characteristics with positive and negative sides</caption>
 <thead>
 <tr>
 <th> Characteristic
 <th> Negative
 <th> Positive
 </tr>
 <tbody>
 <tr>
 <th> Mood
 <td> Sad
 <td> Happy
 </tr>
 <tr>
 <th> Grade
 <td> Failing
 <td> Passing
 </tr>
 </tbody>
</table>
```

#### 4.9.1.2 Techniques for table design

Good table design is key to making tables more readable and usable.

In visual media, providing column and row borders and alternating row backgrounds can be very effective to make complicated tables more readable.

For tables with large volumes of numeric content, using monospaced fonts can help users see patterns, especially in situations where a user agent does not render the borders. (Unfortunately, for historical reasons, not rendering borders on tables is a common default.)

In speech media, table cells can be distinguished by reporting the corresponding headers before reading the cell's contents, and by allowing users to navigate the table in a grid fashion, rather than serialising the entire contents of the table in source order.

Authors are encouraged to use CSS to achieve these effects.

User agents are encouraged to render tables using these techniques whenever the page does not use CSS and the table is not classified as a layout table.

#### 4.9.2 The [caption](#) element

**Categories<sup>p113</sup>:**

None.

**Contexts in which this element can be used<sup>p113</sup>:**

As the first element child of a [table<sup>p398</sup>](#) element.

**Content model<sup>p113</sup>:**

[Flow content<sup>p115</sup>](#), but with no descendant [table<sup>p398</sup>](#) elements.

**Tag omission in text/html<sup>p113</sup>:**

A [caption<sup>p405</sup>](#) element's [end tag<sup>p944</sup>](#) can be omitted if the [caption<sup>p405</sup>](#) element is not immediately followed by a [space character<sup>p58</sup>](#) or a [comment<sup>p952</sup>](#).

**Content attributes<sup>p113</sup>:**

[Global attributes<sup>p120</sup>](#)

**DOM interface<sup>p113</sup>:**

IDL

```
interface HTMLTableCaptionElement : HTMLElement {
 // also has obsolete members
};
```

The [caption<sup>p405</sup>](#) element [represents<sup>p111</sup>](#) the title of the [table<sup>p398</sup>](#) that is its parent, if it has a parent and that is a [table<sup>p398</sup>](#) element.

The [caption<sup>p405</sup>](#) element takes part in the [table model<sup>p417</sup>](#).

When a [table<sup>p398</sup>](#) element is the only content in a [figure<sup>p202</sup>](#) element other than the [figcaption<sup>p205</sup>](#), the [caption<sup>p405</sup>](#) element should be omitted in favor of the [figcaption<sup>p205</sup>](#).

A caption can introduce context for a table, making it significantly easier to understand.

**Example**

Consider, for instance, the following table:

1	2	3	4	5	6
1	2	3	4	5	6
2	3	4	5	6	7
3	4	5	6	7	8
4	5	6	7	8	9
5	6	7	8	9	10
6	7	8	9	10	11
6	7	8	9	10	11

In the abstract, this table is not clear. However, with a caption giving the table's number (for reference in the main prose) and explaining its use, it makes more sense:

```
<caption>
<p>Table 1.
<p>This table shows the total score obtained from rolling two
six-sided dice. The first row represents the value of the first die,
the first column the value of the second die. The total is given in
the cell that corresponds to the values of the two dice.
</caption>
```

This provides the user with more context:

*Table 1.*

*This table shows the total score obtained from rolling two six-sided dice. The first row represents the value of the first die, the first column the value of the second die. The total is given in the cell that corresponds to the values of the two dice.*

1	2	3	4	5	6
1	2	3	4	5	6
2	3	4	5	6	7
3	4	5	6	7	8
4	5	6	7	8	9
5	6	7	8	9	10
6	7	8	9	10	11
6	7	8	9	10	11

#### 4.9.3 The **colgroup** element

**Categories<sup>p113</sup>:**

None.

#### Contexts in which this element can be used<sup>p113</sup>:

As a child of a `table`<sup>p398</sup> element, after any `caption`<sup>p405</sup> elements and before any `thead`<sup>p409</sup>, `tbody`<sup>p408</sup>, `tfoot`<sup>p410</sup>, and `tr`<sup>p411</sup> elements.

#### Content model<sup>p113</sup>:

If the `span`<sup>p407</sup> attribute is present: [Nothing](#)<sup>p114</sup>.

If the `span`<sup>p407</sup> attribute is absent: Zero or more `col`<sup>p407</sup> and `template`<sup>p604</sup> elements.

#### Tag omission in text/html<sup>p113</sup>:

A `colgroup`<sup>p406</sup> element's `start tag`<sup>p944</sup> can be omitted if the first thing inside the `colgroup`<sup>p406</sup> element is a `col`<sup>p407</sup> element, and if the element is not immediately preceded by another `colgroup`<sup>p406</sup> element whose `end tag`<sup>p944</sup> has been omitted. (It can't be omitted if the element is empty.)

A `colgroup`<sup>p406</sup> element's `end tag`<sup>p944</sup> can be omitted if the `colgroup`<sup>p406</sup> element is not immediately followed by a [space character](#)<sup>p58</sup> or a [comment](#)<sup>p952</sup>.

#### Content attributes<sup>p113</sup>:

[Global attributes](#)<sup>p120</sup>

`span`<sup>p407</sup> — Number of columns spanned by the element

#### DOM interface<sup>p113</sup>:

```
IDL interface HTMLTableColElement : HTMLElement {
 attribute unsigned long span;
 // also has obsolete members
};
```

The `colgroup`<sup>p406</sup> element [represents](#)<sup>p111</sup> a [group](#)<sup>p417</sup> of one or more `columns`<sup>p417</sup> in the `table`<sup>p398</sup> that is its parent, if it has a parent and that is a `table`<sup>p398</sup> element.

If the `colgroup`<sup>p406</sup> element contains no `col`<sup>p407</sup> elements, then the element may have a `span` content attribute specified, whose value must be a [valid non-negative integer](#)<sup>p61</sup> greater than zero.

The `colgroup`<sup>p406</sup> element and its `span`<sup>p407</sup> attribute take part in the [table model](#)<sup>p417</sup>.

The `span` IDL attribute must [reflect](#)<sup>p88</sup> the content attribute of the same name. The value must be [limited to only non-negative numbers greater than zero](#)<sup>p89</sup>.

## 4.9.4 The `col` element

#### Categories<sup>p113</sup>:

None.

#### Contexts in which this element can be used<sup>p113</sup>:

As a child of a `colgroup`<sup>p406</sup> element that doesn't have a `span`<sup>p408</sup> attribute.

#### Content model<sup>p113</sup>:

[Nothing](#)<sup>p114</sup>.

#### Tag omission in text/html<sup>p113</sup>:

No `end tag`<sup>p944</sup>.

#### Content attributes<sup>p113</sup>:

[Global attributes](#)<sup>p120</sup>

`span`<sup>p408</sup> — Number of columns spanned by the element

#### DOM interface<sup>p113</sup>:

`HTMLTableColElement`<sup>p407</sup>, same as for `colgroup`<sup>p406</sup> elements. This interface defines one member, `span`<sup>p408</sup>.

If a `col`<sup>p407</sup> element has a parent and that is a `colgroup`<sup>p406</sup> element that itself has a parent that is a `table`<sup>p398</sup> element, then the `col`<sup>p407</sup> element represents<sup>p111</sup> one or more `columns`<sup>p417</sup> in the `column group`<sup>p417</sup> represented by that `colgroup`<sup>p406</sup>.

The element may have a `span` content attribute specified, whose value must be a [valid non-negative integer](#)<sup>p61</sup> greater than zero.

The `col`<sup>p407</sup> element and its `span`<sup>p408</sup> attribute take part in the [table model](#)<sup>p417</sup>.

The `span` IDL attribute must [reflect](#)<sup>p88</sup> the content attribute of the same name. The value must be [limited to only non-negative numbers greater than zero](#)<sup>p89</sup>.

#### 4.9.5 The `tbody` element

##### Categories<sup>p113</sup>:

None.

##### Contexts in which this element can be used<sup>p113</sup>:

As a child of a `table`<sup>p398</sup> element, after any `caption`<sup>p405</sup>, `colgroup`<sup>p406</sup>, and `thead`<sup>p409</sup> elements, but only if there are no `tr`<sup>p411</sup> elements that are children of the `table`<sup>p398</sup> element.

##### Content model<sup>p113</sup>:

Zero or more `tr`<sup>p411</sup> and [script-supporting](#)<sup>p117</sup> elements

##### Tag omission in text/html<sup>p113</sup>:

A `tbody`<sup>p408</sup> element's [start tag](#)<sup>p944</sup> can be omitted if the first thing inside the `tbody`<sup>p408</sup> element is a `tr`<sup>p411</sup> element, and if the element is not immediately preceded by a `tbody`<sup>p408</sup>, `thead`<sup>p409</sup>, or `tfoot`<sup>p410</sup> element whose [end tag](#)<sup>p944</sup> has been omitted. (It can't be omitted if the element is empty.)

A `tbody`<sup>p408</sup> element's [end tag](#)<sup>p944</sup> can be omitted if the `tbody`<sup>p408</sup> element is immediately followed by a `tbody`<sup>p408</sup> or `tfoot`<sup>p410</sup> element, or if there is no more content in the parent element.

##### Content attributes<sup>p113</sup>:

[Global attributes](#)<sup>p120</sup>

##### DOM interface<sup>p113</sup>:

```
IDL interface HTMLTableSectionElement : HTMLElement {
 readonly attribute HTMLCollection rows;
 HTMLElement insertRow(optional long index = -1);
 void deleteRow(long index);

 // also has obsolete members
};
```

The `HTMLTableSectionElement`<sup>p408</sup> interface is also used for `thead`<sup>p409</sup> and `tfoot`<sup>p410</sup> elements.

The `tbody`<sup>p408</sup> element represents<sup>p111</sup> a `block`<sup>p417</sup> of `rows`<sup>p417</sup> that consist of a body of data for the parent `table`<sup>p398</sup> element, if the `tbody`<sup>p408</sup> element has a parent and it is a `table`<sup>p398</sup>.

The `tbody`<sup>p408</sup> element takes part in the [table model](#)<sup>p417</sup>.

Note

`tbody . rowsp409`

Returns an [HTMLCollection<sup>p51</sup>](#) of the [tr<sup>p411</sup>](#) elements of the table section.

`tr = tbody . insertRowp409([ index ])`

Creates a [tr<sup>p411</sup>](#) element, inserts it into the table section at the position given by the argument, and returns the [tr<sup>p411</sup>](#).

The position is relative to the rows in the table section. The index  $-1$ , which is the default if the argument is omitted, is equivalent to inserting at the end of the table section.

If the given position is less than  $-1$  or greater than the number of rows, throws an [IndexSizeError<sup>p50</sup>](#) exception.

`tbody . deleteRowp409(index)`

Removes the [tr<sup>p411</sup>](#) element with the given position in the table section.

The position is relative to the rows in the table section. The index  $-1$  is equivalent to deleting the last row of the table section.

If the given position is less than  $-1$  or greater than the index of the last row, or if there are no rows, throws an [IndexSizeError<sup>p50</sup>](#) exception.

The `rows` attribute must return an [HTMLCollection<sup>p51</sup>](#) rooted at the element, whose filter matches only [tr<sup>p411</sup>](#) elements that are children of the element.

The `insertRow(index)` method must, when invoked on an element *table section*, act as follows:

If `index` is less than  $-1$  or greater than the number of elements in the [rows<sup>p409</sup>](#) collection, the method must throw an [IndexSizeError<sup>p50</sup>](#) exception.

If `index` is  $-1$  or equal to the number of items in the [rows<sup>p409</sup>](#) collection, the method must create a [tr<sup>p411</sup>](#) element, append it to the element *table section*, and return the newly created [tr<sup>p411</sup>](#) element.

Otherwise, the method must create a [tr<sup>p411</sup>](#) element, insert it as a child of the *table section* element, immediately before the `index`th [tr<sup>p411</sup>](#) element in the [rows<sup>p409</sup>](#) collection, and finally must return the newly created [tr<sup>p411</sup>](#) element.

The `deleteRow(index)` method must remove the `index`th element in the [rows<sup>p409</sup>](#) collection from its parent. If `index` is less than zero or greater than or equal to the number of elements in the [rows<sup>p409</sup>](#) collection, the method must instead throw an [IndexSizeError<sup>p50</sup>](#) exception.

## 4.9.6 The `thead` element

Spec bugs: [27541](#)

**Categories<sup>p113</sup>:**

None.

**Contexts in which this element can be used<sup>p113</sup>:**

As a child of a [table<sup>p398</sup>](#) element, after any [caption<sup>p405</sup>](#), and [colgroup<sup>p406</sup>](#) elements and before any [tbody<sup>p408</sup>](#), [tfoot<sup>p410</sup>](#), and [tr<sup>p411</sup>](#) elements, but only if there are no other [thead<sup>p409</sup>](#) elements that are children of the [table<sup>p398</sup>](#) element.

**Content model<sup>p113</sup>:**

Zero or more [tr<sup>p411</sup>](#) and [script-supporting<sup>p117</sup>](#) elements

**Tag omission in text/html<sup>p113</sup>:**

A [thead<sup>p409</sup>](#) element's [end tag<sup>p944</sup>](#) can be omitted if the [thead<sup>p409</sup>](#) element is immediately followed by a [tbody<sup>p408</sup>](#) or [tfoot<sup>p410</sup>](#) element.

**Content attributes<sup>p113</sup>:**

[Global attributes<sup>p120</sup>](#)

**DOM interface<sup>p113</sup>:**

[HTMLTableSectionElement<sup>p408</sup>](#), as defined for [tbody<sup>p408</sup>](#) elements.

The `thead`<sup>p409</sup> element represents<sup>p111</sup> the `block`<sup>p417</sup> of `rows`<sup>p417</sup> that consist of the column labels (headers) for the parent `table`<sup>p398</sup> element, if the `thead`<sup>p409</sup> element has a parent and it is a `table`<sup>p398</sup>.

The `thead`<sup>p409</sup> element takes part in the `table model`<sup>p417</sup>.

### Example

This example shows a `thead`<sup>p409</sup> element being used. Notice the use of both `th`<sup>p414</sup> and `td`<sup>p412</sup> elements in the `thead`<sup>p409</sup> element: the first row is the headers, and the second row is an explanation of how to fill in the table.

```

```

## 4.9.7 The `tfoot` element

### Categories<sup>p113</sup>:

None.

### Contexts in which this element can be used<sup>p113</sup>:

As a child of a `table`<sup>p398</sup> element, after any `caption`<sup>p405</sup>, `colgroup`<sup>p406</sup>, and `thead`<sup>p409</sup> elements and before any `tbody`<sup>p408</sup> and `tr`<sup>p411</sup> elements, but only if there are no other `tfoot`<sup>p410</sup> elements that are children of the `table`<sup>p398</sup> element.

As a child of a `table`<sup>p398</sup> element, after any `caption`<sup>p405</sup>, `colgroup`<sup>p406</sup>, `thead`<sup>p409</sup>, `tbody`<sup>p408</sup>, and `tr`<sup>p411</sup> elements, but only if there are no other `tfoot`<sup>p410</sup> elements that are children of the `table`<sup>p398</sup> element.

### Content model<sup>p113</sup>:

Zero or more `tr`<sup>p411</sup> and `script-supporting`<sup>p117</sup> elements

### Tag omission in text/html<sup>p113</sup>:

A `tfoot`<sup>p410</sup> element's `end tag`<sup>p944</sup> can be omitted if the `tfoot`<sup>p410</sup> element is immediately followed by a `tbody`<sup>p408</sup> element, or if there is no more content in the parent element.

### Content attributes<sup>p113</sup>:

`Global attributes`<sup>p120</sup>

#### DOM interface<sup>p113</sup>:

[HTMLTableSectionElement](#), as defined for [tbody](#) elements.

The [tfoot](#) element [represents](#) the [block](#) of [rows](#) that consist of the column summaries (footers) for the parent [table](#) element, if the [tfoot](#) element has a parent and it is a [table](#).

The [tfoot](#) element takes part in the [table model](#).

#### 4.9.8 The [tr](#) element

##### Categories<sup>p113</sup>:

None.

##### Contexts in which this element can be used<sup>p113</sup>:

- As a child of a [thead](#) element.
- As a child of a [tbody](#) element.
- As a child of a [tfoot](#) element.
- As a child of a [table](#) element, after any [caption](#), [colgroup](#), and [thead](#) elements, but only if there are no [tbody](#) elements that are children of the [table](#) element.

##### Content model<sup>p113</sup>:

Zero or more [td](#), [th](#), and [script-supporting](#) elements

##### Tag omission in text/html<sup>p113</sup>:

A [tr](#) element's [end tag](#) can be omitted if the [tr](#) element is immediately followed by another [tr](#) element, or if there is no more content in the parent element.

##### Content attributes<sup>p113</sup>:

[Global attributes](#)

##### DOM interface<sup>p113</sup>:

```
IDL
interface HTMLTableRowElement : HTMLElement {
 readonly attribute long rowIndex;
 readonly attribute long sectionRowIndex;
 readonly attribute HTMLCollection cells;
 HTMLElement insertCell(optional long index = -1);
 void deleteCell(long index);

 // also has obsolete members
};
```

The [tr](#) element [represents](#) a [row](#) of [cells](#) in a [table](#).

The [tr](#) element takes part in the [table model](#).

##### Note

**`tr.rowIndex`**

Returns the position of the row in the table's [rows](#) list.

Returns -1 if the element isn't in a table.

**`tr.sectionRowIndex`**

Returns the position of the row in the table section's [rows](#) list.

Returns `-1` if the element isn't in a table section.

`tr.cellsp412`

Returns an [HTMLCollection<sup>p51</sup>](#) of the `tdp412` and `thp414` elements of the row.

`cell = tr.insertCellp412([ index ])`

Creates a `tdp412` element, inserts it into the table row at the position given by the argument, and returns the `tdp412`.

The position is relative to the cells in the row. The index `-1`, which is the default if the argument is omitted, is equivalent to inserting at the end of the row.

If the given position is less than `-1` or greater than the number of cells, throws an [IndexSizeError<sup>p50</sup>](#) exception.

`tr.deleteCellp412(index)`

Removes the `tdp412` or `thp414` element with the given position in the row.

The position is relative to the cells in the row. The index `-1` is equivalent to deleting the last cell of the row.

If the given position is less than `-1` or greater than the index of the last cell, or if there are no cells, throws an [IndexSizeError<sup>p50</sup>](#) exception.

The `RowIndex` attribute must, if the element has a parent `tablep398` element, or a parent `tbodyp408`, `theadp409`, or `tfootp410` element and a grandparent `tablep398` element, return the index of the `trp411` element in that `tablep398` element's `rowsp401` collection. If there is no such `tablep398` element, then the attribute must return `-1`.

The `sectionRowIndex` attribute must, if the element has a parent `tablep398`, `tbodyp408`, `theadp409`, or `tfootp410` element, return the index of the `trp411` element in the parent element's `rows` collection (for tables, that's the [HTMLTableElement.rows<sup>p401</sup>](#) collection; for table sections, that's the [HTMLTableRowElement.rows<sup>p409</sup>](#) collection). If there is no such parent element, then the attribute must return `-1`.

The `cells` attribute must return an [HTMLCollection<sup>p51</sup>](#) rooted at the `trp411` element, whose filter matches only `tdp412` and `thp414` elements that are children of the `trp411` element.

The `insertCell(index)` method must act as follows:

If `index` is less than `-1` or greater than the number of elements in the `cellsp412` collection, the method must throw an [IndexSizeError<sup>p50</sup>](#) exception.

If `index` is equal to `-1` or equal to the number of items in `cellsp412` collection, the method must create a `tdp412` element, append it to the `trp411` element, and return the newly created `tdp412` element.

Otherwise, the method must create a `tdp412` element, insert it as a child of the `trp411` element, immediately before the `indexth` `tdp412` or `thp414` element in the `cellsp412` collection, and finally must return the newly created `tdp412` element.

The `deleteCell(index)` method must remove the `indexth` element in the `cellsp412` collection from its parent. If `index` is less than zero or greater than or equal to the number of elements in the `cellsp412` collection, the method must instead throw an [IndexSizeError<sup>p50</sup>](#) exception.

## 4.9.9 The `td` element

**Categories<sup>p113</sup>:**

[Sectioning root<sup>p176</sup>](#).

**Contexts in which this element can be used<sup>p113</sup>:**

As a child of a `trp411` element.

**Content model<sup>p113</sup>:**

[Flow content<sup>p115</sup>](#).

### Tag omission in text/html<sup>p113</sup>:

A `td`<sup>p412</sup> element's end tag<sup>p944</sup> can be omitted if the `td`<sup>p412</sup> element is immediately followed by a `td`<sup>p412</sup> or `th`<sup>p414</sup> element, or if there is no more content in the parent element.

### Content attributes<sup>p113</sup>:

#### Global attributes<sup>p120</sup>

`colspan`<sup>p416</sup> — Number of columns that the cell is to span

`rowspan`<sup>p416</sup> — Number of rows that the cell is to span

`headers`<sup>p416</sup> — The header cells for this cell

### DOM interface<sup>p113</sup>:

IDL

```
interface HTMLTableDataCellElement : HTMLTableCellElement {
 // also has obsolete members
};
```

The `td`<sup>p412</sup> element represents<sup>p111</sup> a data cell<sup>p417</sup> in a table.

The `td`<sup>p412</sup> element and its `colspan`<sup>p416</sup>, `rowspan`<sup>p416</sup>, and `headers`<sup>p416</sup> attributes take part in the table model<sup>p417</sup>.

User agents, especially in non-visual environments or where displaying the table as a 2D grid is impractical, may give the user context for the cell when rendering the contents of a cell; for instance, giving its position in the table model<sup>p417</sup>, or listing the cell's header cells (as determined by the algorithm for assigning header cells<sup>p421</sup>). When a cell's header cells are being listed, user agents may use the value of `abbr`<sup>p415</sup> attributes on those header cells, if any, instead of the contents of the header cells themselves.

### Example

In this example, we see a snippet of a Web application consisting of a grid of editable cells (essentially a simple spreadsheet). One of the cells has been configured to show the sum of the cells above it. Three have been marked as headings, which use `th`<sup>p414</sup> elements instead of `td`<sup>p412</sup> elements. A script would attach event handlers to these elements to maintain the total.

```
<table>
 <tr>
 <th><input value="Name">
 <th><input value="Paid ($)">
 <tr>
 <td><input value="Jeff">
 <td><input value="14">
 <tr>
 <td><input value="Britta">
 <td><input value="9">
 <tr>
 <td><input value="Abed">
 <td><input value="25">
 <tr>
 <td><input value="Shirley">
 <td><input value="2">
 <tr>
 <td><input value="Annie">
 <td><input value="5">
 <tr>
 <td><input value="Troy">
 <td><input value="5">
 <tr>
 <td><input value="Pierce">
 <td><input value="1000">
 <tr>
 <th><input value="Total">
```

```
<td><output value="1060">
</table>
```

#### 4.9.10 The `th` element

##### Categories<sup>p113</sup>:

If the `th`<sup>p414</sup> element is a [sorting interface `th` element](#)<sup>p423</sup>: [Interactive content](#)<sup>p116</sup>.

Otherwise: None.

##### Contexts in which this element can be used<sup>p113</sup>:

As a child of a `tr`<sup>p411</sup> element.

##### Content model<sup>p113</sup>:

[Flow content](#)<sup>p115</sup>, but with no [header](#)<sup>b171</sup>, [footer](#)<sup>p173</sup>, [sectioning content](#)<sup>p116</sup>, or [heading content](#)<sup>b116</sup> descendants, and if the `th`<sup>p414</sup> element is a [sorting interface `th` element](#)<sup>p423</sup>, no [interactive content](#)<sup>p116</sup> descendants.

##### Tag omission in text/html<sup>p113</sup>:

A `th`<sup>p414</sup> element's [end tag](#)<sup>p944</sup> can be omitted if the `th`<sup>p414</sup> element is immediately followed by a `td`<sup>p412</sup> or `th`<sup>p414</sup> element, or if there is no more content in the parent element.

##### Content attributes<sup>b113</sup>:

###### [Global attributes](#)<sup>p120</sup>

[colspan](#)<sup>p416</sup> — Number of columns that the cell is to span

[rowspan](#)<sup>p416</sup> — Number of rows that the cell is to span

[headers](#)<sup>p416</sup> — The header cells for this cell

[scope](#)<sup>p414</sup> — Specifies which cells the header cell applies to

[abbr](#)<sup>p415</sup> — Alternative label to use for the header cell when referencing the cell in other contexts

[sorted](#)<sup>p423</sup> — [Column sort direction](#)<sup>p423</sup> and [ordinality](#)<sup>p423</sup>

##### DOM interface<sup>p113</sup>:

IDL	<pre>interface HTMLTableHeaderCellElement : HTMLElement {   attribute DOMString scope;   attribute DOMString abbr;   attribute DOMString sorted;   void sort(); };</pre>
-----	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------

The `th`<sup>p414</sup> element [represents](#)<sup>p111</sup> a header [cell](#)<sup>p417</sup> in a table.

The `th`<sup>p414</sup> element may have a [scope](#) content attribute specified. The [scope](#)<sup>p414</sup> attribute is an [enumerated attribute](#)<sup>p60</sup> with five states, four of which have explicit keywords:

##### The `row` keyword, which maps to the `row` state

The `row` state means the header cell applies to some of the subsequent cells in the same row(s).

##### The `col` keyword, which maps to the `column` state

The `column` state means the header cell applies to some of the subsequent cells in the same column(s).

##### The `rowgroup` keyword, which maps to the `row group` state

The `row group` state means the header cell applies to all the remaining cells in the row group. A `th`<sup>p414</sup> element's [scope](#)<sup>p414</sup> attribute must not be in the [row group](#)<sup>p414</sup> state if the element is not anchored in a [row group](#)<sup>p417</sup>.

##### The `colgroup` keyword, which maps to the `column group` state

The `column group` state means the header cell applies to all the remaining cells in the column group. A `th`<sup>p414</sup> element's [scope](#)<sup>p414</sup> attribute must not be in the [column group](#)<sup>p414</sup> state if the element is not anchored in a [column group](#)<sup>p417</sup>.

##### The `auto` state

The `auto` state makes the header cell apply to a set of cells selected based on context.

The `scope`<sup>p414</sup> attribute's `missing value default`<sup>p60</sup> is the `auto` state.

The `th`<sup>p414</sup> element may have an `abbr` content attribute specified. Its value must be an alternative label for the header cell, to be used when referencing the cell in other contexts (e.g. when describing the header cells that apply to a data cell). It is typically an abbreviated form of the full header cell, but can also be an expansion, or merely a different phrasing.

The `sorted`<sup>p423</sup> attribute is used in the [table sorting model](#)<sup>p422</sup>.

The `th`<sup>p414</sup> element and its `colspan`<sup>p416</sup>, `rowspan`<sup>p416</sup>, `headers`<sup>p416</sup>, and `scope`<sup>p414</sup> attributes take part in the [table model](#)<sup>p417</sup>.

The `sort()`<sup>p435</sup> method is used in the [table sorting model](#)<sup>p422</sup>.

The `scope` IDL attribute must [reflect](#)<sup>p88</sup> the content attribute of the same name, [limited to only known values](#)<sup>p89</sup>.

The `abbr` and `sorted` IDL attributes must [reflect](#)<sup>p88</sup> the content attributes of the same name.

### Example

The following example shows how the `scope`<sup>p414</sup> attribute's `rowgroup`<sup>p414</sup> value affects which data cells a header cell applies to.

Here is a markup fragment showing a table:

```
<table>
 <thead>
 <tr> <th> ID <th> Measurement <th> Average <th> Maximum
 <tbody>
 <tr> <td> <th scope=rowgroup> Cats <td> <td>
 <tr> <td> 93 <th scope=row> Legs <td> 3.5 <td> 4
 <tr> <td> 10 <th scope=row> Tails <td> 1 <td> 1
 <tbody>
 <tr> <td> <th scope=rowgroup> English speakers <td> <td>
 <tr> <td> 32 <th scope=row> Legs <td> 2.67 <td> 4
 <tr> <td> 35 <th scope=row> Tails <td> 0.33 <td> 1
 </table>
```

This would result in the following table:

ID	Measurement	Average	Maximum
<b>Cats</b>			
93	Legs	3.5	4
10	Tails	1	1
<b>English speakers</b>			
32	Legs	2.67	4
35	Tails	0.33	1

The headers in the first row all apply directly down to the rows in their column.

The headers with the explicit `scope`<sup>p414</sup> attributes apply to all the cells in their row group other than the cells in the first column.

The remaining headers apply just to the cells to the right of them.

ID	Measurement	Average	Maximum
	Cats		
93	Legs	3.5	4
10	Tails	1	1
	English speakers		
32	Legs	2.67	4
35	Tails	0.33	1

#### 4.9.11 Attributes common to `td` and `th` elements

The `td` and `th` elements may have a `colspan` content attribute specified, whose value must be a [valid non-negative integer](#) greater than zero.

The `td` and `th` elements may also have a `rowspan` content attribute specified, whose value must be a [valid non-negative integer](#). For this attribute, the value zero means that the cell is to span all the remaining rows in the row group.

These attributes give the number of columns and rows respectively that the cell is to span. These attributes must not be used to overlap cells, as described in the description of the [table model](#).

The `td` and `th` element may have a `headers` content attribute specified. The `headers` attribute, if specified, must contain a string consisting of an [unordered set of unique space-separated tokens](#) that are [case-sensitive](#), each of which must have the value of an `ID` of a `th` element taking part in the same [table](#) as the `td` or `th` element (as defined by the [table model](#)).

A `th` element with `ID` `id` is said to be *directly targeted* by all `td` and `th` elements in the same [table](#) that have `headers` attributes whose values include as one of their tokens the `ID` `id`. A `th` element `A` is said to be *targeted* by a `th` or `td` element `B` if either `A` is *directly targeted* by `B` or if there exists an element `C` that is itself *targeted* by the element `B` and `A` is *directly targeted* by `C`.

A `th` element must not be *targeted* by itself.

The `colspan`, `rowspan`, and `headers` attributes take part in the [table model](#).

The `td` and `th` elements implement interfaces that inherit from the `HTMLTableCellElement` interface:

```
IDL
interface HTMLTableCellElement : HTMLElement {
 attribute unsigned long colSpan;
 attribute unsigned long rowSpan;
 [PutForwards=value] readonly attribute DOMSettableTokenList headers;
 readonly attribute long cellIndex;

 // also has obsolete members
};
```

Note

### `cell . cellIndexp417`

Returns the position of the cell in the row's `cellsp412` list. This does not necessarily correspond to the *x*-position of the cell in the table, since earlier cells might cover multiple rows or columns.

Returns `-1` if the element isn't in a row.

The `colSpan` IDL attribute must `reflectp88` the `colspanp416` content attribute. Its default value is `1`.

The `rowSpan` IDL attribute must `reflectp88` the `rowspanp416` content attribute. Its default value is `1`.

The `headers` IDL attribute must `reflectp88` the content attribute of the same name.

The `cellIndex` IDL attribute must, if the element has a parent `trp411` element, return the index of the cell's element in the parent element's `cellsp412` collection. If there is no such parent element, then the attribute must return `-1`.

## 4.9.12 Processing model

The various table elements and their content attributes together define the **table model**.

A **table** consists of cells aligned on a two-dimensional grid of **slots** with coordinates  $(x, y)$ . The grid is finite, and is either empty or has one or more slots. If the grid has one or more slots, then the *x* coordinates are always in the range  $0 \leq x < x_{width}$ , and the *y* coordinates are always in the range  $0 \leq y < y_{height}$ . If one or both of  $x_{width}$  and  $y_{height}$  are zero, then the table is empty (has no slots). Tables correspond to `tablep398` elements.

A **cell** is a set of slots anchored at a slot  $(cell_x, cell_y)$ , and with a particular *width* and *height* such that the cell covers all the slots with coordinates  $(x, y)$  where  $cell_x \leq x < cell_x + width$  and  $cell_y \leq y < cell_y + height$ . Cells can either be *data cells* or *header cells*. Data cells correspond to `tdp412` elements, and header cells correspond to `thp414` elements. Cells of both types can have zero or more associated header cells.

It is possible, in certain error cases, for two cells to occupy the same slot.

A **row** is a complete set of slots from  $x=0$  to  $x=x_{width}-1$ , for a particular value of *y*. Rows usually correspond to `trp411` elements, though a **row group**<sup>p417</sup> can have some implied `rowsp417` at the end in some cases involving `cellsp417` spanning multiple rows.

A **column** is a complete set of slots from  $y=0$  to  $y=y_{height}-1$ , for a particular value of *x*. Columns can correspond to `colp407` elements. In the absence of `colp407` elements, columns are implied.

A **row group** is a set of `rowsp417` anchored at a slot  $(0, group_y)$  with a particular *height* such that the row group covers all the slots with coordinates  $(x, y)$  where  $0 \leq x < x_{width}$  and  $group_y \leq y < group_y + height$ . Row groups correspond to `tbodyp408`, `theadp409`, and `tfootp410` elements. Not every row is necessarily in a row group.

A **column group** is a set of `columnsp417` anchored at a slot  $(group_x, 0)$  with a particular *width* such that the column group covers all the slots with coordinates  $(x, y)$  where  $group_x \leq x < group_x + width$  and  $0 \leq y < y_{height}$ . Column groups correspond to `colgroupp406` elements. Not every column is necessarily in a column group.

**Row groups**<sup>p417</sup> cannot overlap each other. Similarly, **column groups**<sup>p417</sup> cannot overlap each other.

A `cellp417` cannot cover slots that are from two or more **row groups**<sup>p417</sup>. It is, however, possible for a cell to be in multiple **column groups**<sup>p417</sup>. All the slots that form part of one cell are part of zero or one **row groups**<sup>p417</sup> and zero or more **column groups**<sup>p417</sup>.

In addition to `cellsp417`, `columnsp417`, `rowsp417`, `row groupsp417`, and `column groupsp417`, `tablesp417` can have a `captionp405` element associated with them. This gives the table a heading, or legend.

A **table model error** is an error with the data represented by `tablep398` elements and their descendants. Documents must not have table model errors.

#### 4.9.12.1 Forming a table

To determine which elements correspond to which slots in a `table`<sup>p417</sup> associated with a `table`<sup>p398</sup> element, to determine the dimensions of the table (`xwidth` and `yheight`), and to determine if there are any `table model errors`<sup>p417</sup>, user agents must use the following algorithm:

1. Let `xwidth` be zero.
2. Let `yheight` be zero.
3. Let `pending tfoot`<sup>p410</sup> elements be a list of `tfoot`<sup>p410</sup> elements, initially empty.
4. Let `the table` be the `table`<sup>p417</sup> represented by the `table`<sup>p398</sup> element. The `xwidth` and `yheight` variables give `the table`'s dimensions. `The table` is initially empty.
5. If the `table`<sup>p398</sup> element has no children elements, then return `the table` (which will be empty), and abort these steps.
6. Associate the first `caption`<sup>p405</sup> element child of the `table`<sup>p398</sup> element with `the table`. If there are no such children, then it has no associated `caption`<sup>p405</sup> element.
7. Let the `current element` be the first element child of the `table`<sup>p398</sup> element.

If a step in this algorithm ever requires the `current element` to be **advanced to the next child of the `table`** when there is no such next child, then the user agent must jump to the step labeled `end`, near the end of this algorithm.

8. While the `current element` is not one of the following elements, `advance`<sup>p418</sup> the `current element` to the next child of the `table`<sup>p398</sup>:
  - `colgroup`<sup>p406</sup>
  - `thead`<sup>p409</sup>
  - `tbody`<sup>p408</sup>
  - `tfoot`<sup>p410</sup>
  - `tr`<sup>p411</sup>
9. If the `current element` is a `colgroup`<sup>p406</sup>, follow these substeps:
  1. **Column groups:** Process the `current element` according to the appropriate case below:
    - ↪ **If the `current element` has any `col`<sup>p407</sup> element children**  
Follow these steps:
      1. Let `xstart` have the value of `xwidth`.
      2. Let the `current column` be the first `col`<sup>p407</sup> element child of the `colgroup`<sup>p406</sup> element.
      3. **Columns:** If the `current column` `col`<sup>p407</sup> element has a `span`<sup>p408</sup> attribute, then parse its value using the [rules for parsing non-negative integers](#)<sup>p61</sup>.  
If the result of parsing the value is not an error or zero, then let `span` be that value.  
Otherwise, if the `col`<sup>p407</sup> element has no `span`<sup>p408</sup> attribute, or if trying to parse the attribute's value resulted in an error or zero, then let `span` be 1.
      4. Increase `xwidth` by `span`.
      5. Let the last `span` `columns`<sup>p417</sup> in `the table` correspond to the `current column` `col`<sup>p407</sup> element.
      6. If `current column` is not the last `col`<sup>p407</sup> element child of the `colgroup`<sup>p406</sup> element, then let the `current column` be the next `col`<sup>p407</sup> element child of the `colgroup`<sup>p406</sup> element, and return to the step labeled `columns`.
      7. Let all the last `columns`<sup>p417</sup> in `the table` from  $x=xstart$  to  $x=xwidth-1$  form a new `column group`<sup>p417</sup>, anchored at the slot  $(xstart, 0)$ , with width  $xwidth-xstart$ , corresponding to the `colgroup`<sup>p406</sup> element.

↪ **If the `current element` has no `col`<sup>p407</sup> element children**

1. If the `colgroup`<sup>p406</sup> element has a `span`<sup>p407</sup> attribute, then parse its value using the [rules for parsing non-negative integers](#)<sup>p61</sup>.  
If the result of parsing the value is not an error or zero, then let `span` be that value.

Otherwise, if the `colgroup`<sup>p406</sup> element has no `span`<sup>p407</sup> attribute, or if trying to parse the attribute's value resulted in an error or zero, then let `span` be 1.

2. Increase  $xwidth$  by `span`.
3. Let the last `span` `columns`<sup>p417</sup> in the `table` form a new `column group`<sup>p417</sup>, anchored at the slot  $(xwidth\text{-}span, 0)$ , with width `span`, corresponding to the `colgroup`<sup>p406</sup> element.
2. Advance<sup>p418</sup> the *current element* to the next child of the `table`<sup>p398</sup>.
3. While the *current element* is not one of the following elements, advance<sup>p418</sup> the *current element* to the next child of the `table`<sup>p398</sup>:
  - `colgroup`<sup>p406</sup>
  - `thead`<sup>p409</sup>
  - `tbody`<sup>p408</sup>
  - `tfoot`<sup>p410</sup>
  - `tr`<sup>p411</sup>
4. If the *current element* is a `colgroup`<sup>p406</sup> element, jump to the step labeled *column groups* above.
10. Let  $y_{current}$  be zero.
11. Let the *list of downward-growing cells* be an empty list.
12. *Rows*: While the *current element* is not one of the following elements, advance<sup>p418</sup> the *current element* to the next child of the `table`<sup>p398</sup>:
  - `thead`<sup>p409</sup>
  - `tbody`<sup>p408</sup>
  - `tfoot`<sup>p410</sup>
  - `tr`<sup>p411</sup>
13. If the *current element* is a `tr`<sup>p411</sup>, then run the *algorithm for processing rows*<sup>p420</sup>, advance<sup>p418</sup> the *current element* to the next child of the `table`<sup>p398</sup>, and return to the step labeled *rows*.
14. Run the *algorithm for ending a row group*<sup>p419</sup>.
15. If the *current element* is a `tfoot`<sup>p410</sup>, then add that element to the list of pending `tfoot`<sup>p410</sup> elements, advance<sup>p418</sup> the *current element* to the next child of the `table`<sup>p398</sup>, and return to the step labeled *rows*.
16. The *current element* is either a `thead`<sup>p409</sup> or a `tbody`<sup>p408</sup>.  
Run the *algorithm for processing row groups*<sup>p419</sup>.
17. Advance<sup>p418</sup> the *current element* to the next child of the `table`<sup>p398</sup>.
18. Return to the step labeled *rows*.
19. *End*: For each `tfoot`<sup>p410</sup> element in the list of pending `tfoot`<sup>p410</sup> elements, in *tree order*<sup>p42</sup>, run the *algorithm for processing row groups*<sup>p419</sup>.
20. If there exists a `row`<sup>p417</sup> or `column`<sup>p417</sup> in the `table` containing only `slots`<sup>p417</sup> that do not have a `cell`<sup>p417</sup> anchored to them, then this is a *table model error*<sup>p417</sup>.
21. Return the `table`.

The **algorithm for processing row groups**, which is invoked by the set of steps above for processing `thead`<sup>p409</sup>, `tbody`<sup>p408</sup>, and `tfoot`<sup>p410</sup> elements, is:

1. Let  $y_{start}$  have the value of  $yheight$ .
2. For each `tr`<sup>p411</sup> element that is a child of the element being processed, in tree order, run the *algorithm for processing rows*<sup>p420</sup>.
3. If  $yheight > y_{start}$ , then let all the last `rows`<sup>p417</sup> in the `table` from  $y=y_{start}$  to  $y=yheight-1$  form a new `row group`<sup>p417</sup>, anchored at the slot with coordinate  $(0, y_{start})$ , with height  $yheight-y_{start}$ , corresponding to the element being processed.
4. Run the *algorithm for ending a row group*<sup>p419</sup>.

The **algorithm for ending a row group**, which is invoked by the set of steps above when starting and ending a block of rows, is:

1. While  $y_{current}$  is less than  $y_{height}$ , follow these steps:

1. Run the [algorithm for growing downward-growing cells](#)<sup>p420</sup>.

2. Increase  $y_{current}$  by 1.

2. Empty the *list of downward-growing cells*.

The **algorithm for processing rows**, which is invoked by the set of steps above for processing  $\text{tr}^{p411}$  elements, is:

1. If  $y_{height}$  is equal to  $y_{current}$ , then increase  $y_{height}$  by 1. ( $y_{current}$  is never greater than  $y_{height}$ .)

2. Let  $x_{current}$  be 0.

3. Run the [algorithm for growing downward-growing cells](#)<sup>p420</sup>.

4. If the  $\text{tr}^{p411}$  element being processed has no  $\text{td}^{p412}$  or  $\text{th}^{p414}$  element children, then increase  $y_{current}$  by 1, abort this set of steps, and return to the algorithm above.

5. Let *current cell* be the first  $\text{td}^{p412}$  or  $\text{th}^{p414}$  element child in the  $\text{tr}^{p411}$  element being processed.

6. *Cells*: While  $x_{current}$  is less than  $x_{width}$  and the slot with coordinate  $(x_{current}, y_{current})$  already has a cell assigned to it, increase  $x_{current}$  by 1.

7. If  $x_{current}$  is equal to  $x_{width}$ , increase  $x_{width}$  by 1. ( $x_{current}$  is never greater than  $x_{width}$ .)

8. If the *current cell* has a  $\text{colspan}^{p416}$  attribute, then [parse that attribute's value](#)<sup>p61</sup>, and let *colspan* be the result.

If parsing that value failed, or returned zero, or if the attribute is absent, then let *colspan* be 1, instead.

9. If the *current cell* has a  $\text{rowspan}^{p416}$  attribute, then [parse that attribute's value](#)<sup>p61</sup>, and let *rowspan* be the result.

If parsing that value failed or if the attribute is absent, then let *rowspan* be 1, instead.

10. If *rowspan* is zero and the  $\text{table}^{p398}$  element's [node document](#) is not set to [quirks mode](#)<sup>p51</sup>, then let *cell grows downward* be true, and set *rowspan* to 1. Otherwise, let *cell grows downward* be false.

11. If  $x_{width} < x_{current} + \text{colspan}$ , then let  $x_{width}$  be  $x_{current} + \text{colspan}$ .

12. If  $y_{height} < y_{current} + \text{rowspan}$ , then let  $y_{height}$  be  $y_{current} + \text{rowspan}$ .

13. Let the slots with coordinates  $(x, y)$  such that  $x_{current} \leq x < x_{current} + \text{colspan}$  and  $y_{current} \leq y < y_{current} + \text{rowspan}$  be covered by a new  $\text{cell}^{p417}$  *c*, anchored at  $(x_{current}, y_{current})$ , which has width *colspan* and height *rowspan*, corresponding to the *current cell* element.

If the *current cell* element is a  $\text{th}^{p414}$  element, let this new cell *c* be a header cell; otherwise, let it be a data cell.

To establish which header cells apply to the *current cell* element, use the [algorithm for assigning header cells](#)<sup>p421</sup> described in the next section.

If any of the slots involved already had a  $\text{cell}^{p417}$  covering them, then this is a [table model error](#)<sup>p417</sup>. Those slots now have two cells overlapping.

14. If *cell grows downward* is true, then add the tuple  $\{c, x_{current}, \text{colspan}\}$  to the *list of downward-growing cells*.

15. Increase  $x_{current}$  by *colspan*.

16. If *current cell* is the last  $\text{td}^{p412}$  or  $\text{th}^{p414}$  element child in the  $\text{tr}^{p411}$  element being processed, then increase  $y_{current}$  by 1, abort this set of steps, and return to the algorithm above.

17. Let *current cell* be the next  $\text{td}^{p412}$  or  $\text{th}^{p414}$  element child in the  $\text{tr}^{p411}$  element being processed.

18. Return to the step labeled *cells*.

When the algorithms above require the user agent to run the **algorithm for growing downward-growing cells**, the user agent must, for each  $\{\text{cell}, \text{cell}_x, \text{width}\}$  tuple in the *list of downward-growing cells*, if any, extend the  $\text{cell}^{p417}$  *cell* so that it also covers the slots with coordinates  $(x, y_{current})$ , where  $\text{cell}_x \leq x < \text{cell}_x + \text{width}$ .

#### 4.9.12.2 Forming relationships between data cells and header cells

Each cell can be assigned zero or more header cells. The algorithm for assigning header cells to a cell *principal cell* is as follows.

1. Let *header list* be an empty list of cells.
2. Let  $(principal_x, principal_y)$  be the coordinate of the slot to which the *principal cell* is anchored.
  - 3⇒ If the *principal cell* has a headers<sup>p416</sup> attribute specified
    1. Take the value of the *principal cell's headers*<sup>p416</sup> attribute and split it on spaces<sup>p80</sup>, letting *id list* be the list of tokens obtained.
    2. For each token in the *id list*, if the first element in the Document<sup>p102</sup> with an ID<sup>p51</sup> equal to the token is a cell in the same table<sup>p417</sup>, and that cell is not the *principal cell*, then add that cell to *header list*.
  - ↪ If *principal cell* does not have a headers<sup>p416</sup> attribute specified
    1. Let *principal width* be the width of the *principal cell*.
    2. Let *principal height* be the height of the *principal cell*.
    3. For each value of *y* from *principal y* to *principal y + principal height - 1*, run the internal algorithm for scanning and assigning header cells<sup>p421</sup>, with the *principal cell*, the *header list*, the initial coordinate  $(principal_x, y)$ , and the increments  $\Delta x = -1$  and  $\Delta y = 0$ .
    4. For each value of *x* from *principal x* to *principal x + principal width - 1*, run the internal algorithm for scanning and assigning header cells<sup>p421</sup>, with the *principal cell*, the *header list*, the initial coordinate  $(x, principal_y)$ , and the increments  $\Delta x = 0$  and  $\Delta y = -1$ .
    5. If the *principal cell* is anchored in a row group<sup>p417</sup>, then add all header cells that are row group headers<sup>p422</sup> and are anchored in the same row group with an *x*-coordinate less than or equal to *principal x + principal width - 1* and a *y*-coordinate less than or equal to *principal y + principal height - 1* to *header list*.
    6. If the *principal cell* is anchored in a column group<sup>p417</sup>, then add all header cells that are column group headers<sup>p422</sup> and are anchored in the same column group with an *x*-coordinate less than or equal to *principal x + principal width - 1* and a *y*-coordinate less than or equal to *principal y + principal height - 1* to *header list*.
  4. Remove all the empty cells<sup>p422</sup> from the *header list*.
  5. Remove any duplicates from the *header list*.
  6. Remove *principal cell* from the *header list* if it is there.
  7. Assign the headers in the *header list* to the *principal cell*.

The internal algorithm for scanning and assigning header cells, given a *principal cell*, a *header list*, an initial coordinate  $(initial_x, initial_y)$ , and  $\Delta x$  and  $\Delta y$  increments, is as follows:

1. Let *x* equal *initial x*.
2. Let *y* equal *initial y*.
3. Let *opaque headers* be an empty list of cells.

#### 4⇒ If *principal cell* is a header cell

Let *in header block* be true, and let *headers from current header block* be a list of cells containing just the *principal cell*.

#### ↪ Otherwise

Let *in header block* be false and let *headers from current header block* be an empty list of cells.

5. Loop: Increment *x* by  $\Delta x$ ; increment *y* by  $\Delta y$ .

**Note** For each invocation of this algorithm, one of  $\Delta x$  and  $\Delta y$  will be  $-1$ , and the other will be  $0$ .

6. If either *x* or *y* is less than  $0$ , then abort this internal algorithm.
7. If there is no cell covering slot  $(x, y)$ , or if there is more than one cell covering slot  $(x, y)$ , return to the substep labeled *loop*.

8. Let *current cell* be the cell covering slot  $(x, y)$ .

9 $\Rightarrow$  If *current cell* is a header cell

1. Set *in header block* to true.
2. Add *current cell* to *headers from current header block*.
3. Let *blocked* be false.

4 $\Rightarrow$  If  $\Delta x$  is 0

If there are any cells in the *opaque headers* list anchored with the same *x*-coordinate as the *current cell*, and with the same width as *current cell*, then let *blocked* be true.

If the *current cell* is not a [column header](#)<sup>p422</sup>, then let *blocked* be true.

4 $\Leftarrow$  If  $\Delta y$  is 0

If there are any cells in the *opaque headers* list anchored with the same *y*-coordinate as the *current cell*, and with the same height as *current cell*, then let *blocked* be true.

If the *current cell* is not a [row header](#)<sup>p422</sup>, then let *blocked* be true.

5. If *blocked* is false, then add the *current cell* to the *headers list*.

4 $\Leftarrow$  If *current cell* is a data cell and *in header block* is true

Set *in header block* to false. Add all the cells in *headers from current header block* to the *opaque headers* list, and empty the *headers from current header block* list.

10. Return to the step labeled *loop*.

A header cell anchored at the slot with coordinate  $(x, y)$  with width *width* and height *height* is said to be a **column header** if any of the following conditions are true:

- The cell's [scope](#)<sup>p414</sup> attribute is in the [column](#)<sup>p414</sup> state, or
- The cell's [scope](#)<sup>p414</sup> attribute is in the [auto](#)<sup>p414</sup> state, and there are no data cells in any of the cells covering slots with *y*-coordinates  $y \dots y+height-1$ .

A header cell anchored at the slot with coordinate  $(x, y)$  with width *width* and height *height* is said to be a **row header** if any of the following conditions are true:

- The cell's [scope](#)<sup>p414</sup> attribute is in the [row](#)<sup>p414</sup> state, or
- The cell's [scope](#)<sup>p414</sup> attribute is in the [auto](#)<sup>p414</sup> state, the cell is not a [column header](#)<sup>p422</sup>, and there are no data cells in any of the cells covering slots with *x*-coordinates  $x \dots x+width-1$ .

A header cell is said to be a **column group header** if its [scope](#)<sup>p414</sup> attribute is in the [column group](#)<sup>p414</sup> state.

A header cell is said to be a **row group header** if its [scope](#)<sup>p414</sup> attribute is in the [row group](#)<sup>p414</sup> state.

A cell is said to be an **empty cell** if it contains no elements and its text content, if any, consists only of [White\\_Space](#)<sup>p58</sup> characters.

#### 4.9.13 Table sorting model

The [sortable](#) attribute on [table](#)<sup>p398</sup> elements is a [boolean attribute](#)<sup>p59</sup>. When present, it indicates that the user agent is to [allow the user to sort](#)<sup>p1077</sup> the [table](#)<sup>p398</sup>.

To make a column sortable in a [table](#)<sup>p398</sup> with a [thead](#)<sup>p409</sup>, the column needs to have [th](#)<sup>p414</sup> element that does not [span multiple columns](#)<sup>p416</sup> in a [thead](#)<sup>p409</sup> above any rows that it is to sort.

To make a column sortable in a [table](#)<sup>p398</sup> without a [thead](#)<sup>p409</sup>, the column needs to have [th](#)<sup>p414</sup> element that does not [span multiple columns](#)<sup>p416</sup> in the first [tr](#)<sup>p411</sup> element of the [table](#)<sup>p398</sup>, where that [tr](#)<sup>p411</sup> element is not in a [tfoot](#)<sup>p410</sup>.

When the user selects a column by which to sort, the user agent sets the `th`<sup>p414</sup> element's `sorted` attribute. This attribute can also be set manually, to indicate that the table should be automatically sorted, even when scripts modify the page on when the page is loaded. Spec bugs: 26650.

The `sorted`<sup>p423</sup> attribute, if specified, must have a value that is a [set of space-separated tokens](#)<sup>p80</sup> consisting of optionally a token whose value is an [ASCII case-insensitive](#)<sup>p58</sup> match for the string "reversed", and optionally a token whose value is a [valid non-negative integer](#)<sup>p81</sup> greater than zero, in either order.

**Note** In other words, ignoring spaces and case, the `sorted`<sup>p423</sup> attribute's value can be empty, "reversed", "1", "reversed 1", or "1 reversed", where "1" is any number equal to or greater than 1.

While one or more `th`<sup>p414</sup> elements in the table have a `sorted`<sup>p423</sup> attribute, the user agent will keep the table's data rows sorted. The value of the attribute controls how the column is used in determining the sort order. The `reversed`<sup>p423</sup> keyword means that the **column sort direction** is reversed, rather than *normal*, which is the default if the keyword is omitted. The number, if present, indicates the **column key ordinality**; if the number is omitted, the column is the primary key, as if the value 1 had been specified.

**Note** Thus, `sorted="1"` indicates the table's primary key, `sorted="2"` its secondary key, and so forth.

A **sorting-capable** `th` element is a `th`<sup>p414</sup> element that matches all the following conditions simultaneously:

- It corresponds to a `cell`<sup>p417</sup> whose *width* is 1. (Specifically, a *header cell*, since this is a `th`<sup>p414</sup> element.)
- There is no `cell`<sup>p417</sup> that corresponds to another **sorting-capable** `th` element<sup>p423</sup> that covers slots in the same `column`<sup>p417</sup> but on a higher (earlier) `row`<sup>p417</sup>.
- If the `cell`<sup>p417</sup>'s `table`<sup>p417</sup> has a `row group`<sup>p417</sup> corresponding to a `thead`<sup>p409</sup> element, the `cell`<sup>p417</sup> is in a `row group`<sup>p417</sup> that corresponds to the *first* `thead`<sup>p409</sup> element of the `cell`<sup>p417</sup>'s `table`<sup>p417</sup>.  
Otherwise: the `cell`<sup>p417</sup> is not in a `row group`<sup>p417</sup> corresponding to a `tfoot`<sup>p410</sup> element, and the `cell`<sup>p417</sup> is in the *first* `row`<sup>p417</sup> of the `table`<sup>p417</sup>.

**Note** In other words, each `column`<sup>p417</sup> can have one **sorting-capable** `th` element<sup>p423</sup>; this will be the highest `th`<sup>p414</sup> in a `thead`<sup>p409</sup> that spans no other columns, or, if there is no `thead`<sup>p409</sup>, the `th`<sup>p414</sup> in the first row (that is not in a `tfoot`<sup>p410</sup>), assuming it spans no columns.

The **sorting-capable** `th` elements of the `table` element `table` are the **sorting-capable** `th` elements<sup>p423</sup> whose `cell`<sup>p417</sup>'s `table`<sup>p417</sup> is `table`.

A `table`<sup>p398</sup> element `table` is a **sorting-capable** `table` element if there are one or more **sorting-capable** `th` elements of the `table` element<sup>p423</sup> `table`.

A `th`<sup>p414</sup> element is a **sorting-enabled** `th` element if it is a **sorting-capable** `th` element<sup>p423</sup> and it has a `sorted`<sup>p423</sup> attribute.

The **sorting-enabled** `th` elements of the `table` element `table` are the **sorting-enabled** `th` elements<sup>p423</sup> whose `cell`<sup>p417</sup>'s `table`<sup>p417</sup> is `table`.

A `table`<sup>p398</sup> element `table` is a **sorting-enabled** `table` element if there are one or more **sorting-capable** `th` elements of the `table` element<sup>p423</sup> `table`, and at least one of them is a **sorting-enabled** `th` element<sup>p423</sup> (i.e. at least one has a `sorted`<sup>p423</sup> attribute).

A `table`<sup>p398</sup> element is a `table` element with a user-agent exposed sorting interface if it is a **sorting-capable** `table` element<sup>p423</sup> and has a `sortable`<sup>p422</sup> attribute specified.

A **sorting interface** `th` element is a **sorting-capable** `th` element<sup>p423</sup> whose `cell`<sup>p417</sup>'s `table`<sup>p417</sup> is a `table` element with a user-agent exposed sorting interface<sup>p423</sup>.

Each `table`<sup>p398</sup> element has a **currently-sorting flag**, which must initially be false.

The `sorted`<sup>p423</sup> attribute must not be specified on `th`<sup>p414</sup> elements that are not **sorting-capable** `th` elements<sup>p423</sup>. The `sortable`<sup>p422</sup> attribute must not be specified on `table`<sup>p398</sup> elements that are not **sorting-capable** `table` elements<sup>p423</sup>.

To determine a `th`<sup>p414</sup> element's `sorted`<sup>p423</sup> attribute's **column sort direction**<sup>p423</sup> and **column key ordinality**<sup>p423</sup>, user agents must use the following algorithm:

1. Let *direction* be *normal*.
2. Let *have explicit direction* be false.
3. Let *ordinality* be 1.
4. Let *have explicit ordinality* be false.
5. Let *tokens* be the result of [splitting the attribute's value on spaces](#)<sup>p80</sup>.
6. For each token *token* in *tokens*, run the appropriate steps from the following list:
  - ↪ If *have explicit direction* is false and *token* is an [ASCII case-insensitive](#)<sup>b58</sup> match for the string "[reversed](#)"<sup>b423</sup>  
Let *direction* be *reversed* and *have explicit direction* be true.
  - ↪ If *have explicit ordinality* is false  
[Parse token as an integer](#)<sup>p60</sup>. If this resulted in an error or the value zero, then ignore the token. Otherwise, set *ordinality* to the parsed value, and set *have explicit ordinality* to true.
  - ↪ Otherwise  
Ignore the token.
7. The [column sort direction](#)<sup>p423</sup> is the value of *direction*, and the [column key ordinality](#)<sup>p423</sup> is the value of *ordinality*.

A [table](#)<sup>p398</sup> must not have two [th](#)<sup>p414</sup> elements whose [sorted](#)<sup>p423</sup> attribute have the same [column key ordinality](#)<sup>p423</sup>.

The **table sorting algorithm**, which is applied to a [table](#)<sup>p398</sup>, is as follows:

1. Let *table* be the [table](#)<sup>p398</sup> element being sorted.
  2. If *table*'s [currently-sorting flag](#)<sup>p423</sup> is true, then abort these steps.
  3. Set *table*'s [currently-sorting flag](#)<sup>p423</sup> to true.
  4. [Fire a simple event](#)<sup>b846</sup> named [sort](#)<sup>p1145</sup> that is cancelable at *table*.
  5. If the event fired in the previous step was canceled, then jump to the step labeled *end* below.
  6. If *table* is not now a [sorting-enabled table element](#)<sup>p423</sup>, then jump to the step labeled *end* below.
- Note** Even if *table* was a [sorting-enabled table element](#)<sup>p423</sup> when the algorithm was invoked, the DOM might have been entirely changed by the event handlers for the [sort](#)<sup>p1145</sup> event, so this has to be verified at this stage, not earlier.
7. Let *key heading cells* be the [sorting-enabled th](#) elements of the [table](#) element<sup>p423</sup> *table*.
  8. Sort *key heading cells* in ascending order of the [column key ordinality](#)<sup>p423</sup> of their [sorted](#)<sup>p423</sup> attributes, with those having the same [column key ordinality](#)<sup>p423</sup> being sorted in [tree order](#)<sup>p42</sup>.
  9. Let *row collection cursor* be a pointer to an element, initially pointing at the first child of *table* that is after *table*'s first [thead](#)<sup>p409</sup>, if any, and that is either a [tbody](#)<sup>p408</sup> or a [tr](#)<sup>p411</sup> element, assuming there is one. If there is no such child, then jump to the step labeled *end* below.
  10. If *table* has no [row group](#)<sup>p417</sup> corresponding to a [thead](#)<sup>p409</sup> element, then set *ignore first group* to true. Otherwise, set it to false.
  11. Run these substeps:
    1. **Row loop:** Let *rows* be an empty list of [tr](#)<sup>p411</sup> elements.
    2. Run these substeps:
      1. Run the appropriate steps from the following list:
        - ↪ If **row collection cursor** points to a [tr](#)<sup>p411</sup> element
          1. **Collect:** Append the element pointed to by *row collection cursor* to *rows*.

2. If there are no `tr`<sup>p411</sup> or `tbody`<sup>p408</sup> children of `table` that are later siblings of the element pointed to by `row collection cursor`, or if the next such child is a `tbody`<sup>p408</sup> element, then jump to the step labeled `group` below.
3. Let `row collection cursor` point to the next `tr`<sup>p411</sup> child of `table` that is a later sibling of the element pointed to by `row collection cursor`.
4. Jump back to the step labeled `collect` above.

↪ If `row collection cursor` points to a `tbody`<sup>p408</sup> element

1. Place all the `tr`<sup>p411</sup> element children of the element pointed to by `row collection cursor` into `rows`, in `tree order`<sup>p42</sup>.
2. If `rows` is empty, jump to the step labeled `increment loop` below.
2. *Group*: Let `groups` be an empty list of groups of `tr`<sup>p411</sup> elements.
3. Let `group` be an empty group of `tr`<sup>p411</sup> elements.
4. Let `group cursor` be a pointer to an element, initially pointing at the first `tr`<sup>p411</sup> element in `rows`.
5. Run these substeps:
  1. *Start group*: Let `pending rows in group` be 1.
  2. Run these substeps:
    1. *Group loop*: Append the `tr`<sup>p411</sup> element pointed to by `group cursor` to `group`.
    2. If there are any `cells`<sup>p417</sup> whose highest `row`<sup>p417</sup>'s element is the one pointed to by `group cursor`, then let `tallest height` be the number of rows covered by the tallest such `cell`<sup>p417</sup>.
    3. If `tallest height` is greater than `pending rows in group` then set `pending rows in group` to `tallest height`.
    4. Decrement `pending rows in group` by one.
    5. Let `group cursor` point to the next `tr`<sup>p411</sup> element in `rows`, if any; otherwise, let it be null.
    6. If `group cursor` is not null and `pending rows in group` is not zero, jump back to the step labeled `group loop`.
  3. Append a new group to `groups` consisting of the `tr`<sup>p411</sup> elements in `group`.
  4. *Empty group*.
  5. If `group cursor` is not null, then jump back to the step labeled `start group`.
6. If `ignore first group` is true, then drop the first group in `groups` and set `ignore first group` to false.
7. Run these steps:
  1. *Drop leading header groups*: If `groups` is now empty, jump to the step labeled `increment loop` below.
  2. If the first group of `groups` consists of `tr`<sup>p411</sup> elements whose element children are all `th`<sup>p414</sup> elements, then drop the first group in `groups` and jump back to the previous step (labeled `drop leading header groups`).
  8. Let `insertion point` be a placeholder in a DOM tree, which can be used to reinsert nodes at a specific point in the DOM. Insert `insertion point` into the parent of the first `tr`<sup>p411</sup> element of the first group in `groups`, immediately before that `tr`<sup>p411</sup> element.
  9. Sort the groups in `groups`, using the following algorithm to decide the relative order of any two groups `a` and `b` (the algorithm either returns that `a` comes before `b`, or that `b` comes before `a`):
    1. Let `key index` be an index into `key heading cells`, initially denoting the first element in the list.

2. Let *direction* be a sort direction, initially *ascending*. Its other possible value is *descending*. When *direction* is *toggled*, that means that if its value is *ascending*, it must be changed to *descending*, and when its value is *descending*, it must be changed to *ascending*.
3. Run these substeps:
  1. *Column loop*: Let *th* be the key index [th<sup>p414</sup>](#) in *key heading cells*.
    2. If *th*'s [sorted<sup>p423</sup>](#) attribute's [column sort direction<sup>p423</sup>](#) is reversed, then toggle *direction*.
    3. Let *tentative order* be the result of [comparing two row groups using the th element<sup>p426</sup>](#) *th*, with *a* and *b* as the rows.
    4. If *tentative order* is not "equal", then jump to the step labeled *return* below.
    5. Increment *key index*.
    6. If *key index* still denotes a [th<sup>p414</sup>](#) element in *key heading cells*, then jump back to the step above labeled *column loop*.
  4. If *a*'s [tr<sup>p411</sup>](#) elements precede *b*'s in [tree order<sup>p422</sup>](#), then let *tentative order* be "a before b". Otherwise, let *tentative order* be "b before a".
  5. *Return*: Return the relative order given by the matching option from the following list:

↪ If *direction* is *ascending* and *tentative order* is "a before b"

Return that *a* comes before *b*.

↪ If *direction* is *ascending* and *tentative order* is "b before a"

Return that *b* comes before *a*.

↪ If *direction* is *descending* and *tentative order* is "a before b"

Return that *b* comes before *a*.

↪ If *direction* is *descending* and *tentative order* is "b before a"

Return that *a* comes before *b*.

When the user agent is required to [compare two row groups using the th element<sup>p417</sup>](#), with *a* and *b* being the two row groups respectively, the user agent must run the following steps:

1. Let *x* be the *x*-coordinate of the slots that [th<sup>p414</sup>](#) covers in its [table<sup>p417</sup>](#).
2. Let *cell<sub>a</sub>* be the element corresponding to the [cell<sup>p417</sup>](#) in the first [row<sup>p417</sup>](#) of group *a* that covers the slot in that [row<sup>p417</sup>](#) whose *x*-coordinate is *x*.

Let *cell<sub>b</sub>* be the element corresponding to the [cell<sup>p417</sup>](#) in the first [row<sup>p417</sup>](#) of group *b* that covers the slot in that [row<sup>p417</sup>](#) whose *x*-coordinate is *x*.

In either case, if there's no [cell<sup>p417</sup>](#) that actually covers the slot, then use the value *null* instead.

3. Let *type<sub>a</sub>* and *value<sub>a</sub>* be the [type and value of the cell<sup>p426</sup>](#) *cell<sub>a</sub>*, as defined below.

Let *type<sub>b</sub>* and *value<sub>b</sub>* be the [type and value of the cell<sup>p426</sup>](#) *cell<sub>b</sub>*, as defined below.

The **type and value of the cell** *cell* are computed as follows.

1. If *cell* is *null*, then the type is "string" and the value is the empty string; abort these steps.
2. If, ignoring [inter-element whitespace<sup>p113</sup>](#) and nodes other than [Element<sup>p51</sup>](#) and [Text<sup>p51</sup>](#) nodes, *cell* has only one child and that child is a [data<sup>p226</sup>](#) element, then the value is the value of that [data<sup>p226</sup>](#) element's [value<sup>p226</sup>](#) attribute, if there is one, or the empty string otherwise; the type is "string".
3. If, ignoring [inter-element whitespace<sup>p113</sup>](#) and nodes other than [Element<sup>p51</sup>](#) and [Text<sup>p51</sup>](#) nodes, *cell* has only one child and that child is a [progress<sup>p518</sup>](#) element, then the value is the value of that [progress<sup>p518</sup>](#) element's [value<sup>p518</sup>](#) attribute, if there is one, or the empty string otherwise; the type is "string".

4. If, ignoring [inter-element whitespace](#)<sup>p113</sup> and nodes other than [Element](#)<sup>p51</sup> and [Text](#)<sup>p51</sup> nodes, *cell* has only one child and that child is a [meter](#)<sup>p519</sup> element, then the value is the value of that [meter](#)<sup>p519</sup> element's [value](#)<sup>p520</sup> attribute, if there is one, or the empty string otherwise; the type is "string".
5. If, ignoring [inter-element whitespace](#)<sup>p113</sup> and nodes other than [Element](#)<sup>p51</sup> and [Text](#)<sup>p51</sup> nodes, *cell* has only one child and that child is a [time](#)<sup>p227</sup> element, then the value is the [machine-readable equivalent of the element's contents](#)<sup>p230</sup>, if any, and the type is the kind of value that is thus obtained (a [month](#)<sup>p67</sup>, a [date](#)<sup>p67</sup>, a [yearless date](#)<sup>p68</sup>, a [time](#)<sup>p69</sup>, a [local date and time](#)<sup>p70</sup>, a [time-zone offset](#)<sup>p71</sup>, a [global date and time](#)<sup>p72</sup>, a [week](#)<sup>p73</sup>, a year, or a [duration](#)<sup>p74</sup>); abort these steps after completing this one.

If there is no machine-readable equivalent, then the type is "string" and the value is the empty string.

If the type is a [month](#)<sup>p67</sup>, a [date](#)<sup>p67</sup>, a [week](#)<sup>p73</sup>, or a year, then change the value to be the instant in time (with no time zone) that describes the earliest moment that the value represents, and change the type to be a [local date and time](#)<sup>p70</sup>.

**Example** For example, if the cell was `<td><time>2011-11-11</time>` then for sorting purposes the value is interpreted as "2011-11-01T00:00:00.000" and the type is treated as a [local date and time](#)<sup>p70</sup> rather than a [month](#)<sup>p67</sup>.

**Example** Similarly, if the cell was `<td><time datetime="2014">MMXIV</time>` then for sorting purposes the value is interpreted as "2014-01-01T00:00:00.000" and the type is treated as a [local date and time](#)<sup>p70</sup> rather than a year.

6. The value is the element's [textContent](#)<sup>p51</sup>. The type is "string".
4. If *typea* and *typeb* are not equal, then: return "a before b" if *typea* is earlier in the following list than *typeb*, otherwise, return "b before a"; then, abort these steps.

1. [time](#)<sup>p69</sup>
2. [yearless date](#)<sup>p68</sup>
3. [local date and time](#)<sup>p70</sup>
4. [global date and time](#)<sup>p72</sup>
5. [time-zone offset](#)<sup>p71</sup>
6. [duration](#)<sup>p74</sup>
7. "string"

5. If *valuea* and *valueb* are equal, then return "equal" and abort these steps.
6. If *typea* and *typeb* are not "string", then: if *valuea* is earlier than *valueb* then return "a before b" and abort these steps, otherwise, return "b before a" and abort these steps.

Values sort in their natural order, with the following additional constraints:

For [time](#)<sup>p69</sup> values, 00:00:00.000 is the earliest value and 23:59:59.999 is the latest value.

For [yearless date](#)<sup>p68</sup> values, 01-01 is the earliest value and 12-31 is the latest value; 02-28 is earlier than 02-29 which is earlier than 03-01.

Values that are [local date and time](#)<sup>p70</sup> compare as if they were in the same time zone.

For [time-zone offset](#)<sup>p71</sup> values, -23:59 is the earliest value and +23:59 is the latest value.

7. Let *componentsa* be the result of [parsing the sort key](#)<sup>p429</sup> *valuea*.

Let *componentsb* be the result of [parsing the sort key](#)<sup>p429</sup> *valueb*.

As described below, *componentsa* and *componentsb* are tuples consisting of a list of *n numbers*, a list of *n number strings*, a list of *n+1 non-numeric strings*, and a list of *2n+1 raw strings*, for any non-negative integer value of *n* (zero or more).

8. Let *order* be the result of a [locale-specific string comparison](#)<sup>p434</sup> of *componentsa*'s first *non-numeric string* and *componentsb*'s first *non-numeric string*, in the context of *th*.

If *order* is not "equal" then return *order* and abort these steps.

9. If *components<sub>a</sub>* and *components<sub>b</sub>* both have exactly one *number*, then run these substeps:
    1. If *components<sub>a</sub>*'s *number* is less than *components<sub>b</sub>*'s *number*, return "a before b".  
If *components<sub>b</sub>*'s *number* is less than *components<sub>a</sub>*'s *number*, return "b before a".
    2. Let *order* be the result of a [locale-specific string comparison<sup>p434</sup>](#) of *components<sub>a</sub>*'s second *non-numeric string* and *components<sub>b</sub>*'s second *non-numeric string*, in the context of *th*.  
If *order* is not "equal" then return *order* and abort these steps.
    3. Let *order* be the result of a [locale-specific string comparison<sup>p434</sup>](#) of *components<sub>a</sub>*'s *number string* and *components<sub>b</sub>*'s *number string*, in the context of *th*.  
If *order* is not "equal" then return *order* and abort these steps.
- Otherwise, run these substeps:
1. If *components<sub>a</sub>* has zero *numbers* but *components<sub>b</sub>* has more than zero *numbers*, return "a before b".  
If *components<sub>b</sub>* has zero *numbers* but *components<sub>a</sub>* has more than zero *numbers*, return "b before a".
  2. If *components<sub>a</sub>* has one *number*, return "a before b".  
If *components<sub>b</sub>* has one *number*, return "b before a".
  3. If *components<sub>a</sub>* and *components<sub>b</sub>* have more than one *number*, run these substeps:
    1. Let *count* be the smaller of the number of *numbers* in *components<sub>a</sub>* and the number of *numbers* in *components<sub>b</sub>*.
    2. For each *number* in *components<sub>a</sub>* and *components<sub>b</sub>* from the first to the *counth*, in order: if *components<sub>a</sub>*'s *number* is less than *components<sub>b</sub>*'s *number*, then return "a before b" and abort these steps; otherwise, if *components<sub>b</sub>*'s *number* is less than *components<sub>a</sub>*'s *number*, return "b before a" and abort these steps.
    3. If *components<sub>a</sub>* has fewer *numbers* than *components<sub>b</sub>*, return "a before b" and abort these steps.  
If *components<sub>b</sub>* has fewer *numbers* than *components<sub>a</sub>*, return "b before a" and abort these steps.
    4. Let *index* be zero.
    5. *String loop*: Let *order* be the result of a [locale-specific string comparison<sup>p434</sup>](#) of *components<sub>a</sub>*'s *indexth number string* and *components<sub>b</sub>*'s *indexth number string*, in the context of *th*.  
If *order* is not "equal" then return *order* and abort these steps.
    6. Increment *index*.
    7. Let *order* be the result of a [locale-specific string comparison<sup>p434</sup>](#) of *components<sub>a</sub>*'s *indexth separator string* and *components<sub>b</sub>*'s *indexth separator string*, in the context of *th*.  
If *order* is not "equal" then return *order* and abort these steps.
    8. If *index* is less than the number of *numbers* in *components<sub>a</sub>* and *components<sub>b</sub>*, jump back to the step labeled *string loop*.
  10. Let *index* be zero.
  11. Run these substeps:

1. *Final loop*: Let *order* be the result of a [raw string comparison<sup>p434</sup>](#) of *components<sub>a</sub>*'s *n*th *raw string* and *components<sub>b</sub>*'s *n*th *raw string*.
  - If *order* is not "equal" then return *order* and abort these steps.
  - Increment *index*.
  - If *index* is less than the number of *raw strings* in *components<sub>a</sub>* and *components<sub>b</sub>*, jump back to the step labeled *final loop*.
12. Return "equal".
10. Let *new order* be a list of [\*tr\*<sup>p411</sup>](#) elements consisting of the [\*tr\*<sup>p411</sup>](#) elements of all the groups in the newly ordered *groups*, with the [\*tr\*<sup>p411</sup>](#) elements being in the same order as the groups to which they belong are in *groups*, and the [\*tr\*<sup>p411</sup>](#) elements within each such group themselves being ordered in [tree order<sup>p42</sup>](#).
11. [Remove<sup>p51</sup>](#) all the [\*tr\*<sup>p411</sup>](#) elements in *new order* from their parents, in [tree order<sup>p42</sup>](#).
12. [Insert<sup>p51</sup>](#) all the [\*tr\*<sup>p411</sup>](#) elements in *new order* into the DOM at the location of *insertion point*, in the order these elements are found in *new order*.
13. Remove *insertion point* from the DOM.
3. *Increment loop*: If there are no [\*tr\*<sup>p411</sup>](#) or [\*tbody\*<sup>p408</sup>](#) children of *table* that are later siblings of the element pointed to by *row collection cursor*, then jump to the step labeled *end* below.
4. Let *row collection cursor* point to the next [\*tr\*<sup>p411</sup>](#) or [\*tbody\*<sup>p408</sup>](#) child of *table* that is a later sibling of the element pointed to by *row collection cursor*.
5. Jump back to the step labeled *row loop* above.
12. *End*: Set *table*'s [currently-sorting flag<sup>p423</sup>](#) to false.

When a user agent is to **parse the sort key value**, it must run the following steps. These return a tuple consisting of a list of *n numbers*, a list of *n number strings*, a list of *n+1 non-numeric strings*, and a list of *2n+1 raw strings*, respectively, for any non-negative integer value of *n* (zero or more).

1. Let *raw strings* be a list of strings initially containing just one entry, an empty string.
2. Let *negatives prejudiced* be false.
 

Let *decimals prejudiced* be false.

Let *exponents prejudiced* be false.
3. Let *buffer* be the empty string.
 

Let *index* be zero.

Let *mode* be "[separator<sup>p430</sup>](#)".

When a subsequent step in this algorithm says to **push the buffer**, the user agent must run the following substeps:

1. Add an entry to *raw strings* that consists of the value of *buffer*.
  2. Add an entry to *raw strings* that is the empty string.
  3. Decrement *index* by one.
  4. Set [\*mode\*<sup>p429</sup>](#) to "[separator<sup>p430</sup>](#)".
4. Let *checkpoint buffer* be the empty string.

Let *checkpoint index* be zero.

When a subsequent step in this algorithm says to **checkpoint**, the user agent must run the following substeps:

1. Set the *checkpoint buffer* to the value of *buffer*.
2. Set the *checkpoint index* to the value of *index*.

When a subsequent step in this algorithm says to **push the checkpoint**, the user agent must run the following substeps:

1. Add an entry to *raw strings* that consists of the value of *checkpoint buffer*.
  2. Add an entry to *raw strings* that is the empty string.
  3. Decrement *index* by one.
  4. Set *mode*<sup>p429</sup> to "separator"<sup>p430</sup>.
5. Run through the following steps repeatedly until the condition in the last step is met.
1. *Top of loop*: If *index* is equal to or greater than the number of characters in *value*, let *c* be EOF. Otherwise, let *c* be the *index*th character in *value*.
  2. Run the appropriate steps from the following list:
    - ↪ If *mode*<sup>p429</sup> is "separator"<sup>p430</sup>  
Run the appropriate substeps from the following list:
      - ↪ If *c* is a **space character**<sup>p58</sup>  
Set *negatives prejudiced* to false.  
  
Set *decimals prejudiced* to false.  
  
Set *exponents prejudiced* to false.  
  
Append *c* to the last entry in *raw strings*.
      - ↪ If *c* is a U+002D HYPHEN-MINUS character (-) and *negatives prejudiced* is false  
Set *buffer* to the value of *c*.  
  
Set *mode*<sup>p429</sup> to "negative"<sup>p430</sup>.
      - ↪ If *c* is a U+002E FULL STOP character (.) and *decimals prejudiced* is false  
Set *buffer* to the value of *c*.  
  
Set *mode*<sup>p429</sup> to "leading-decimal"<sup>p431</sup>.
      - ↪ If *c* is an **ASCII digit**<sup>p58</sup>  
Set *buffer* to the value of *c*.  
  
Set *mode*<sup>p429</sup> to "integral"<sup>p431</sup>.
      - ↪ If *c* is an **uppercase ASCII letter**<sup>p58</sup> or a **lowercase ASCII letter**<sup>p58</sup>  
Set *exponents prejudiced* to true.  
  
Append *c* to the last entry in *raw strings*.
      - ↪ If *c* is EOF  
Do nothing.
      - ↪ Otherwise  
Append *c* to the last entry in *raw strings*.
    - ↪ If *mode*<sup>p429</sup> is "negative"<sup>p430</sup>  
Run the appropriate substeps from the following list:
      - ↪ If *c* is a U+002D HYPHEN-MINUS character (-)  
Set *negatives prejudiced* to true.  
  
Append *buffer* to the last entry in *raw strings*.
      - Append *c* to the last entry in *raw strings*.

Set mode<sup>P429</sup> to "separator"<sup>P430</sup>.

- ↪ If c is a U+002E FULL STOP character (.) and *decimals prejudiced* is false  
Append c to *buffer*.

Set mode<sup>P429</sup> to "leading-decimal"<sup>P431</sup>.

- ↪ If c is an ASCII digit<sup>P58</sup>  
Append c to *buffer*.

Set mode<sup>P429</sup> to "integral"<sup>P431</sup>.

- ↪ Otherwise  
Append *buffer* to the last entry in *raw strings*.

Decrement *index* by one.

Set mode<sup>P429</sup> to "separator"<sup>P430</sup>.

- ↪ If mode<sup>P429</sup> is "integral"

Run the appropriate substeps from the following list:

- ↪ If c is a U+002D HYPHEN-MINUS character (-)  
Set *negatives prejudiced* to true.

Push the buffer<sup>P429</sup>.

- ↪ If c is a U+002E FULL STOP character (.) and *decimals prejudiced* is false  
Checkpoint<sup>P429</sup>.

Append c to *buffer*.

Set mode<sup>P429</sup> to "decimal"<sup>P432</sup>.

- ↪ If c is an ASCII digit<sup>P58</sup>

Append c to the last entry in *raw strings*.

- ↪ If c is a U+0045 LATIN CAPITAL LETTER E character or a U+0065 LATIN SMALL LETTER E character and *exponents prejudiced* is false  
Checkpoint<sup>P429</sup>.

Append c to *buffer*.

Set mode<sup>P429</sup> to "exponent"<sup>P432</sup>.

- ↪ Otherwise

Push the buffer<sup>P429</sup>.

- ↪ If mode<sup>P429</sup> is "leading-decimal"

Run the appropriate substeps from the following list:

- ↪ If c is an ASCII digit<sup>P58</sup>  
Append c to *buffer*.

Set mode<sup>P429</sup> to "decimal"<sup>P432</sup>.

- ↪ Otherwise

Append *buffer* to the last entry in *raw strings*.

Decrement *index* by one.

Set mode<sup>P429</sup> to "separator"<sup>P430</sup>.

↪ If mode<sup>p429</sup> is "decimal"

Run the appropriate substeps from the following list:

↪ If c is a U+002D HYPHEN-MINUS character (-)

Set *negatives prejudiced* to true.

Push the buffer<sup>p429</sup>.

↪ If c is a U+002E FULL STOP character (.) and any of the characters in *value* past the *indexth* character are ASCII digits<sup>p58</sup>

Set *decimals prejudiced* to true.

Push the checkpoint<sup>p430</sup>.

↪ If c is a U+002E FULL STOP character (.) and none of the characters in *value* past the *indexth* character are ASCII digits<sup>p58</sup>

Push the buffer<sup>p429</sup>.

↪ If c is an ASCII digit<sup>p58</sup>

Append c to *buffer*.

↪ If c is a U+0045 LATIN CAPITAL LETTER E character or a U+0065 LATIN SMALL LETTER E character and *exponents prejudiced* is false

Checkpoint<sup>p429</sup>.

Append c to *buffer*.

Set mode<sup>p429</sup> to "exponent<sup>p432</sup>".

↪ Otherwise

Push the buffer<sup>p429</sup>.

↪ If mode<sup>p429</sup> is "exponent"

Run the appropriate substeps from the following list:

↪ If c is a U+002D HYPHEN-MINUS character (-) and *negatives prejudiced* is false

Append c to *buffer*.

Set mode<sup>p429</sup> to "exponent-negative<sup>p432</sup>".

↪ If c is a U+002E FULL STOP character (.)

Set *decimals prejudiced* to true.

Push the checkpoint<sup>p430</sup>.

↪ If c is an ASCII digit<sup>p58</sup>

Append c to *buffer*.

Set mode<sup>p429</sup> to "exponent-number<sup>p433</sup>".

↪ If c is a U+0045 LATIN CAPITAL LETTER E character or a U+0065 LATIN SMALL LETTER E character

Set *exponents prejudiced* to true.

Push the checkpoint<sup>p430</sup>.

↪ Otherwise

Push the checkpoint<sup>p430</sup>.

↪ If mode<sup>p429</sup> is "exponent-negative"

Run the appropriate substeps from the following list:

↪ If c is a U+002D HYPHEN-MINUS character (-)

Set *negatives prejudiced* to true.

[Push the checkpoint<sup>p430</sup>](#).

↪ If  $c$  is a U+002E FULL STOP character (.)

Set *decimals prejudiced* to true.

[Push the checkpoint<sup>p430</sup>](#).

↪ If  $c$  is an ASCII digit<sup>p58</sup>

Append  $c$  to *buffer*.

Set *mode*<sup>p429</sup> to "exponent-negative-number"<sup>p433</sup>.

↪ If  $c$  is a U+0045 LATIN CAPITAL LETTER E character or a U+0065 LATIN SMALL LETTER E character

Set *exponents prejudiced* to true.

[Push the checkpoint<sup>p430</sup>](#).

↪ Otherwise

[Push the checkpoint<sup>p430</sup>](#).

↪ If *mode*<sup>p429</sup> is "exponent-number"

Run the appropriate substeps from the following list:

↪ If  $c$  is a U+002D HYPHEN-MINUS character (-)

Set *negatives prejudiced* to true.

[Push the buffer<sup>p429</sup>](#).

↪ If  $c$  is a U+002E FULL STOP character (.)

Set *decimals prejudiced* to true.

[Push the checkpoint<sup>p430</sup>](#).

↪ If  $c$  is an ASCII digit<sup>p58</sup>

Append  $c$  to *buffer*.

↪ If  $c$  is a U+0045 LATIN CAPITAL LETTER E character or a U+0065 LATIN SMALL LETTER E character

Set *exponents prejudiced* to true.

[Push the checkpoint<sup>p430</sup>](#).

↪ Otherwise

[Push the buffer<sup>p429</sup>](#).

↪ If *mode*<sup>p429</sup> is "exponent-negative-number"

Run the appropriate substeps from the following list:

↪ If  $c$  is a U+002D HYPHEN-MINUS character (-)

Set *negatives prejudiced* to true.

[Push the checkpoint<sup>p430</sup>](#).

↪ If  $c$  is a U+002E FULL STOP character (.)

Set *decimals prejudiced* to true.

[Push the checkpoint<sup>p430</sup>](#).

↪ If  $c$  is an ASCII digit<sup>p58</sup>

Append  $c$  to *buffer*.

↪ If  $c$  is a U+0045 LATIN CAPITAL LETTER E character or a U+0065 LATIN SMALL LETTER E character

Set *exponents prejudiced* to true.

[Push the checkpoint<sup>p430</sup>](#).

↪ **Otherwise**

[Push the buffer<sup>p429</sup>](#).

3. Increment *index* by one.
4. If *index* is greater than the number of characters in *value*, stop repeating these substeps and continue along the overall steps. Otherwise, return to the step labeled *top of loop*.
6. Let *numbers* be an empty list.

Let *number strings* be an empty list.

Let *non-numeric strings* be an empty list.

7. For each even-numbered entry in *raw strings*, in order, starting from the first entry (numbered 0), append an entry to *non-numeric strings* that consists of the result of [trimming and collapsing<sup>p434</sup>](#) the value of the entry.
8. If *raw strings* has more than one entry, then, for each odd-numbered entry in *raw strings*, in order, starting from the second entry (numbered 1), append an entry to *number strings* that consists of the value of the entry, and append an entry to *number strings* that consists of the result of parsing the value of the entry using the [rules for parsing floating-point number values<sup>p62</sup>](#).
9. Return *numbers*, *number strings*, *non-numeric strings*, and *raw strings* respectively.

When the user agent is required by the step above to perform a **locale-specific string comparison** of two strings *a* and *b* in the context of an element *e*, the user agent must apply the Unicode Collation Algorithm, using the Default Unicode Collation Element Table as customised for the [language<sup>p123</sup>](#) of the element *e* in the Common Locale Data Repository, to the strings *a* and *b*, ignoring case. If the result of this algorithm places *a* first, then return "a before b"; if it places *b* first, then return "b before a"; otherwise, if they compare as equal, then return "equal". [\[UCA\]<sup>p1153</sup>](#)  
[\[CLDR\]<sup>p1148</sup>](#)

When the user agent is required by the step above to perform a **raw string comparison** of two strings *a* and *b*, the user agent must apply the Unicode Collation Algorithm, using the Default Unicode Collation Element Table without customizations, to the strings *a* and *b*. If the result of this algorithm places *a* first, then return "a before b"; if it places *b* first, then return "b before a"; otherwise, if they compare as equal, then return "equal". [\[UCA\]<sup>p1153</sup>](#)

Where the steps above refer to **trimming and collapsing** a string *value*, it means running the following algorithm:

1. [Strip leading and trailing whitespace<sup>p59</sup>](#) from *value*.
2. Replace any sequence of one or more [space characters<sup>p58</sup>](#) in *value* with a single U+0020 SPACE character.

When any of the descendants of a [sorting-enabled table element<sup>p423</sup>](#) change in any way (including attributes changing), and when a [table<sup>p398</sup>](#) element becomes a [sorting-enabled table element<sup>p423</sup>](#), the [table<sup>p398</sup>](#) element is said to become a **table with a pending sort**. When a [table<sup>p398</sup>](#) element becomes [a table with a pending sort<sup>p434</sup>](#), the user agent must [queue a microtask<sup>p837</sup>](#) that applies the [table sorting algorithm<sup>p424</sup>](#) to that [table<sup>p398</sup>](#), and then flags the [table<sup>p398</sup>](#) as no longer being [a table with a pending sort<sup>p434</sup>](#).

When the user agent is to **set the sort key** to a [th<sup>p414</sup>](#) element *target*, it must run the following algorithm:

1. Let *table* be the [table<sup>p398</sup>](#) of the [table<sup>p417</sup>](#) of which *target* is a header cell.
2. If [th<sup>p414</sup>](#) is a [sorting-enabled th element<sup>p423</sup>](#) whose [column key ordinality<sup>p423</sup>](#) is 1, then: if its [column sort direction<sup>p423</sup>](#) is *normal*, set that element's [sorted<sup>p423</sup>](#) attribute to the string "reversed", otherwise, set it to the empty string; then, abort these steps.
3. Let *current headers* be the [sorting-enabled th elements of the table element<sup>p423</sup>](#) *table*, excluding *target*.
4. Sort *current headers* by their [sorted<sup>p423</sup>](#) attributes' [column key ordinality<sup>p423</sup>](#), in ascending order, with elements that have the same [column key ordinality<sup>p423</sup>](#) being sorted in [tree order<sup>p42</sup>](#).
5. Let *level* be 2.
6. For each [th<sup>p414</sup>](#) element *th* in *current headers*, in order, run the following substeps:

1. If *th*'s `sorted`<sup>p423</sup> attribute's `column sort direction`<sup>p423</sup> is *normal*, then set *th*'s `sorted`<sup>p423</sup> attribute to a `valid integer`<sup>p60</sup> whose value is *level*. Otherwise, set it to the concatenation of the string "reversed", a U+0020 SPACE character, and a `valid integer`<sup>p60</sup> whose value is *level*.
2. Increment *level* by 1.
7. Set *target*'s `sorted`<sup>p423</sup> attribute to the empty string.

The `activation behaviour`<sup>p725</sup> of a `sorting interface th element`<sup>p423</sup> is to `set the sort key`<sup>p434</sup> to the `th`<sup>p414</sup> element.

**Note** *The table*<sup>p398</sup> will be sorted the next time the user agent performs a microtask checkpoint<sup>p837</sup>.

**Note**

`th.sort`<sup>p435()</sup>

Act as if the user had indicated that this was to be the new primary sort column.

The `table`<sup>p398</sup> won't actually be sorted until the script terminates.

`table.stopSorting`<sup>p435()</sup>

Removes all the `sorted`<sup>p423</sup> attributes that are causing the table to automatically sort its contents, if any.

The `th`<sup>p414</sup> element's `sort()` method, when invoked, must run the following steps:

1. If the `th`<sup>p414</sup> element is not a `sorting-capable th element`<sup>p423</sup>, then abort these steps.
2. `Set the sort key`<sup>p434</sup> to the `th`<sup>p414</sup> element.

**Note** *The table*<sup>p398</sup> will be sorted the next time the user agent performs a microtask checkpoint<sup>p837</sup>.

The `table`<sup>p398</sup> element's `stopSorting()` method, when invoked, must remove the `sorted`<sup>p423</sup> attribute of all the `sorting-enabled th elements of the table element`<sup>p423</sup> on which the method was invoked.

#### 4.9.14 Examples

*This section is non-normative.*

The following shows how might one mark up the bottom part of table 45 of the *Smithsonian physical tables, Volume 71*:

```
<table>
 <caption>Specification values: Steel, Castings,
 Ann. A.S.T.M. A27-16, Class B; * P max. 0.06; S max. 0.05.</caption>
 <thead>
 <tr>
 <th rowspan=2>Grade.</th>
 <th rowspan=2>Yield Point.</th>
 <th colspan=2>Ultimate tensile strength</th>
 <th rowspan=2>Per cent elong. 50.8mm or 2 in.</th>
 <th rowspan=2>Per cent reduct. area.</th>
 </tr>
 <tr>
 <th>kg/mm2</th>
 <th>lb/in2</th>
 </tr>
 </thead>
 <tbody>
 <tr>
 <td>Hard</td>
```

```

<td>0.45 ultimate</td>
<td>56.2</td>
<td>80,000</td>
<td>15</td>
<td>20</td>
</tr>
<tr>
<td>Medium</td>
<td>0.45 ultimate</td>
<td>49.2</td>
<td>70,000</td>
<td>18</td>
<td>25</td>
</tr>
<tr>
<td>Soft</td>
<td>0.45 ultimate</td>
<td>42.2</td>
<td>60,000</td>
<td>22</td>
<td>30</td>
</tr>
</tbody>
</table>

```

This table could look like this:

Specification values: **Steel, Castings, Ann. A.S.T.M. A27-16**, Class B;\* P max. 0.06; S max. 0.05.

Grade.	Yield Point.	Ultimate tensile strength		Per cent elong. 50.8 mm or 2 in.	Per cent reduct. area.
		kg/mm <sup>2</sup>	lb/in <sup>2</sup>		
Hard . . . . .	0.45 ultimate	56.2	80,000	15	20
Medium . . . .	0.45 ultimate	49.2	70,000	18	25
Soft . . . . .	0.45 ultimate	42.2	60,000	22	30

The following shows how one might mark up the gross margin table on page 46 of Apple, Inc's 10-K filing for fiscal year 2008:

```

<table>
<thead>
<tr>
<th></th>
<th>2008</th>
<th>2007</th>
<th>2006</th>
</thead>
<tbody>
<tr>
<th>Net sales</th>
<td>$ 32,479</td>
<td>$ 24,006</td>
<td>$ 19,315</td>
</tr>
<tr>
<th>Cost of sales</th>
<td> 21,334</td>
<td> 15,852</td>
<td> 13,717</td>
</tr>
<tr>
<th>Gross margin</th>
<td>$ 11,145</td>
<td>$ 8,154</td>
</tr>
</tbody>

```

```

<td>$ 5,598
<tfoot>
<tr>
<th>Gross margin percentage
<td>34.3%
<td>34.0%
<td>29.0%
</table>

```

This table could look like this:

	<b>2008</b>	<b>2007</b>	<b>2006</b>
Net sales .....	\$ 32,479	\$ 24,006	\$ 19,315
Cost of sales .....	21,334	15,852	13,717
Gross margin .....	<u>\$ 11,145</u>	<u>\$ 8,154</u>	<u>\$ 5,598</u>
Gross margin percentage .....	34.3%	34.0%	29.0%

The following shows how one might mark up the operating expenses table from lower on the same page of that document:

```

<table>
<colgroup> <col>
<colgroup> <col> <col> <col>
<thead>
<tr> <th>2008 <th>2007 <th>2006
<tbody>
<tr> <th scope=rowgroup> Research and development
<td> $ 1,109 <td> $ 782 <td> $ 712
<tr> <th scope=row> Percentage of net sales
<td> 3.4% <td> 3.3% <td> 3.7%
<tbody>
<tr> <th scope=rowgroup> Selling, general, and administrative
<td> $ 3,761 <td> $ 2,963 <td> $ 2,433
<tr> <th scope=row> Percentage of net sales
<td> 11.6% <td> 12.3% <td> 12.6%
</table>

```

This table could look like this:

	<b>2008</b>	<b>2007</b>	<b>2006</b>
Research and development .....	\$ 1,109	\$ 782	\$ 712
Percentage of net sales .....	3.4%	3.3%	3.7%
Selling, general, and administrative .....	\$ 3,761	\$ 2,963	\$ 2,433
Percentage of net sales .....	11.6%	12.3%	12.6%

Sometimes, tables are used for dense data. For examples, here a table is used to show entries in an access log:

```

<table sortable>
<thead>
<tr>
<th sorted> Timestamp
<th> IP
<th> Message
<tbody>
<tr>
<td> <time>21:01</time>
<td> 128.30.52.199
<td> Exceeded ingress limit
<tr>
<td> <time>21:04</time>
<td> 128.30.52.3
<td> Authentication failure

```

```

<tr>
 <td> <time>22:35</time>
 <td> 128.30.52.29
 <td> Malware command request blocked
<tr>
 <td> <time>22:36</time>
 <td> 128.30.52.3
 <td> Authentication failure
</table>

```

Because the [table<sup>p398</sup>](#) element has a [sortable<sup>p422</sup>](#) attribute, the column headers can be selected to change the table's sort order.

This might render as follows:

Timestamp ▼	IP ▼	Message ▼
21:01	128.30.52.199	Exceeded ingress limit
21:04	128.30.52.3	Authentication failure
22:35	128.30.52.29	Malware command request blocked
22:36	128.30.52.3	Authentication failure

If the user activates the second column, the table might change as follows:

Timestamp ▼	IP ▼	Message ▼
21:04	128.30.52.3	Authentication failure
22:36	128.30.52.3	Authentication failure
22:35	128.30.52.29	Malware command request blocked
21:01	128.30.52.199	Exceeded ingress limit

If the user activates the second column again, reversing the sort order, it might change as follows:

Timestamp ▼	IP ▲	Message ▼
21:01	128.30.52.199	Exceeded ingress limit
22:35	128.30.52.29	Malware command request blocked
21:04	128.30.52.3	Authentication failure
22:36	128.30.52.3	Authentication failure

## 4.10 Forms

### 4.10.1 Introduction

*This section is non-normative.*

A form is a component of a Web page that has form controls, such as text fields, buttons, checkboxes, range controls, or colour pickers, that interact with such a form, providing data that can then be sent to the server for further processing (e.g. returning the results of a search or calculation). No client-side scripting is needed in many cases, though an API is available so that scripts can augment the user experience of forms for purposes other than submitting data to a server.

Writing a form consists of several steps, which can be performed in any order: writing the user interface, implementing the server, and configuring the user interface to communicate with the server.

#### 4.10.1.1 Writing a form's user interface

This section is non-normative.

For the purposes of this brief introduction, we will create a pizza ordering form.

Any form starts with a `form`<sup>p447</sup> element, inside which are placed the controls. Most controls are represented by the `input`<sup>p452</sup> element, which by default provides a one-line text field. To label a control, the `label`<sup>p451</sup> element is used; the label text and the control itself go inside the `label`<sup>p451</sup> element. Each part of a form is considered a `paragraph`<sup>p118</sup>, and is typically separated from other parts using `p`<sup>p187</sup> elements. Putting this together, here is how one might ask for the customer's name:

```
<form>
 <p><label>Customer name: <input></label></p>
</form>
```

To let the user select the size of the pizza, we can use a set of radio buttons. Radio buttons also use the `input`<sup>p452</sup> element, this time with a `type`<sup>p454</sup> attribute with the value `radio`<sup>p475</sup>. To make the radio buttons work as a group, they are given a common name using the `name`<sup>p529</sup> attribute. To group a batch of controls together, such as, in this case, the radio buttons, one can use the `fieldset`<sup>p524</sup> element. The title of such a group of controls is given by the first element in the `fieldset`<sup>p524</sup>, which has to be a `legend`<sup>p526</sup> element.

```
<form>
 <p><label>Customer name: <input></label></p>
 <fieldset>
 <legend> Pizza Size </legend>
 <p><label> <input type=radio name=size> Small </label></p>
 <p><label> <input type=radio name=size> Medium </label></p>
 <p><label> <input type=radio name=size> Large </label></p>
 </fieldset>
</form>
```

**Note** Changes from the previous step are highlighted.

To pick toppings, we can use checkboxes. These use the `input`<sup>p452</sup> element with a `type`<sup>p454</sup> attribute with the value `checkbox`<sup>p475</sup>:

```
<form>
 <p><label>Customer name: <input></label></p>
 <fieldset>
 <legend> Pizza Size </legend>
 <p><label> <input type=radio name=size> Small </label></p>
 <p><label> <input type=radio name=size> Medium </label></p>
 <p><label> <input type=radio name=size> Large </label></p>
 </fieldset>
 <fieldset>
 <legend> Pizza Toppings </legend>
 <p><label> <input type=checkbox> Bacon </label></p>
 <p><label> <input type=checkbox> Extra Cheese </label></p>
 <p><label> <input type=checkbox> Onion </label></p>
 <p><label> <input type=checkbox> Mushroom </label></p>
 </fieldset>
</form>
```

The pizzeria for which this form is being written is always making mistakes, so it needs a way to contact the customer. For this purpose, we can use form controls specifically for telephone numbers (`input`<sup>p452</sup> elements with their `type`<sup>p454</sup> attribute set to `tel`<sup>p459</sup>) and e-mail addresses (`input`<sup>p452</sup> elements with their `type`<sup>p454</sup> attribute set to `email`<sup>p461</sup>):

```
<form>
 <p><label>Customer name: <input></label></p>
 <p><label>Telephone: <input type=tel></label></p>
 <p><label>E-mail address: <input type=email></label></p>
 <fieldset>
 <legend> Pizza Size </legend>
 <p><label> <input type=radio name=size> Small </label></p>
```

```

<p><label> <input type=radio name=size> Medium </label></p>
<p><label> <input type=radio name=size> Large </label></p>
</fieldset>
<fieldset>
<legend> Pizza Toppings </legend>
<p><label> <input type=checkbox> Bacon </label></p>
<p><label> <input type=checkbox> Extra Cheese </label></p>
<p><label> <input type=checkbox> Onion </label></p>
<p><label> <input type=checkbox> Mushroom </label></p>
</fieldset>
</form>

```

We can use an `input`<sup>p452</sup> element with its `type`<sup>p454</sup> attribute set to `time`<sup>p467</sup> to ask for a delivery time. Many of these form controls have attributes to control exactly what values can be specified; in this case, three attributes of particular interest are `min`<sup>p487</sup>, `max`<sup>p487</sup>, and `step`<sup>p488</sup>. These set the minimum time, the maximum time, and the interval between allowed values (in seconds). This pizzeria only delivers between 11am and 9pm, and doesn't promise anything better than 15 minute increments, which we can mark up as follows:

```

<form>
<p><label>Customer name: <input></label></p>
<p><label>Telephone: <input type=tel></label></p>
<p><label>E-mail address: <input type=email></label></p>
<fieldset>
<legend> Pizza Size </legend>
<p><label> <input type=radio name=size> Small </label></p>
<p><label> <input type=radio name=size> Medium </label></p>
<p><label> <input type=radio name=size> Large </label></p>
</fieldset>
<fieldset>
<legend> Pizza Toppings </legend>
<p><label> <input type=checkbox> Bacon </label></p>
<p><label> <input type=checkbox> Extra Cheese </label></p>
<p><label> <input type=checkbox> Onion </label></p>
<p><label> <input type=checkbox> Mushroom </label></p>
</fieldset>
<p><label>Preferred delivery time: <input type=time min="11:00" max="21:00" step="900"></label></p>
</form>

```

The `textarea`<sup>p508</sup> element can be used to provide a free-form text field. In this instance, we are going to use it to provide a space for the customer to give delivery instructions:

```

<form>
<p><label>Customer name: <input></label></p>
<p><label>Telephone: <input type=tel></label></p>
<p><label>E-mail address: <input type=email></label></p>
<fieldset>
<legend> Pizza Size </legend>
<p><label> <input type=radio name=size> Small </label></p>
<p><label> <input type=radio name=size> Medium </label></p>
<p><label> <input type=radio name=size> Large </label></p>
</fieldset>
<fieldset>
<legend> Pizza Toppings </legend>
<p><label> <input type=checkbox> Bacon </label></p>
<p><label> <input type=checkbox> Extra Cheese </label></p>
<p><label> <input type=checkbox> Onion </label></p>
<p><label> <input type=checkbox> Mushroom </label></p>
</fieldset>
<p><label>Preferred delivery time: <input type=time min="11:00" max="21:00" step="900"></label></p>
<p><label>Delivery instructions: <textarea></textarea></label></p>
</form>

```

Finally, to make the form submittable we use the [button<sup>p495</sup>](#) element:

```
<form>
 <p><label>Customer name: <input></label></p>
 <p><label>Telephone: <input type=tel></label></p>
 <p><label>E-mail address: <input type=email></label></p>
 <fieldset>
 <legend> Pizza Size </legend>
 <p><label> <input type=radio name=size> Small </label></p>
 <p><label> <input type=radio name=size> Medium </label></p>
 <p><label> <input type=radio name=size> Large </label></p>
 </fieldset>
 <fieldset>
 <legend> Pizza Toppings </legend>
 <p><label> <input type=checkbox> Bacon </label></p>
 <p><label> <input type=checkbox> Extra Cheese </label></p>
 <p><label> <input type=checkbox> Onion </label></p>
 <p><label> <input type=checkbox> Mushroom </label></p>
 </fieldset>
 <p><label>Preferred delivery time: <input type=time min="11:00" max="21:00" step="900"></label></p>
 <p><label>Delivery instructions: <textarea></textarea></label></p>
 <p><button>Submit order</button></p>
</form>
```

#### 4.10.1.2 Implementing the server-side processing for a form

*This section is non-normative.*

The exact details for writing a server-side processor are out of scope for this specification. For the purposes of this introduction, we will assume that the script at <https://pizza.example.com/order.cgi> is configured to accept submissions using the [application/x-www-form-urlencoded<sup>p532</sup>](#) format, expecting the following parameters sent in an HTTP POST body:

```
custname
 Customer's name

custtel
 Customer's telephone number

custemail
 Customer's e-mail address

size
 The pizza size, either small, medium, or large

topping
 A topping, specified once for each selected topping, with the allowed values being bacon, cheese, onion, and mushroom

delivery
 The requested delivery time

comments
 The delivery instructions
```

#### 4.10.1.3 Configuring a form to communicate with a server

*This section is non-normative.*

Form submissions are exposed to servers in a variety of ways, most commonly as HTTP GET or POST requests. To specify the exact method used, the [method<sup>p531</sup>](#) attribute is specified on the [form<sup>p447</sup>](#) element. This doesn't specify how the form data is encoded, though; to specify that, you

use the `enctype`<sup>p532</sup> attribute. You also have to specify the `URL`<sup>p48</sup> of the service that will handle the submitted data, using the `action`<sup>p531</sup> attribute.

For each form control you want submitted, you then have to give a name that will be used to refer to the data in the submission. We already specified the name for the group of radio buttons; the same attribute (`name`<sup>p529</sup>) also specifies the submission name. Radio buttons can be distinguished from each other in the submission by giving them different values, using the `value`<sup>p457</sup> attribute.

Multiple controls can have the same name; for example, here we give all the checkboxes the same name, and the server distinguishes which checkbox was checked by seeing which values are submitted with that name — like the radio buttons, they are also given unique values with the `value`<sup>p457</sup> attribute.

Given the settings in the previous section, this all becomes:

```
<form method="post"
 enctype="application/x-www-form-urlencoded"
 action="https://pizza.example.com/order.cgi">
 <p><label>Customer name: <input name="custname"></label></p>
 <p><label>Telephone: <input type=tel name="custtel"></label></p>
 <p><label>E-mail address: <input type=email name="custemail"></label></p>
 <fieldset>
 <legend> Pizza Size </legend>
 <p><label> <input type=radio name=size value="small"> Small </label></p>
 <p><label> <input type=radio name=size value="medium"> Medium </label></p>
 <p><label> <input type=radio name=size value="large"> Large </label></p>
 </fieldset>
 <fieldset>
 <legend> Pizza Toppings </legend>
 <p><label> <input type=checkbox name="topping" value="bacon"> Bacon </label></p>
 <p><label> <input type=checkbox name="topping" value="cheese"> Extra Cheese </label></p>
 <p><label> <input type=checkbox name="topping" value="onion"> Onion </label></p>
 <p><label> <input type=checkbox name="topping" value="mushroom"> Mushroom </label></p>
 </fieldset>
 <p><label>Preferred delivery time: <input type=time min="11:00" max="21:00" step="900"
 name="delivery"></label></p>
 <p><label>Delivery instructions: <textarea name="comments"></textarea></label></p>
 <p><button>Submit order</button></p>
</form>
```

**Note** There is no particular significance to the way some of the attributes have their values quoted and others don't. The HTML syntax allows a variety of equally valid ways to specify attributes, as discussed in the syntax section<sup>p944</sup>.

For example, if the customer entered "Denise Lawrence" as their name, "555-321-8642" as their telephone number, did not specify an e-mail address, asked for a medium-sized pizza, selected the Extra Cheese and Mushroom toppings, entered a delivery time of 7pm, and left the delivery instructions text field blank, the user agent would submit the following to the online Web service:

```
custname=Denise+Lawrence&custtel=555-321-8642&custemail=&size=medium&topping=cheese&topping=mushroom&delivery=19%30
```

#### 4.10.1.4 Client-side form validation

This section is non-normative.

Forms can be annotated in such a way that the user agent will check the user's input before the form is submitted. The server still expects the input to be valid (since hostile users can easily bypass the form validation), but it allows the user to avoid the wait incurred by having the user agent be the sole checker of the user's input.

The simplest annotation is the `required`<sup>p484</sup> attribute, which can be specified on `input`<sup>p452</sup> elements to indicate that the form is not to be submitted until a value is given. By adding this attribute to the customer name, pizza size, and delivery time fields, we allow the user agent to tell the user when the user submits the form without filling in those fields:

Support:	
Chrome	10+
IE	10+
Chrome for Android	40+
Firefox	4+
iOS Safari	None
Android Browser	4.4.3-4.4.4+
UC Browser for Android	9.9+
Opera Mini	None
Safari (limited)	5+
Opera	10.0-10.1+
IE Mobile (limited)	10+
Firefox for Android	33+

Source: caniuse.com

```

<form method="post"
 enctype="application/x-www-form-urlencoded"
 action="https://pizza.example.com/order.cgi">
<p><label>Customer name: <input name="custname" required></label></p>
<p><label>Telephone: <input type=tel name="custtel"></label></p>
<p><label>E-mail address: <input type=email name="custemail"></label></p>
<fieldset>
 <legend> Pizza Size </legend>
 <p><label> <input type=radio name=size required value="small"> Small </label></p>
 <p><label> <input type=radio name=size required value="medium"> Medium </label></p>
 <p><label> <input type=radio name=size required value="large"> Large </label></p>
</fieldset>
<fieldset>
 <legend> Pizza Toppings </legend>
 <p><label> <input type=checkbox name="topping" value="bacon"> Bacon </label></p>
 <p><label> <input type=checkbox name="topping" value="cheese"> Extra Cheese </label></p>
 <p><label> <input type=checkbox name="topping" value="onion"> Onion </label></p>
 <p><label> <input type=checkbox name="topping" value="mushroom"> Mushroom </label></p>
</fieldset>
<p><label>Preferred delivery time: <input type=time min="11:00" max="21:00" step="900" name="delivery" required></label></p>
<p><label>Delivery instructions: <textarea name="comments"></textarea></label></p>
<p><button>Submit order</button></p>
</form>

```

It is also possible to limit the length of the input, using the `maxlength`<sup>p529</sup> attribute. By adding this to the `textarea`<sup>p508</sup> element, we can limit users to 1000 characters, preventing them from writing huge essays to the busy delivery drivers instead of staying focused and to the point:

```

<form method="post"
 enctype="application/x-www-form-urlencoded"
 action="https://pizza.example.com/order.cgi">
<p><label>Customer name: <input name="custname" required></label></p>
<p><label>Telephone: <input type=tel name="custtel"></label></p>
<p><label>E-mail address: <input type=email name="custemail"></label></p>
<fieldset>
 <legend> Pizza Size </legend>
 <p><label> <input type=radio name=size required value="small"> Small </label></p>
 <p><label> <input type=radio name=size required value="medium"> Medium </label></p>
 <p><label> <input type=radio name=size required value="large"> Large </label></p>
</fieldset>
<fieldset>
 <legend> Pizza Toppings </legend>
 <p><label> <input type=checkbox name="topping" value="bacon"> Bacon </label></p>
 <p><label> <input type=checkbox name="topping" value="cheese"> Extra Cheese </label></p>
 <p><label> <input type=checkbox name="topping" value="onion"> Onion </label></p>
 <p><label> <input type=checkbox name="topping" value="mushroom"> Mushroom </label></p>
</fieldset>
<p><label>Preferred delivery time: <input type=time min="11:00" max="21:00" step="900" name="delivery" required></label></p>
<p><label>Delivery instructions: <textarea name="comments" maxlength=1000></textarea></label></p>
<p><button>Submit order</button></p>
</form>

```

**Note** When a form is submitted, `invalid`<sup>p1144</sup> events are fired at each form control that is invalid, and then at the `form`<sup>p447</sup> element itself. This can be useful for displaying a summary of the problems with the form, since typically the browser itself will only report one problem at a time.

#### 4.10.1.5 Enabling client-side automatic filling of form controls

*This section is non-normative.*

Some browsers attempt to aid the user by automatically filling form controls rather than having the user reenter their information each time. For example, a field asking for the user's telephone number can be automatically filled with the user's phone number.

To help the user agent with this, the [autocomplete<sup>p535</sup>](#) attribute can be used to describe the field's purpose. In the case of this form, we have three fields that can be usefully annotated in this way: the information about who the pizza is to be delivered to. Adding this information looks like this:

```
<form method="post"
 enctype="application/x-www-form-urlencoded"
 action="https://pizza.example.com/order.cgi">
 <p><label>Customer name: <input name="custname" required autocomplete="shipping name"></label></p>
 <p><label>Telephone: <input type="tel" name="custtel" autocomplete="shipping tel"></label></p>
 <p><label>E-mail address: <input type="email" name="custemail" autocomplete="shipping email"></label></p>
 <fieldset>
 <legend> Pizza Size </legend>
 <p><label> <input type="radio" name="size" required value="small"> Small </label></p>
 <p><label> <input type="radio" name="size" required value="medium"> Medium </label></p>
 <p><label> <input type="radio" name="size" required value="large"> Large </label></p>
 </fieldset>
 <fieldset>
 <legend> Pizza Toppings </legend>
 <p><label> <input type="checkbox" name="topping" value="bacon"> Bacon </label></p>
 <p><label> <input type="checkbox" name="topping" value="cheese"> Extra Cheese </label></p>
 <p><label> <input type="checkbox" name="topping" value="onion"> Onion </label></p>
 <p><label> <input type="checkbox" name="topping" value="mushroom"> Mushroom </label></p>
 </fieldset>
 <p><label>Preferred delivery time: <input type="time" min="11:00" max="21:00" step="900" name="delivery" required></label></p>
 <p><label>Delivery instructions: <textarea name="comments" maxlength=1000></textarea></label></p>
 <p><button>Submit order</button></p>
</form>
```

#### 4.10.1.6 Improving the user experience on mobile devices

*This section is non-normative.*

Some devices, in particular those with on-screen keyboards and those in locales with languages with many characters (e.g. Japanese), can provide the user with multiple input modalities. For example, when typing in a credit card number the user may wish to only see keys for digits 0-9, while when typing in their name they may wish to see a form field that by default capitalises each word.

Using the [inputmode<sup>p534</sup>](#) attribute we can select appropriate input modalities:

```
<form method="post"
 enctype="application/x-www-form-urlencoded"
 action="https://pizza.example.com/order.cgi">
 <p><label>Customer name: <input name="custname" required autocomplete="shipping name"
 inputmode="latin-name"></label></p>
 <p><label>Telephone: <input type="tel" name="custtel" autocomplete="shipping tel"></label></p>
 <p><label>E-mail address: <input type="email" name="custemail" autocomplete="shipping email"></label></p>
 <fieldset>
 <legend> Pizza Size </legend>
 <p><label> <input type="radio" name="size" required value="small"> Small </label></p>
 <p><label> <input type="radio" name="size" required value="medium"> Medium </label></p>
 <p><label> <input type="radio" name="size" required value="large"> Large </label></p>
 </fieldset>
 <fieldset>
```

```

<legend> Pizza Toppings </legend>
<p><label> <input type=checkbox name="topping" value="bacon"> Bacon </label></p>
<p><label> <input type=checkbox name="topping" value="cheese"> Extra Cheese </label></p>
<p><label> <input type=checkbox name="topping" value="onion"> Onion </label></p>
<p><label> <input type=checkbox name="topping" value="mushroom"> Mushroom </label></p>
</fieldset>
<p><label>Preferred delivery time: <input type=time min="11:00" max="21:00" step="900" name="delivery" required></label></p>
<p><label>Delivery instructions: <textarea name="comments" maxlength=1000 inputmode="latin-prose"></textarea></label></p>
<p><button>Submit order</button></p>
</form>

```

#### 4.10.1.7 The difference between the field type, the autofocus field name, and the input modality

*This section is non-normative.*

The `type`<sup>p454</sup>, `autocomplete`<sup>p535</sup>, and `inputmode`<sup>p534</sup> attributes can seem confusingly similar. For instance, in all three cases, the string "email" is a valid value. This section attempts to illustrate the difference between the three attributes and provides advice suggesting how to use them.

The `type`<sup>p454</sup> attribute on `input`<sup>p452</sup> elements decides what kind of control the user agent will use to expose the field. Choosing between different values of this attribute is the same choice as choosing whether to use an `input`<sup>p452</sup> element, a `textarea`<sup>p508</sup> element, a `select`<sup>p498</sup> element, a `keygen`<sup>p513</sup> element, etc.

The `autocomplete`<sup>p535</sup> attribute, in contrast, describes what the value that the user will enter actually represents. Choosing between different values of this attribute is the same choice as choosing what the label for the element will be.

First, consider telephone numbers. If a page is asking for a telephone number from the user, the right form control to use is `<input type=tel>`<sup>p459</sup>. However, which `autocomplete`<sup>p535</sup> value to use depends on which phone number the page is asking for, whether they expect a telephone number in the international format or just the local format, and so forth.

For example, a page that forms part of a checkout process on an e-commerce site for a customer buying a gift to be shipped to a friend might need both the buyer's telephone number (in case of payment issues) and the friend's telephone number (in case of delivery issues). If the site expects international phone numbers (with the country code prefix), this could thus look like this:

```

<p><label>Your phone number: <input type=tel name=custtel autocomplete="billing tel"></label>
<p><label>Recipient's phone number: <input type=tel name=shiptel autocomplete="shipping tel"></label>
<p>Please enter complete phone numbers including the country code prefix, as in "+1 555 123 4567".

```

But if the site only supports British customers and recipients, it might instead look like this (notice the use of `tel-national`<sup>p539</sup> rather than `tel`<sup>p539</sup>):

```

<p><label>Your phone number: <input type=tel name=custtel autocomplete="billing tel-national"></label>
<p><label>Recipient's phone number: <input type=tel name=shiptel autocomplete="shipping tel-national"></label>
<p>Please enter complete UK phone numbers, as in "(01632) 960 123".

```

Now, consider a person's preferred languages. The right `autocomplete`<sup>p535</sup> value is `language`<sup>p538</sup>. However, there could be a number of different form controls used for the purpose: a free text field (`<input type=text>`<sup>p458</sup>), a drop-down list (`<select>`<sup>p498</sup>), radio buttons (`<input type=radio>`<sup>p475</sup>), etc. It only depends on what kind of interface is desired.

The `inputmode`<sup>p534</sup> decides what kind of input modality (e.g. keyboard) to use, when the control is a free-form text field.

Consider names. If a page just wants one name from the user, then the relevant control is `<input type=text>`<sup>p458</sup>. If the page is asking for the user's full name, then the relevant `autocomplete`<sup>p535</sup> value is `name`<sup>p537</sup>. But if the user is Japanese, and the page is asking for the user's Japanese name and the user's romanised name, then it would be helpful to the user if the first field defaulted to a Japanese input modality, while the second defaulted to a Latin input modality (ideally with automatic capitalization of each word). This is where the `inputmode`<sup>p534</sup> attribute can help:

```
<p><label>Japanese name: <input name="j" type="text" autocomplete="section-jp name" inputmode="kana"></label>
<label>Romanised name: <input name="e" type="text" autocomplete="section-en name" inputmode="latin-name"></label>
```

In this example, the "[section-\\*<sup>p535</sup>](#)" keywords in the [autocomplete<sup>p535</sup>](#) attributes' values tell the user agent that the two fields expect *different* names. Without them, the user agent could automatically fill the second field with the value given in the first field when the user gave a value to the first field.

**Note** *The "-jp" and "-en" parts of the keywords are opaque to the user agent; the user agent cannot guess, from those, that the two names are expected to be in Japanese and English respectively.*

#### 4.10.1.8 Date, time, and number formats

*This section is non-normative.*

In this pizza delivery example, the times are specified in the format "HH:MM": two digits for the hour, in 24-hour format, and two digits for the time. (Seconds could also be specified, though they are not necessary in this example.)

In some locales, however, times are often expressed differently when presented to users. For example, in the United States, it is still common to use the 12-hour clock with an am/pm indicator, as in "2pm". In France, it is common to separate the hours from the minutes using an "h" character, as in "14h00".

Similar issues exist with dates, with the added complication that even the order of the components is not always consistent — for example, in Cyprus the first of February 2003 would typically be written "1/2/03", while that same date in Japan would typically be written as "2003年02月01日" — and even with numbers, where locales differ, for example, in what punctuation is used as the decimal separator and the thousands separator.

It is therefore important to distinguish the time, date, and number formats used in HTML and in form submissions, which are always the formats defined in this specification (and based on the well-established ISO 8601 standard for computer-readable date and time formats), from the time, date, and number formats presented to the user by the browser and accepted as input from the user by the browser.

The format used "on the wire", i.e. in HTML markup and in form submissions, is intended to be computer-readable and consistent irrespective of the user's locale. Dates, for instance, are always written in the format "YYYY-MM-DD", as in "2003-02-01". Users are not expected to ever see this format.

The time, date, or number given by the page in the wire format is then translated to the user's preferred presentation (based on user preferences or on the locale of the page itself), before being displayed to the user. Similarly, after the user inputs a time, date, or number using their preferred format, the user agent converts it back to the wire format before putting it in the DOM or submitting it.

This allows scripts in pages and on servers to process times, dates, and numbers in a consistent manner without needing to support dozens of different formats, while still supporting the users' needs.

**Note** *See also the [implementation notes<sup>p482</sup>](#) regarding localization of form controls.*

#### 4.10.2 Categories

Mostly for historical reasons, elements in this section fall into several overlapping (but subtly different) categories in addition to the usual ones like [flow content<sup>p115</sup>](#), [phrasing content<sup>b116</sup>](#), and [interactive content<sup>p116</sup>](#).

A number of the elements are **form-associated elements**, which means they can have a [form owner<sup>p527</sup>](#).

⇒ [button<sup>p495</sup>](#), [fieldset<sup>p524</sup>](#), [input<sup>p452</sup>](#), [keygen<sup>p513</sup>](#), [label<sup>p451</sup>](#), [object<sup>p310</sup>](#), [output<sup>p516</sup>](#), [select<sup>p498</sup>](#), [textarea<sup>p508</sup>](#), [img<sup>p272</sup>](#)

The [form-associated elements<sup>p446</sup>](#) fall into several subcategories:

##### Listed elements

Denotes elements that are listed in the [form.elements<sup>p449</sup>](#) and [fieldset.elements<sup>p525</sup>](#) APIs.

⇒ [button<sup>p495</sup>](#), [fieldset<sup>p524</sup>](#), [input<sup>p452</sup>](#), [keygen<sup>p513</sup>](#), [object<sup>p310</sup>](#), [output<sup>p516</sup>](#), [select<sup>p498</sup>](#), [textarea<sup>p508</sup>](#)

## Submittable elements

Denotes elements that can be used for [constructing the form data set](#)<sup>p561</sup> when a [form](#)<sup>p447</sup> element is [submitted](#)<sup>p558</sup>.

⇒ [button](#)<sup>p495</sup>, [input](#)<sup>p452</sup>, [keygen](#)<sup>p513</sup>, [object](#)<sup>p310</sup>, [select](#)<sup>p498</sup>, [textarea](#)<sup>p508</sup>

Some [submittable elements](#)<sup>p447</sup> can be, depending on their attributes, **buttons**. The prose below defines when an element is a button. Some buttons are specifically **submit buttons**.

## Resettable elements

Denotes elements that can be affected when a [form](#)<sup>p447</sup> element is [reset](#)<sup>p567</sup>.

⇒ [input](#)<sup>p452</sup>, [keygen](#)<sup>p513</sup>, [output](#)<sup>p516</sup>, [select](#)<sup>p498</sup>, [textarea](#)<sup>p508</sup>

## Reassociateable elements

Denotes elements that have a [form](#)<sup>p527</sup> content attribute, and a matching [form](#)<sup>p529</sup> IDL attribute, that allow authors to specify an explicit [form owner](#)<sup>p527</sup>.

⇒ [button](#)<sup>p495</sup>, [fieldset](#)<sup>p524</sup>, [input](#)<sup>p452</sup>, [keygen](#)<sup>p513</sup>, [label](#)<sup>p451</sup>, [object](#)<sup>p310</sup>, [output](#)<sup>p516</sup>, [select](#)<sup>p498</sup>, [textarea](#)<sup>p508</sup>

Some elements, not all of them [form-associated](#)<sup>p446</sup>, are categorised as **labelable elements**. These are elements that can be associated with a [label](#)<sup>p451</sup> element.

⇒ [button](#)<sup>p495</sup>, [input](#)<sup>p452</sup> (if the [type](#)<sup>p454</sup> attribute is *not* in the [hidden](#)<sup>p458</sup> state), [keygen](#)<sup>p513</sup>, [meter](#)<sup>p519</sup>, [output](#)<sup>p516</sup>, [progress](#)<sup>p518</sup>, [select](#)<sup>p498</sup>, [textarea](#)<sup>p508</sup>

## 4.10.3 The [form](#) element

Spec bugs: [22320](#), [27833](#)

Categories<sup>p113</sup>:

[Flow content](#)<sup>p115</sup>.  
[Palpable content](#)<sup>p117</sup>.

Contexts in which this element can be used<sup>p113</sup>:

Where [flow content](#)<sup>p115</sup> is expected.

Content model<sup>p113</sup>:

[Flow content](#)<sup>p115</sup>, but with no [form](#)<sup>p447</sup> element descendants.

Tag omission in text/html<sup>p113</sup>:

Neither tag is omissible.

Content attributes<sup>p113</sup>:

[Global attributes](#)<sup>p120</sup>  
[accept-charset](#)<sup>p448</sup> — Character encodings to use for [form submission](#)<sup>p557</sup>  
[action](#)<sup>p531</sup> — [URL](#)<sup>p48</sup> to use for [form submission](#)<sup>p557</sup>  
[autocomplete](#)<sup>p448</sup> — Default setting for autofill feature for controls in the form  
[enctype](#)<sup>p532</sup> — Form data set encoding type to use for [form submission](#)<sup>p557</sup>  
[method](#)<sup>p531</sup> — HTTP method to use for [form submission](#)<sup>p557</sup>  
[name](#)<sup>p448</sup> — Name of form to use in the [document.forms](#)<sup>p107</sup> API  
[novalidate](#)<sup>p532</sup> — Bypass form control validation for [form submission](#)<sup>p557</sup>  
[target](#)<sup>p532</sup> — [Browsing context](#)<sup>p762</sup> for [form submission](#)<sup>p557</sup>

DOM interface<sup>p113</sup>:

IDL	[OverrideBuiltins] interface <a href="#">HTMLFormElement</a> : <a href="#">HTMLElement</a> { attribute DOMString <a href="#">acceptCharset</a> ; attribute DOMString <a href="#">action</a> ; attribute DOMString <a href="#">autocomplete</a> ; attribute DOMString <a href="#">enctype</a> ; attribute DOMString <a href="#">encoding</a> ;
-----	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

```

attribute DOMString method;
attribute DOMString name;
attribute boolean noValidate;
attribute DOMString target;

readonly attribute HTMLFormControlsCollection elements;
readonly attribute long length;
getter Element (unsigned long index);
getter (RadioNodeList or Element) (DOMString name);

void submit();
void reset();
boolean checkValidity();
boolean reportValidity();

void requestAutocomplete();
};

```

The form<sup>p447</sup> element represents<sup>b111</sup> a collection of form-associated elements<sup>p446</sup>, some of which can represent editable values that can be submitted to a server for processing.

The accept-charset attribute gives the character encodings that are to be used for the submission. If specified, the value must be an ordered set of unique space-separated tokens<sup>p80</sup> that are ASCII case-insensitive<sup>p58</sup>, and each token must be an ASCII case-insensitive<sup>p58</sup> match for one of the labels<sup>p44</sup> of an ASCII-compatible character encoding<sup>p44</sup>. [ENCODING]<sup>p1150</sup>

The name attribute represents the form<sup>p447</sup>'s name within the forms<sup>p107</sup> collection. The value must not be the empty string, and the value must be unique amongst the form<sup>p447</sup> elements in the forms<sup>p107</sup> collection that it is in, if any.

The autocomplete attribute is an enumerated attribute<sup>p60</sup>. The attribute has two states. The on keyword maps to the on state, and the off keyword maps to the off state. The attribute may also be omitted. The missing value default<sup>p60</sup> is the on<sup>p448</sup> state. The off<sup>p448</sup> state indicates that by default, form controls in the form will have their autofill field name<sup>b540</sup> set to "off<sup>p536</sup>"; the on<sup>p448</sup> state indicates that by default, form controls in the form will have their autofill field name<sup>b540</sup> set to "on<sup>p537</sup>".

The action<sup>b531</sup>, enctype<sup>p532</sup>, method<sup>p531</sup>, novalidate<sup>p532</sup>, and target<sup>p532</sup> attributes are attributes for form submission<sup>p531</sup>.

### Note

**form.elements**<sup>p449</sup>

Returns an HTMLFormControlsCollection<sup>p91</sup> of the form controls in the form (excluding image buttons for historical reasons).

**form.length**<sup>p449</sup>

Returns the number of form controls in the form (excluding image buttons for historical reasons).

**form[index]**

Returns the *index*th element in the form (excluding image buttons for historical reasons).

**form[name]**

Returns the form control (or, if there are several, a RadioNodeList<sup>p92</sup> of the form controls) in the form with the given ID<sup>p51</sup> or name<sup>p529</sup> (excluding image buttons for historical reasons); or, if there are none, returns the img<sup>p272</sup> element with the given ID.

Once an element has been referenced using a particular name, that name will continue being available as a way to reference that element in this method, even if the element's actual ID<sup>p51</sup> or name<sup>p529</sup> changes, for as long as the element remains in the Document<sup>p102</sup>.

If there are multiple matching items, then a RadioNodeList<sup>p92</sup> object containing all those elements is returned.

**form.submit**<sup>p450</sup>()

Submits the form.

`form.resetp450()`

Resets the form.

`form.checkValidityp450()`

Returns true if the form's controls are all valid; otherwise, returns false.

`form.reportValidityp450()`

Returns true if the form's controls are all valid; otherwise, returns false and informs the user.

`form.requestAutocompletep547()`

Triggers a user-agent-specific user interface to help the user fill in any fields that have an `autocomplete` IDL attribute other than "`on`" or "`off`".

The `form` element will subsequently receive an event, either `autocomplete`, indicating that the fields have been prefilled, or `autocompleteerror` (using the `AutocompleteErrorEvent` interface), indicating that there was some problem (the general class of problem is described by the `reason` IDL attribute on the event).

The `autocomplete` IDL attribute must `reflect` the `content` attribute of the same name, [limited to only known values](#).

The `requestAutocomplete()` method is part of the [autofill mechanism](#).

The `name` IDL attribute must `reflect` the `content` attribute of the same name.

The `acceptCharset` IDL attribute must `reflect` the `accept-charset` content attribute.

The `elements` IDL attribute must return an `HTMLFormControlsCollection` rooted at the `form` element's `home subtree`'s `root element`, whose filter matches `listed elements` whose `form owner` is the `form` element, with the exception of `input` elements whose `type` attribute is in the `Image Button` state, which must, for historical reasons, be excluded from this particular collection.

The `length` IDL attribute must return the number of nodes `represented` by the `elements` collection.

The `supported property indices` at any instant are the indices supported by the `elements` attribute at that instant.

When a `form` element is **indexed for indexed property retrieval**, the user agent must return the value returned by the `item` method on the `elements` collection, when invoked with the given index as its argument.

Each `form` element has a mapping of names to elements called the **past names map**. It is used to persist names of controls even when they change names.

The `supported property names` consist of the names obtained from the following algorithm, in the order obtained from this algorithm:

1. Let `sourced names` be an initially empty ordered list of tuples consisting of a string, an element, a source, where the source is either `id`, `name`, or `past`, and, if the source is `past`, an age.
2. For each `listed element` `candidate` whose `form owner` is the `form` element, with the exception of any `input` elements whose `type` attribute is in the `Image Button` state, run these substeps:
  1. If `candidate` has an `id` attribute, add an entry to `sourced names` with that `id` attribute's value as the string, `candidate` as the element, and `id` as the source.
  2. If `candidate` has a `name` attribute, add an entry to `sourced names` with that `name` attribute's value as the string, `candidate` as the element, and `name` as the source.
3. For each `img` element `candidate` whose `form owner` is the `form` element, run these substeps:
  1. If `candidate` has an `id` attribute, add an entry to `sourced names` with that `id` attribute's value as the string, `candidate` as the element, and `id` as the source.

2. If *candidate* has a `name`<sup>p1097</sup> attribute, add an entry to *sourced names* with that `name`<sup>p1097</sup> attribute's value as the string, *candidate* as the element, and *name* as the source.
4. For each entry *past entry* in the `past names map`<sup>p449</sup> add an entry to *sourced names* with the *past entry*'s name as the string, *past entry*'s element as the element, *past* as the source, and the length of time *past entry* has been in the `past names map`<sup>p449</sup> as the age.
5. Sort *sourced names* by `tree order`<sup>p42</sup> of the element entry of each tuple, sorting entries with the same element by putting entries whose source is *id* first, then entries whose source is *name*, and finally entries whose source is *past*, and sorting entries with the same element and source by their age, oldest first.
6. Remove any entries in *sourced names* that have the empty string as their name.
7. Remove any entries in *sourced names* that have the same name as an earlier entry in the map.
8. Return the list of names from *sourced names*, maintaining their relative order.

The properties exposed in this way must be `unenumerable`<sup>p49</sup>.

When a `form`<sup>p447</sup> element is **indexed for named property retrieval**, the user agent must run the following steps:

1. Let *candidates* be a `live`<sup>p43</sup> `RadioNodeList`<sup>b92</sup> object containing all the `listed elements`<sup>p446</sup> whose `form owner`<sup>p527</sup> is the `form`<sup>p447</sup> element that have either an `id`<sup>p122</sup> attribute or a `name`<sup>p529</sup> attribute equal to *name*, with the exception of `input`<sup>p452</sup> elements whose `type`<sup>p454</sup> attribute is in the `Image Button`<sup>p479</sup> state, in `tree order`<sup>p42</sup>.
2. If *candidates* is empty, let *candidates* be a `live`<sup>p43</sup> `RadioNodeList`<sup>b92</sup> object containing all the `img`<sup>p272</sup> elements that are descendants of the `form`<sup>p447</sup> element and that have either an `id`<sup>p122</sup> attribute or a `name`<sup>p1097</sup> attribute equal to *name*, in `tree order`<sup>p42</sup>.
3. If *candidates* is empty, *name* is the name of one of the entries in the `form`<sup>p447</sup> element's `past names map`<sup>p449</sup>: return the object associated with *name* in that map.
4. If *candidates* contains more than one node, return *candidates* and abort these steps.
5. Otherwise, *candidates* contains exactly one node. Add a mapping from *name* to the node in *candidates* in the `form`<sup>p447</sup> element's `past names map`<sup>p449</sup>, replacing the previous entry with the same name, if any.
6. Return the node in *candidates*.

If an element listed in a `form`<sup>p447</sup> element's `past names map`<sup>p449</sup> changes `form owner`<sup>p527</sup>, then its entries must be removed from that map.

The `submit()` method, when invoked, must `submit`<sup>p558</sup> the `form`<sup>p447</sup> element from the `Form`<sup>p447</sup> element itself, with the `submitted from submit()`<sup>p450</sup> method flag set.

The `reset()` method, when invoked, must run the following steps:

1. If the `form`<sup>p447</sup> element is marked as `locked for reset`<sup>p450</sup>, then abort these steps.
2. Mark the `form`<sup>p447</sup> element as **locked for reset**.
3. `Reset`<sup>b567</sup> the `form`<sup>p447</sup> element.
4. Unmark the `form`<sup>p447</sup> element as `locked for reset`<sup>p450</sup>.

If the `checkValidity()` method is invoked, the user agent must `statically validate the constraints`<sup>p554</sup> of the `form`<sup>p447</sup> element, and return true if the constraint validation return a *positive* result, and false if it returned a *negative* result.

If the `reportValidity()` method is invoked, the user agent must `interactively validate the constraints`<sup>p554</sup> of the `form`<sup>p447</sup> element, and return true if the constraint validation return a *positive* result, and false if it returned a *negative* result.

### Example

This example shows two search forms:

```
<form action="http://www.google.com/search" method="get">
 <label>Google: <input type="search" name="q"></label> <input type="submit" value="Search... ">
</form>
```

```
<form action="http://www.bing.com/search" method="get">
 <label>Bing: <input type="search" name="q"></label> <input type="submit" value="Search...">
</form>
```

#### 4.10.4 The `label` element

Spec bugs: [23561](#)

- [Palpable content](#)<sup>p117</sup>.

**Contexts in which this element can be used**<sup>p113</sup>:

Where [phrasing content](#)<sup>p116</sup> is expected.

**Content model**<sup>p113</sup>:

[Phrasing content](#)<sup>p116</sup>, but with no descendant [labelable elements](#)<sup>p447</sup> unless it is the element's [labeled control](#)<sup>p451</sup>, and no descendant [label](#)<sup>p451</sup> elements.

**Tag omission in text/html**<sup>p113</sup>:

Neither tag is omissible.

**Content attributes**<sup>p113</sup>:

- [Global attributes](#)<sup>p120</sup>
- [form](#)<sup>p527</sup> — Associates the control with a [form](#)<sup>p447</sup> element
- [for](#)<sup>p451</sup> — Associate the label with form control

**DOM interface**<sup>p113</sup>:

IDL	<pre>interface HTMLLabelElement : HTMLElement {   readonly attribute HTMLFormElement? form;   attribute DOMString htmlFor;   readonly attribute HTMLElement? control; };</pre>
-----	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

The [label](#)<sup>p451</sup> element [represents](#)<sup>p111</sup> a caption in a user interface. The caption can be associated with a specific form control, known as the [label](#)<sup>p451</sup> element's [labeled control](#), either using the [for](#)<sup>p451</sup> attribute, or by putting the form control inside the [label](#)<sup>p451</sup> element itself.

Except where otherwise specified by the following rules, a [label](#)<sup>p451</sup> element has no [labeled control](#)<sup>p451</sup>.

The [for](#) attribute may be specified to indicate a form control with which the caption is to be associated. If the attribute is specified, the attribute's value must be the [ID](#)<sup>p51</sup> of a [labelable element](#)<sup>p447</sup> in the same [Document](#)<sup>p102</sup> as the [label](#)<sup>p451</sup> element. If the attribute is specified and there is an element in the [Document](#)<sup>p102</sup> whose [ID](#)<sup>p51</sup> is equal to the value of the [for](#)<sup>p451</sup> attribute, and the first such element is a [labelable element](#)<sup>p447</sup>, then that element is the [label](#)<sup>p451</sup> element's [labeled control](#)<sup>p451</sup>.

If the [for](#)<sup>p451</sup> attribute is not specified, but the [label](#)<sup>p451</sup> element has a [labelable element](#)<sup>p447</sup> descendant, then the first such descendant in [tree order](#)<sup>p42</sup> is the [label](#)<sup>p451</sup> element's [labeled control](#)<sup>p451</sup>.

The [label](#)<sup>p451</sup> element's exact default presentation and behaviour, in particular what its [activation behaviour](#)<sup>p725</sup> might be, if anything, should match the platform's label behaviour. The [activation behaviour](#)<sup>p725</sup> of a [label](#)<sup>p451</sup> element for events targeted at [interactive content](#)<sup>p116</sup> descendants of a [label](#)<sup>p451</sup> element, and any descendants of those [interactive content](#)<sup>p116</sup> descendants, must be to do nothing.

#### Example

For example, on platforms where clicking a checkbox label checks the checkbox, clicking the [label](#)<sup>p451</sup> in the following snippet could trigger the user agent to [run synthetic click activation steps](#)<sup>p724</sup> on the [input](#)<sup>p452</sup> element, as if the element itself had been triggered by the user:

```
<label><input type=checkbox name=lost> Lost</label>
```

On other platforms, the behaviour might be just to focus the control, or do nothing.

The `form`<sup>p527</sup> attribute is used to explicitly associate the `label`<sup>p451</sup> element with its `form owner`<sup>p527</sup>.

### Example

The following example shows three form controls each with a label, two of which have small text showing the right format for users to use.

```
<p><label>Full name: <input name=fn> <small>Format: First Last</small></label></p>
<p><label>Age: <input name=age type=number min=0></label></p>
<p><label>Post code: <input name=pc> <small>Format: AB12 3CD</small></label></p>
```

### Note

`label.control`<sup>p452</sup>

Returns the form control that is associated with this element.

The `htmlFor` IDL attribute must `reflect`<sup>p88</sup> the `for`<sup>p451</sup> content attribute.

The `control` IDL attribute must return the `label`<sup>p451</sup> element's `labeled control`<sup>p451</sup>, if any, or null if there isn't one.

The `form`<sup>p529</sup> IDL attribute is part of the element's forms API.

### Note

`control.labels`<sup>p452</sup>

Returns a `NodeList`<sup>p51</sup> of all the `label`<sup>p451</sup> elements that the form control is associated with.

`Labelable elements`<sup>p447</sup> have a `NodeList`<sup>p51</sup> object associated with them that represents the list of `label`<sup>p451</sup> elements, in `tree order`<sup>p42</sup>, whose `labeled control`<sup>p451</sup> is the element in question. The `labels` IDL attribute of `labelable elements`<sup>p447</sup>, on getting, must return that `NodeList`<sup>p51</sup> object.

## 4.10.5 The `input` element

**Categories**<sup>p113</sup>:

`Flow content`<sup>p115</sup>.

`Phrasing content`<sup>p116</sup>.

If the `type`<sup>p454</sup> attribute is not in the `Hidden`<sup>p458</sup> state: `Interactive content`<sup>p116</sup>.

If the `type`<sup>p454</sup> attribute is not in the `Hidden`<sup>p458</sup> state: `Listed`<sup>p446</sup>, `labelable`<sup>p447</sup>, `submittable`<sup>p447</sup>, `resettable`<sup>p447</sup>, and `reassociateable`<sup>p447</sup> `form-associated element`<sup>p446</sup>.

If the `type`<sup>p454</sup> attribute is in the `Hidden`<sup>p458</sup> state: `Listed`<sup>p446</sup>, `submittable`<sup>p447</sup>, `resettable`<sup>p447</sup>, and `reassociateable`<sup>p447</sup> `form-associated element`<sup>p446</sup>.

If the `type`<sup>p454</sup> attribute is not in the `Hidden`<sup>p458</sup> state: `Palpable content`<sup>p117</sup>.

**Contexts in which this element can be used**<sup>p113</sup>:

Where `phrasing content`<sup>p116</sup> is expected.

**Content model**<sup>p113</sup>:

`Nothing`<sup>p114</sup>.

**Tag omission in text/html**<sup>p113</sup>:

No `end tag`<sup>p944</sup>.

**Content attributes**<sup>p113</sup>:

`Global attributes`<sup>p120</sup>

`accept`<sup>p477</sup> — Hint for expected file type in `file upload controls`<sup>p476</sup>

`alt`<sup>p480</sup> — Replacement text for use when images are not available

`autocomplete`<sup>p535</sup> — Hint for form autofill feature

[autofocus](#)<sup>p533</sup> — Automatically focus the form control when the page is loaded  
[checked](#)<sup>p457</sup> — Whether the command or control is checked  
[dirname](#)<sup>p529</sup> — Name of form field to use for sending the element's [directionality](#)<sup>p125</sup> in [form submission](#)<sup>p557</sup>  
[disabled](#)<sup>p530</sup> — Whether the form control is disabled  
[form](#)<sup>p527</sup> — Associates the control with a [form](#)<sup>p447</sup> element  
[formaction](#)<sup>p531</sup> — [URL](#)<sup>p48</sup> to use for [form submission](#)<sup>p557</sup>  
[formenctype](#)<sup>p532</sup> — Form data set encoding type to use for [form submission](#)<sup>p557</sup>  
[formmethod](#)<sup>p531</sup> — HTTP method to use for [form submission](#)<sup>p557</sup>  
[formnovalidate](#)<sup>p532</sup> — Bypass form control validation for [form submission](#)<sup>p557</sup>  
[formtarget](#)<sup>p532</sup> — [Browsing context](#)<sup>p762</sup> for [form submission](#)<sup>p557</sup>  
[height](#)<sup>p397</sup> — Vertical dimension  
[inputmode](#)<sup>p534</sup> — Hint for selecting an input modality  
[list](#)<sup>p489</sup> — List of autocomplete options  
[max](#)<sup>p487</sup> — Maximum value  
[maxlength](#)<sup>p483</sup> — Maximum length of value  
[min](#)<sup>p487</sup> — Minimum value  
[minlength](#)<sup>p483</sup> — Minimum length of value  
[multiple](#)<sup>p485</sup> — Whether to allow multiple values  
[name](#)<sup>p529</sup> — Name of form control to use for [form submission](#)<sup>p557</sup> and in the [form.elements](#)<sup>p449</sup> API  
[pattern](#)<sup>p486</sup> — Pattern to be matched by the form control's value  
[placeholder](#)<sup>p490</sup> — User-visible label to be placed within the form control  
[readonly](#)<sup>p483</sup> — Whether to allow the value to be edited by the user  
[required](#)<sup>p484</sup> — Whether the control is required for [form submission](#)<sup>p557</sup>  
[size](#)<sup>p483</sup> — Size of the control  
[src](#)<sup>p479</sup> — Address of the resource  
[step](#)<sup>p488</sup> — Granularity to be matched by the form control's value  
[type](#)<sup>p454</sup> — Type of form control  
[value](#)<sup>p457</sup> — Value of the form control  
[width](#)<sup>p397</sup> — Horizontal dimension

Also, the [title](#)<sup>p486</sup> attribute [has special semantics](#)<sup>p486</sup> on this element: Description of pattern (when used with [pattern](#)<sup>p486</sup> attribute).

#### DOM interface<sup>p113</sup>:

IDL	<pre>interface <b>HTMLInputElement</b> : <b>HTMLElement</b> {   attribute DOMString <u><a href="#">accept</a></u>;   attribute DOMString <u><a href="#">alt</a></u>;   attribute DOMString <u><a href="#">autocomplete</a></u>;   attribute boolean <u><a href="#">autofocus</a></u>;   attribute boolean <u><a href="#">defaultChecked</a></u>;   attribute boolean <u><a href="#">checked</a></u>;   attribute DOMString <u><a href="#">dirName</a></u>;   attribute boolean <u><a href="#">disabled</a></u>;   readonly attribute <u><a href="#">HTMLFormElement</a></u>? <u><a href="#">form</a></u>;   readonly attribute <u><a href="#">FileList</a></u>? <u><a href="#">files</a></u>;   attribute DOMString <u><a href="#">formAction</a></u>;   attribute DOMString <u><a href="#">formEnctype</a></u>;   attribute DOMString <u><a href="#">formMethod</a></u>;   attribute boolean <u><a href="#">formNoValidate</a></u>;   attribute DOMString <u><a href="#">formTarget</a></u>;   attribute unsigned long <u><a href="#">height</a></u>;   attribute boolean <u><a href="#">indeterminate</a></u>;   attribute DOMString <u><a href="#">inputMode</a></u>;   readonly attribute <u><a href="#">HTMLElement</a></u>? <u><a href="#">list</a></u>;   attribute DOMString <u><a href="#">max</a></u>;   attribute long <u><a href="#">maxLength</a></u>;   attribute DOMString <u><a href="#">min</a></u>;   attribute long <u><a href="#">minLength</a></u>;</pre>

direction);

// also has obsolete members
};

```

The [input](#)<sup>p452</sup> element [represents](#)<sup>p111</sup> a typed data field, usually with a form control to allow the user to edit the data.

The **type** attribute controls the data type (and associated control) of the element. It is an [enumerated attribute](#)<sup>p60</sup>. The following table lists the keywords and states for the attribute — the keywords in the left column map to the states in the cell in the second column on the same row as the keyword.

Keyword	State	Data type	Control type
<b>hidden</b>	<u><a href="#">Hidden</a></u> <sup>p458</sup>	An arbitrary string	n/a
<b>text</b>	<u><a href="#">Text</a></u> <sup>p458</sup>	Text with no line breaks	A text field
<b>search</b>	<u><a href="#">Search</a></u> <sup>p458</sup>	Text with no line breaks	Search field
<b>tel</b>	<u><a href="#">Telephone</a></u> <sup>p459</sup>	Text with no line breaks	A text field
<b>url</b>	<u><a href="#">URL</a></u> <sup>p460</sup>	An absolute URL	A text field
<b>email</b>	<u><a href="#">E-mail</a></u> <sup>p461</sup>	An e-mail address or list of e-mail addresses	A text field

Keyword	State	Data type	Control type
password	Password <sup>p462</sup>	Text with no line breaks (sensitive information)	A text field that obscures data entry
datetime	Date and Time <sup>p463</sup>	A date and time (year, month, day, hour, minute, second, fraction of a second) with the time zone set to UTC	A date and time control
date	Date <sup>p464</sup>	A date (year, month, day) with no time zone	A date control
month	Month <sup>p465</sup>	A date consisting of a year and a month with no time zone	A month control
week	Week <sup>p466</sup>	A date consisting of a week-year number and a week number with no time zone	A week control
time	Time <sup>p467</sup>	A time (hour, minute, seconds, fractional seconds) with no time zone	A time control
datetime-local	Local Date and Time <sup>p468</sup>	A date and time (year, month, day, hour, minute, second, fraction of a second) with no time zone	A date and time control
number	Number <sup>p469</sup>	A numerical value	A text field or spinner control
range	Range <sup>p470</sup>	A numerical value, with the extra semantic that the exact value is not important	A slider control or similar
color	Colour <sup>p474</sup>	An sRGB colour with 8-bit red, green, and blue components	A colour well
checkbox	Checkbox <sup>p475</sup>	A set of zero or more values from a predefined list	A checkbox
radio	Radio Button <sup>p475</sup>	An enumerated value	A radio button
file	File Upload <sup>p476</sup>	Zero or more files each with a <a href="#">MIME type<sup>p42</sup></a> and optionally a file name	A label and a button
submit	Submit Button <sup>p478</sup>	An enumerated value, with the extra semantic that it must be the last value selected and initiates form submission	A button
image	Image Button <sup>p479</sup>	A coordinate, relative to a particular image's size, with the extra semantic that it must be the last value selected and initiates form submission	Either a clickable image, or a button
reset	Reset Button <sup>p481</sup>	n/a	A button
button	Button <sup>p482</sup>	n/a	A button

The [missing value default<sup>p60</sup>](#) is the [Text<sup>p458</sup>](#) state.

Which of the [accept<sup>p477</sup>](#), [alt<sup>p480</sup>](#), [autocomplete<sup>p535</sup>](#), [checked<sup>p457</sup>](#), [dirname<sup>p529</sup>](#), [formaction<sup>p531</sup>](#), [formenctype<sup>p532</sup>](#), [formmethod<sup>p531</sup>](#), [formnovalidate<sup>p532</sup>](#), [formtarget<sup>p532</sup>](#), [height<sup>p397</sup>](#), [inputmode<sup>p534</sup>](#), [list<sup>p489</sup>](#), [max<sup>p487</sup>](#), [maxlength<sup>p483</sup>](#), [min<sup>p487</sup>](#),  [minlength<sup>p483</sup>](#), [multiple<sup>p485</sup>](#), [pattern<sup>p486</sup>](#), [placeholder<sup>p490</sup>](#), [readonly<sup>p483</sup>](#), [required<sup>p484</sup>](#), [size<sup>p483</sup>](#), [src<sup>p479</sup>](#), [step<sup>p488</sup>](#), and [width<sup>p397</sup>](#) content attributes, the [checked<sup>p492</sup>](#), [files<sup>p493</sup>](#), [valueAsDate<sup>p493</sup>](#), [valueAsNumber<sup>p493</sup>](#), [valueLow<sup>p493</sup>](#), [valueHigh<sup>p493</sup>](#), and [list<sup>p494</sup>](#) IDL attributes, the [select\(\)<sup>p551</sup>](#) method, the [selectionStart<sup>p551</sup>](#), [selectionEnd<sup>p551</sup>](#), and [selectionDirection<sup>p551</sup>](#) IDL attributes, the [setRangeText\(\)<sup>p551</sup>](#) and [setSelectionRange\(\)<sup>p551</sup>](#) methods, the [stepUp\(\)<sup>p494</sup>](#) and [stepDown\(\)<sup>p494</sup>](#) methods, and the [input<sup>p494</sup>](#) and [change<sup>p494</sup>](#) events **apply to** an [input<sup>p452</sup>](#) element depends on the state of its [type<sup>p454</sup>](#) attribute. The subsections that define each type also clearly define in normative "bookkeeping" sections which of these feature apply, and which **do not apply**, to each type. The behaviour of these features depends on whether they apply or not, as defined in their various sections (q.v. for [content attributes<sup>p482</sup>](#), for [APIs<sup>p491</sup>](#), for [events<sup>p494</sup>](#)).

The following table is non-normative and summarizes which of those content attributes, IDL attributes, methods, and events [apply<sup>p455</sup>](#) to each state:

	Hidden <sup>p458</sup>	Text <sup>p458</sup> , Search <sup>p458</sup>	URL <sup>p460</sup> , Telephone <sup>p459</sup>	E-mail <sup>p461</sup>	Password <sup>p462</sup>	Date and Time <sup>p463</sup> , Date <sup>p464</sup> , Month <sup>p465</sup> , Week <sup>p466</sup> , Time <sup>p467</sup>	Local Date and Time <sup>p468</sup>	Number <sup>p469</sup>	Range <sup>p470</sup>	Colour <sup>p474</sup>	Checkbox <sup>p475</sup> , Radio Button <sup>p475</sup>	File Upload <sup>p476</sup>	Buttons <sup>p482</sup>
accept <sup>p477</sup>	.	.	.	.	.	.	.	.	.	.	.	.	Yes

#### Events

<a href="#">input</a> <sup>p494</sup> event	.	Yes	Yes									
<a href="#">change</a> <sup>p494</sup> event	.	Yes	Spec bugs: 24796	Yes								

\* If the [multiple](#)<sup>p485</sup> attribute is not specified.

\*\* If the [multiple](#)<sup>p485</sup> attribute is specified.

Some states of the [type](#)<sup>p454</sup> attribute define a value sanitization algorithm.

Each [input](#)<sup>p452</sup> element has a [value](#)<sup>p527</sup>, which is exposed by the [value](#)<sup>p492</sup> IDL attribute. Some states define an **algorithm to convert a string to a number**, an **algorithm to convert a number to a string**, an **algorithm to convert a string to a Date object**, and an **algorithm to convert a Date object to a string**, which are used by [max](#)<sup>p487</sup>, [min](#)<sup>p487</sup>, [step](#)<sup>p488</sup>, [valueAsDate](#)<sup>p493</sup>, [valueAsNumber](#)<sup>p493</sup>, [valueLow](#)<sup>p493</sup>, [valueHigh](#)<sup>p493</sup>, [stepDown\(\)](#)<sup>p494</sup>, and [stepUp\(\)](#)<sup>p494</sup>.

Each [input](#)<sup>p452</sup> element has a boolean **dirty value flag**. The [dirty value flag](#)<sup>p456</sup> must be initially set to false when the element is created, and must be set to true whenever the user interacts with the control in a way that changes the [value](#)<sup>p527</sup>. (It is also set to true when the value is programmatically changed, as described in the definition of the [value](#)<sup>p492</sup> IDL attribute.)

The **value** content attribute gives the default **value**<sup>p527</sup> of the **input**<sup>p452</sup> element. When the **value**<sup>p457</sup> content attribute is added, set, or removed, if the control's **dirty value flag**<sup>p456</sup> is false, the user agent must set the **value**<sup>p527</sup> of the element to the value of the **value**<sup>p457</sup> content attribute, if there is one, or the empty string otherwise, and then run the current **value sanitization algorithm**<sup>p456</sup>, if one is defined.

Each **input**<sup>p452</sup> element has a **checkedness**<sup>p527</sup>, which is exposed by the **checked**<sup>p492</sup> IDL attribute.

Each **input**<sup>p452</sup> element has a boolean **dirty checkedness flag**. When it is true, the element is said to have a **dirty checkedness**. The **dirty checkedness flag**<sup>p457</sup> must be initially set to false when the element is created, and must be set to true whenever the user interacts with the control in a way that changes the **checkedness**<sup>p527</sup>.

The **checked** content attribute is a **boolean attribute**<sup>p59</sup> that gives the default **checkedness**<sup>p527</sup> of the **input**<sup>p452</sup> element. When the **checked**<sup>p457</sup> content attribute is added, if the control does not have **dirty checkedness**<sup>p457</sup>, the user agent must set the **checkedness**<sup>p527</sup> of the element to true; when the **checked**<sup>p457</sup> content attribute is removed, if the control does not have **dirty checkedness**<sup>p457</sup>, the user agent must set the **checkedness**<sup>p527</sup> of the element to false.

The **reset algorithm**<sup>p567</sup> for **input**<sup>p452</sup> elements is to set the **dirty value flag**<sup>p456</sup> and **dirty checkedness flag**<sup>p457</sup> back to false, set the **value**<sup>p527</sup> of the element to the value of the **value**<sup>p457</sup> content attribute, if there is one, or the empty string otherwise, set the **checkedness**<sup>p527</sup> of the element to true if the element has a **checked**<sup>p457</sup> content attribute and false if it does not, empty the list of **selected files**<sup>p476</sup>, and then invoke the **value sanitization algorithm**<sup>p456</sup>, if the **type**<sup>p454</sup> attribute's current state defines one.

Each **input**<sup>p452</sup> element can be **mutable**<sup>p527</sup>. Except where otherwise specified, an **input**<sup>p452</sup> element is always **mutable**<sup>p527</sup>. Similarly, except where otherwise specified, the user agent should not allow the user to modify the element's **value**<sup>p527</sup> or **checkedness**<sup>p527</sup>.

When an **input**<sup>p452</sup> element is **disabled**<sup>p530</sup>, it is not **mutable**<sup>p527</sup>.

**Note** *The **readonly**<sup>p483</sup> attribute can also in some cases (e.g. for the **Date**<sup>p464</sup> state, but not the **Checkbox**<sup>p475</sup> state) stop an **input**<sup>p452</sup> element from being **mutable**<sup>p527</sup>.*

The **cloning steps**<sup>p51</sup> for **input**<sup>p452</sup> elements must propagate the **value**<sup>p527</sup>, **dirty value flag**<sup>p456</sup>, **checkedness**<sup>p527</sup>, and **dirty checkedness flag**<sup>p457</sup> from the node being cloned to the copy.

When an **input**<sup>p452</sup> element is first created, the element's rendering and behaviour must be set to the rendering and behaviour defined for the **type**<sup>p454</sup> attribute's state, and the **value sanitization algorithm**<sup>p456</sup>, if one is defined for the **type**<sup>p454</sup> attribute's state, must be invoked. Spec bugs: 27791

When an **input**<sup>p452</sup> element's **type**<sup>p454</sup> attribute changes state, the user agent must run the following steps:

1. If the previous state of the element's **type**<sup>p454</sup> attribute put the **value**<sup>p492</sup> IDL attribute in the **value**<sup>p492</sup> mode, and the element's **value**<sup>p527</sup> is not the empty string, and the new state of the element's **type**<sup>p454</sup> attribute puts the **value**<sup>p492</sup> IDL attribute in either the **default**<sup>p492</sup> mode or the **default/on**<sup>p492</sup> mode, then set the element's **value**<sup>p457</sup> content attribute to the element's **value**<sup>p527</sup>.
2. Otherwise, if the previous state of the element's **type**<sup>p454</sup> attribute put the **value**<sup>p492</sup> IDL attribute in any mode other than the **value**<sup>p492</sup> mode, and the new state of the element's **type**<sup>p454</sup> attribute puts the **value**<sup>p492</sup> IDL attribute in the **value**<sup>p492</sup> mode, then set the **value**<sup>p527</sup> of the element to the value of the **value**<sup>p457</sup> content attribute, if there is one, or the empty string otherwise, and then set the control's **dirty value flag**<sup>p456</sup> to false.
3. Update the element's rendering and behaviour to the new state's.
4. **Signal a type change** for the element. (The **Radio Button**<sup>p475</sup> state uses this, in particular.)
5. Invoke the **value sanitization algorithm**<sup>p456</sup>, if one is defined for the **type**<sup>p454</sup> attribute's new state.

The **name**<sup>p529</sup> attribute represents the element's name. The **dirname**<sup>p529</sup> attribute controls how the element's **directionality**<sup>p125</sup> is submitted. The **disabled**<sup>p530</sup> attribute is used to make the control non-interactive and to prevent its value from being submitted. The **form**<sup>p527</sup> attribute is used to explicitly associate the **input**<sup>p452</sup> element with its **form owner**<sup>p527</sup>. The **autofocus**<sup>p533</sup> attribute controls focus. The **inputmode**<sup>p534</sup> attribute controls the user interface's input modality for the control. The **autocomplete**<sup>p535</sup> attribute controls how the user agent provides autofill behaviour.

The **indeterminate** IDL attribute must initially be set to false. On getting, it must return the last value it was set to. On setting, it must be set to the new value. It has no effect except for changing the appearance of **checkbox**<sup>p475</sup> controls.

The `accept`, `alt`, `max`, `min`, `multiple`, `pattern`, `placeholder`, `required`, `size`, `src`, and `step` IDL attributes must `reflect`<sup>p88</sup> the respective content attributes of the same name. The `dirName` IDL attribute must `reflect`<sup>p88</sup> the `dirname`<sup>b529</sup> content attribute. The `readOnly` IDL attribute must `reflect`<sup>p88</sup> the `readonly`<sup>p483</sup> content attribute. The `defaultChecked` IDL attribute must `reflect`<sup>p88</sup> the `checked`<sup>p457</sup> content attribute. The `defaultValue` IDL attribute must `reflect`<sup>p88</sup> the `value`<sup>p457</sup> content attribute.

The `type` IDL attribute must `reflect`<sup>p88</sup> the respective content attribute of the same name, `limited to only known values`<sup>p89</sup>. The `inputMode` IDL attribute must `reflect`<sup>p88</sup> the `inputmode`<sup>p534</sup> content attribute, `limited to only known values`<sup>p89</sup>. The `maxLength` IDL attribute must `reflect`<sup>p88</sup> the `maxlength`<sup>p483</sup> content attribute, `limited to only non-negative numbers`<sup>p89</sup>. The `minLength` IDL attribute must `reflect`<sup>p88</sup> the `minlength`<sup>p483</sup> content attribute, `limited to only non-negative numbers`<sup>p89</sup>.

The IDL attributes `width` and `height` must return the rendered width and height of the image, in CSS pixels, if an image is `being rendered`<sup>p1058</sup>, and is being rendered to a visual medium; or else the intrinsic width and height of the image, in CSS pixels, if an image is `available`<sup>p480</sup> but not being rendered to a visual medium; or else 0, if no image is `available`<sup>p480</sup>. When the `input`<sup>p452</sup> element's `type`<sup>p454</sup> attribute is not in the `Image Button`<sup>p479</sup> state, then no image is `available`<sup>p480</sup>. [CSS]<sup>p1149</sup>

On setting, they must act as if they `reflected`<sup>p88</sup> the respective content attributes of the same name.

The `willValidate`<sup>p555</sup>, `validity`<sup>p556</sup>, and `validationMessage`<sup>p557</sup> IDL attributes, and the `checkValidity()`<sup>p556</sup>, `reportValidity()`<sup>p557</sup>, and `setCustomValidity()`<sup>p555</sup> methods, are part of the `constraint validation API`<sup>p554</sup>. The `labels`<sup>p452</sup> IDL attribute provides a list of the element's `label`<sup>p451</sup>s. The `select()`<sup>p551</sup>, `selectionStart`<sup>p551</sup>, `selectionEnd`<sup>p551</sup>, `selectionDirection`<sup>p551</sup>, `setRangeText()`<sup>p551</sup>, and `setSelectionRange()`<sup>p551</sup> methods and IDL attributes expose the element's text selection. The `autofocus`<sup>p533</sup>, `disabled`<sup>p530</sup>, `form`<sup>p529</sup>, and `name`<sup>p529</sup> IDL attributes are part of the element's forms API.

#### 4.10.5.1 States of the `type`<sup>p454</sup> attribute

##### 4.10.5.1.1 Hidden state (`type=hidden`)

When an `input`<sup>p452</sup> element's `type`<sup>p454</sup> attribute is in the `Hidden`<sup>p458</sup> state, the rules in this section apply.

The `input`<sup>p452</sup> element `represents`<sup>p111</sup> a value that is not intended to be examined or manipulated by the user.

**Constraint validation:** If an `input`<sup>p452</sup> element's `type`<sup>p454</sup> attribute is in the `Hidden`<sup>p458</sup> state, it is `barred from constraint validation`<sup>p553</sup>.

If the `name`<sup>b529</sup> attribute is present and has a value that is a `case-sensitive`<sup>p58</sup> match for the string "`charset`<sup>p529</sup>", then the element's `value`<sup>p457</sup> attribute must be omitted.

##### Bookkeeping details

- The `autocomplete`<sup>b535</sup> content attribute `applies`<sup>p455</sup> to this element.
- The `value`<sup>p492</sup> IDL attribute `applies`<sup>p455</sup> to this element and is in mode `default`<sup>p492</sup>.
- The following content attributes must not be specified and `do not apply`<sup>p456</sup> to the element: `accept`<sup>p477</sup>, `alt`<sup>p480</sup>, `checked`<sup>p457</sup>, `dirname`<sup>b529</sup>, `formaction`<sup>p531</sup>, `formenctype`<sup>p532</sup>, `formmethod`<sup>p531</sup>, `formnovalidate`<sup>p532</sup>, `formtarget`<sup>p532</sup>, `height`<sup>p397</sup>, `inputmode`<sup>p534</sup>, `list`<sup>p489</sup>, `max`<sup>p487</sup>, `maxlength`<sup>p483</sup>, `min`<sup>p487</sup>, `minlength`<sup>p483</sup>, `multiple`<sup>p485</sup>, `pattern`<sup>p486</sup>, `placeholder`<sup>p490</sup>, `readonly`<sup>p483</sup>, `required`<sup>p484</sup>, `size`<sup>p483</sup>, `src`<sup>p479</sup>, `step`<sup>b488</sup>, and `width`<sup>p397</sup>.
- The following IDL attributes and methods `do not apply`<sup>p456</sup> to the element: `checked`<sup>p492</sup>, `files`<sup>p493</sup>, `list`<sup>p494</sup>, `selectionStart`<sup>p551</sup>, `selectionEnd`<sup>p551</sup>, `selectionDirection`<sup>p551</sup>, `valueAsDate`<sup>p493</sup>, `valueAsNumber`<sup>p493</sup>, `valueLow`<sup>p493</sup>, and `valueHigh`<sup>p493</sup> IDL attributes; `select()`<sup>p551</sup>, `setRangeText()`<sup>p551</sup>, `setSelectionRange()`<sup>p551</sup>, `stepDown()`<sup>p494</sup>, and `stepUp()`<sup>p494</sup> methods.
- The `input`<sup>p494</sup> and `change`<sup>p494</sup> events `do not apply`<sup>p455</sup>.

##### 4.10.5.1.2 Text (`type=text`) state and Search state (`type=search`)

When an `input`<sup>p452</sup> element's `type`<sup>p454</sup> attribute is in the `Text`<sup>p458</sup> state or the `Search`<sup>p458</sup> state, the rules in this section apply.

The `input`<sup>p452</sup> element `represents`<sup>p111</sup> a one line plain text edit control for the element's `value`<sup>p527</sup>.

**Note** The difference between the `Text`<sup>p458</sup> state and the `Search`<sup>p458</sup> state is primarily stylistic: on platforms where search fields are distinguished from regular text fields, the `Search`<sup>p458</sup> state might result in an appearance consistent with the platform's search fields rather than appearing like a regular text field.

If the element is [mutable](#), its [value](#) should be editable by the user. User agents must not allow users to insert U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters into the element's [value](#).

If the element is [mutable](#), the user agent should allow the user to change the writing direction of the element, setting it either to a left-to-right writing direction or a right-to-left writing direction. If the user does so, the user agent must then run the following steps:

1. Set the element's [dir](#) attribute to "[ltr](#)" if the user selected a left-to-right writing direction, and "[rtl](#)" if the user selected a right-to-left writing direction.
2. [Queue a task](#) to [fire a simple event](#) that bubbles named [input](#) at the [input](#) element.

The [value](#) attribute, if specified, must have a value that contains no U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters.

The [value sanitization algorithm](#) is as follows: [Strip line breaks](#) from the [value](#).

#### Bookkeeping details

- The following common [input](#) element content attributes, IDL attributes, and methods [apply](#) to the element: [autocomplete](#), [dirname](#), [inputmode](#), [list](#), [maxlength](#), [minlength](#), [pattern](#), [placeholder](#), [readonly](#), [required](#), and [size](#) content attributes; [list](#), [selectionStart](#), [selectionEnd](#), [selectionDirection](#), and [value](#) IDL attributes; [select\(\)](#), [setRangeText\(\)](#), and [setSelectionRange\(\)](#) methods.
- The [value](#) IDL attribute is in mode [value](#).
- The [input](#) and [change](#) events [apply](#).
- The following content attributes must not be specified and [do not apply](#) to the element: [accept](#), [alt](#), [checked](#), [formaction](#), [formenctype](#), [formmethod](#), [formnovalidate](#), [formtarget](#), [height](#), [max](#), [min](#), [multiple](#), [src](#), [step](#), and [width](#).
- The following IDL attributes and methods [do not apply](#) to the element: [checked](#), [files](#), [valueAsDate](#), [valueAsNumber](#), [valueLow](#), and [valueHigh](#) IDL attributes; [stepDown\(\)](#) and [stepUp\(\)](#) methods.

#### 4.10.5.1.3 Telephone state (`type=tel`)

When an [input](#) element's [type](#) attribute is in the [Telephone](#) state, the rules in this section apply.

The [input](#) element [represents](#) a control for editing a telephone number given in the element's [value](#).

If the element is [mutable](#), its [value](#) should be editable by the user. User agents may change the spacing and, with care, the punctuation of [values](#) that the user enters. User agents must not allow users to insert U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters into the element's [value](#).

The [value](#) attribute, if specified, must have a value that contains no U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters.

The [value sanitization algorithm](#) is as follows: [Strip line breaks](#) from the [value](#).

**Note** Unlike the [URL](#) and [E-mail](#) types, the [Telephone](#) type does not enforce a particular syntax. This is intentional; in practice, telephone number fields tend to be free-form fields, because there are a wide variety of valid phone numbers. Systems that need to enforce a particular format are encouraged to use the [pattern](#) attribute or the [setCustomValidity\(\)](#) method to hook into the client-side validation mechanism.

#### Bookkeeping details

- The following common [input](#) element content attributes, IDL attributes, and methods [apply](#) to the element: [autocomplete](#), [list](#), [maxlength](#), [minlength](#), [pattern](#), [placeholder](#), [readonly](#), [required](#), and [size](#) content attributes; [list](#), [selectionStart](#), [selectionEnd](#), [selectionDirection](#), and [value](#) IDL attributes; [select\(\)](#), [setRangeText\(\)](#), and [setSelectionRange\(\)](#) methods.
- The [value](#) IDL attribute is in mode [value](#).
- The [input](#) and [change](#) events [apply](#).
- The following content attributes must not be specified and [do not apply](#) to the element: [accept](#), [alt](#), [checked](#), [dirname](#), [formaction](#), [formenctype](#), [formmethod](#), [formnovalidate](#), [formtarget](#), [height](#), [inputmode](#), [max](#), [min](#), [multiple](#), [src](#), [step](#), and [width](#).
- The following IDL attributes and methods [do not apply](#) to the element: [checked](#), [files](#), [valueAsDate](#), [valueAsNumber](#), [valueLow](#), and [valueHigh](#) IDL attributes; [stepDown\(\)](#) and [stepUp\(\)](#) methods.

#### 4.10.5.1.4 URL state (`type=url`)

When an `input`<sup>p452</sup> element's `type`<sup>p454</sup> attribute is in the `URL`<sup>p460</sup> state, the rules in this section apply.

The `input`<sup>p452</sup> element `represents`<sup>p111</sup> a control for editing a single `absolute URL`<sup>p48</sup> given in the element's `value`<sup>p527</sup>.

If the element is `mutable`<sup>p527</sup>, the user agent should allow the user to change the URL represented by its `value`<sup>p527</sup>. User agents may allow the user to set the `value`<sup>p527</sup> to a string that is not a `valid`<sup>p81</sup> `absolute URL`<sup>p48</sup>, but may also or instead automatically escape characters entered by the user so that the `value`<sup>p527</sup> is always a `valid`<sup>p81</sup> `absolute URL`<sup>p48</sup> (even if that isn't the actual value seen and edited by the user in the interface). User agents should allow the user to set the `value`<sup>p527</sup> to the empty string. User agents must not allow users to insert U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters into the `value`<sup>p527</sup>.

The `value`<sup>p457</sup> attribute, if specified and not empty, must have a value that is a `valid URL potentially surrounded by spaces`<sup>p82</sup> that is also an `absolute URL`<sup>p48</sup>.

The `value sanitization algorithm`<sup>p456</sup> is as follows: `Strip line breaks`<sup>p59</sup> from the `value`<sup>p527</sup>, then `strip leading and trailing whitespace`<sup>p59</sup> from the `value`<sup>p527</sup>.

**Constraint validation:** While the `value`<sup>p527</sup> of the element is neither the empty string nor a `valid`<sup>p81</sup> `absolute URL`<sup>p48</sup>, the element is `suffering from a type mismatch`<sup>p553</sup>.

##### Bookkeeping details

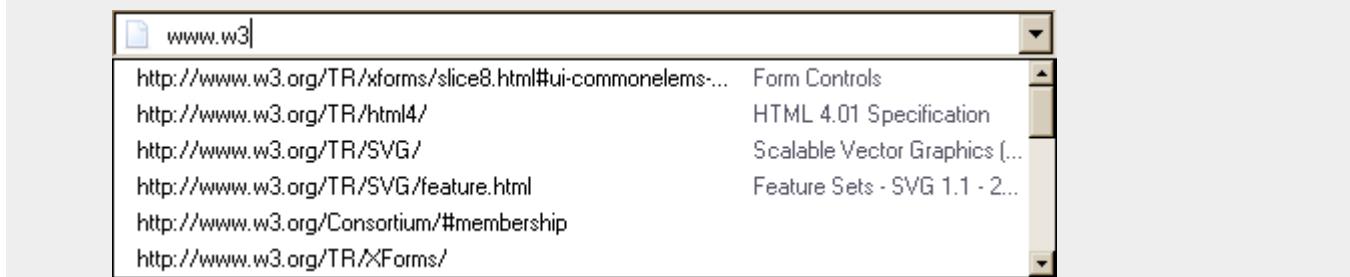

- The following common `input`<sup>p452</sup> element content attributes, IDL attributes, and methods `apply`<sup>p455</sup> to the element: `autocomplete`<sup>p535</sup>, `list`<sup>p489</sup>, `maxlength`<sup>p483</sup>, `minlength`<sup>p483</sup>, `pattern`<sup>p486</sup>, `placeholder`<sup>p490</sup>, `readonly`<sup>p483</sup>, `required`<sup>p484</sup>, and `size`<sup>p483</sup> content attributes; `list`<sup>p494</sup>, `selectionStart`<sup>p551</sup>, `selectionEnd`<sup>p551</sup>, `selectionDirection`<sup>p551</sup>, and `value`<sup>p492</sup> IDL attributes; `select()`<sup>p551</sup>, `setRangeText()`<sup>p551</sup>, and `setSelectionRange()`<sup>p551</sup> methods.
- The `value`<sup>p492</sup> IDL attribute is in mode `value`<sup>p492</sup>.
- The `input`<sup>p494</sup> and `change`<sup>p494</sup> events `apply`<sup>p455</sup>.
- The following content attributes must not be specified and `do not apply`<sup>p455</sup> to the element: `accept`<sup>p477</sup>, `alt`<sup>p480</sup>, `checked`<sup>p457</sup>, `dirname`<sup>p529</sup>, `formaction`<sup>p531</sup>, `formenctype`<sup>p532</sup>, `formmethod`<sup>p531</sup>, `formnovalidate`<sup>p532</sup>, `formtarget`<sup>p532</sup>, `height`<sup>p397</sup>, `inputmode`<sup>p534</sup>, `max`<sup>p487</sup>, `min`<sup>p487</sup>, `multiple`<sup>p485</sup>, `src`<sup>p479</sup>, `step`<sup>p488</sup>, and `width`<sup>p397</sup>.
- The following IDL attributes and methods `do not apply`<sup>p455</sup> to the element: `checked`<sup>p492</sup>, `files`<sup>p493</sup>, `valueAsDate`<sup>p493</sup>, `valueAsNumber`<sup>p493</sup>, `valueLow`<sup>p493</sup>, and `valueHigh`<sup>p493</sup> IDL attributes; `stepDown()`<sup>p494</sup> and `stepUp()`<sup>p494</sup> methods.

##### Example

If a document contained the following markup:

```
<input type="url" name="location" list="urls">
<datalist id="urls">
 <option label="MIME: Format of Internet Message Bodies" value="http://tools.ietf.org/html/rfc2045">
 <option label="HTML 4.01 Specification" value="http://www.w3.org/TR/html4/">
 <option label="Form Controls" value="http://www.w3.org/TR/xforms/slice8.html#ui-commonelems-hint">
 <option label="Scalable Vector Graphics (SVG) 1.1 Specification" value="http://www.w3.org/TR/SVG/>
 <option label="Feature Sets - SVG 1.1 - 20030114" value="http://www.w3.org/TR/SVG/feature.html">
 <option label="The Single UNIX Specification, Version 3" value="http://www.unix-systems.org/version3/">
</datalist>
```

...and the user had typed "www.w3", and the user agent had also found that the user had visited <http://www.w3.org/> Consortium/#membership and <http://www.w3.org/TR/XForms/> in the recent past, then the rendering might look like this:

The first four URLs in this sample consist of the four URLs in the author-specified list that match the text the user has entered, sorted in some UA-defined manner (maybe by how frequently the user refers to those URLs). Note how the UA is using the knowledge that the values are URLs to allow the user to omit the scheme part and perform intelligent matching on the domain name.

The last two URLs (and probably many more, given the scrollbar's indications of more values being available) are the matches from the user agent's session history data. This data is not made available to the page DOM. In this particular case, the UA has no titles to provide for those values.

#### 4.10.5.1.5 E-mail state (`type=email`)

Spec bugs: [15489](#), [18162](#)

When an `input`<sup>p452</sup> element's `type`<sup>p454</sup> attribute is in the `E-mail`<sup>p461</sup> state, the rules in this section apply.

How the `E-mail`<sup>p461</sup> state operates depends on whether the `multiple`<sup>p485</sup> attribute is specified or not.

##### ↪ When the `multiple`<sup>p485</sup> attribute is not specified on the element

The `input`<sup>p452</sup> element `represents`<sup>p111</sup> a control for editing an e-mail address given in the element's `value`<sup>p527</sup>.

If the element is `mutable`<sup>p527</sup>, the user agent should allow the user to change the e-mail address represented by its `value`<sup>p527</sup>. User agents may allow the user to set the `value`<sup>p527</sup> to a string that is not a `valid e-mail address`<sup>p462</sup>. The user agent should act in a manner consistent with expecting the user to provide a single e-mail address. User agents should allow the user to set the `value`<sup>p527</sup> to the empty string.

User agents must not allow users to insert U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters into the `value`<sup>p527</sup>.

User agents may transform the `value`<sup>p527</sup> for display and editing; in particular, user agents should convert punycode in the domain labels of the `value`<sup>p527</sup> to IDN in the display and vice versa.

**Constraint validation:** While the user interface is representing input that the user agent cannot convert to punycode, the control is `suffering from bad input`<sup>p553</sup>.

The `value`<sup>p457</sup> attribute, if specified and not empty, must have a value that is a single `valid e-mail address`<sup>p462</sup>.

**The `value sanitization algorithm`<sup>p456</sup> is as follows:** `Strip line breaks`<sup>p59</sup> from the `value`<sup>p527</sup>, then `strip leading and trailing whitespace`<sup>p59</sup> from the `value`<sup>p527</sup>.

**Constraint validation:** While the `value`<sup>p527</sup> of the element is neither the empty string nor a single `valid e-mail address`<sup>p462</sup>, the element is `suffering from a type mismatch`<sup>p553</sup>.

##### ↪ When the `multiple`<sup>p485</sup> attribute is specified on the element

The `input`<sup>p452</sup> element `represents`<sup>p111</sup> a control for adding, removing, and editing the e-mail addresses given in the element's `values`<sup>p527</sup>.

If the element is `mutable`<sup>p527</sup>, the user agent should allow the user to add, remove, and edit the e-mail addresses represented by its `values`<sup>p527</sup>. User agents may allow the user to set any individual value in the list of `values`<sup>p527</sup> to a string that is not a `valid e-mail address`<sup>p462</sup>, but must not allow users to set any individual value to a string containing U+002C COMMA (,), U+000A LINE FEED (LF), or U+000D CARRIAGE RETURN (CR) characters. User agents should allow the user to remove all the addresses in the element's `values`<sup>p527</sup>. User agents may transform the `values`<sup>p527</sup> for display and editing; in particular, user agents should convert punycode in the domain labels of the `value`<sup>p527</sup> to IDN in the display and vice versa.

**Constraint validation:** While the user interface describes a situation where an individual value contains a U+002C COMMA (,) or is representing input that the user agent cannot convert to punycode, the control is `suffering from bad input`<sup>p553</sup>.

Whenever the user changes the element's `values`<sup>p527</sup>, the user agent must run the following steps:

1. Let `latest values` be a copy of the element's `values`<sup>p527</sup>.
2. `Strip leading and trailing whitespace`<sup>p59</sup> from each value in `latest values`.
3. Let the element's `value`<sup>p527</sup> be the result of concatenating all the values in `latest values`, separating each value from the next by a single U+002C COMMA character (,), maintaining the list's order.

The `value`<sup>p457</sup> attribute, if specified, must have a value that is a `valid e-mail address list`<sup>p462</sup>.

**The `value sanitization algorithm`<sup>p456</sup> is as follows:**

1. Split on commas<sup>p81</sup> the element's value<sup>p527</sup>, strip leading and trailing whitespace<sup>p59</sup> from each resulting token, if any, and let the element's values<sup>p527</sup> be the (possibly empty) resulting list of (possibly empty) tokens, maintaining the original order.
2. Let the element's value<sup>p527</sup> be the result of concatenating the element's values<sup>p527</sup>, separating each value from the next by a single U+002C COMMA character (,), maintaining the list's order.

**Constraint validation:** While the value<sup>p527</sup> of the element is not a valid e-mail address list<sup>p462</sup>, the element is suffering from a type mismatch<sup>p553</sup>.

When the multiple<sup>p485</sup> attribute is set or removed, the user agent must run the value sanitization algorithm<sup>p456</sup>.

A **valid e-mail address** is a string that matches the email production of the following ABNF, the character set for which is Unicode. This ABNF implements the extensions described in RFC 1123. [ABNF]<sup>p1148</sup> [RFC5322]<sup>p1153</sup> [RFC1034]<sup>p1152</sup> [RFC1123]<sup>p1152</sup>

```

email = 1*(atext / ".") "@" label *("." label)
label = let-dig [[ldh-str] let-dig] ; limited to a length of 63 characters by RFC 1034 section 3.5
atext = < as defined in RFC 5322 section 3.2.3 >
let-dig = < as defined in RFC 1034 section 3.5 >
ldh-str = < as defined in RFC 1034 section 3.5 >

```

**Note** This requirement is a willful violation<sup>p26</sup> of RFC 5322, which defines a syntax for e-mail addresses that is simultaneously too strict (before the "@" character), too vague (after the "@" character), and too lax (allowing comments, whitespace characters, and quoted strings in manners unfamiliar to most users) to be of practical use here.

**Note** The following JavaScript- and Perl-compatible regular expression is an implementation of the above definition.

```
/^@[a-zA-Z0-9_.!#$%&'*+=?^`{|}~-]+@[a-zA-Z0-9] (?:[a-zA-Z0-9-]{0,61}[a-zA-Z0-9])?(?:\.[a-zA-Z0-9]?:[a-zA-Z0-9-]{0,61}[a-zA-Z0-9])*
```

A **valid e-mail address list** is a set of comma-separated tokens<sup>p80</sup>, where each token is itself a valid e-mail address<sup>p462</sup>. To obtain the list of tokens from a valid e-mail address list<sup>p462</sup>, and implementation must split the string on commas<sup>p81</sup>.

#### Bookkeeping details

- The following common input<sup>p452</sup> element content attributes, IDL attributes, and methods apply<sup>p456</sup> to the element: autocomplete<sup>p535</sup>, list<sup>p489</sup>, maxlength<sup>p483</sup>, minlength<sup>p483</sup>, multiple<sup>p485</sup>, pattern<sup>p486</sup>, placeholder<sup>p490</sup>, readonly<sup>p483</sup>, required<sup>p484</sup>, and size<sup>p483</sup> content attributes; list<sup>p494</sup> and value<sup>p492</sup> IDL attributes; select()<sup>p551</sup> method.
- The value<sup>p492</sup> IDL attribute is in mode value<sup>p492</sup>.
- The input<sup>p494</sup> and change<sup>p494</sup> events apply<sup>p456</sup>.
- The following content attributes must not be specified and do not apply<sup>p456</sup> to the element: accept<sup>p477</sup>, alt<sup>p480</sup>, checked<sup>p457</sup>, dirname<sup>p529</sup>, formaction<sup>p531</sup>, formenctype<sup>p532</sup>, formmethod<sup>p531</sup>, formnovalidate<sup>p532</sup>, formtarget<sup>p532</sup>, height<sup>p397</sup>, inputmode<sup>p534</sup>, max<sup>p487</sup>, min<sup>p487</sup>, src<sup>p479</sup>, step<sup>p488</sup>, and width<sup>p397</sup>.
- The following IDL attributes and methods do not apply<sup>p456</sup> to the element: checked<sup>p492</sup>, files<sup>p493</sup>, selectionStart<sup>p551</sup>, selectionEnd<sup>p551</sup>, selectionDirection<sup>p551</sup>, valueAsDate<sup>p493</sup>, valueAsNumber<sup>b493</sup>, valueLow<sup>p493</sup>, and valueHigh<sup>b493</sup> IDL attributes; setRangeText()<sup>p551</sup>, setSelectionRange()<sup>p551</sup>, stepDown()<sup>p494</sup> and stepUp()<sup>p494</sup> methods.

#### 4.10.5.1.6 Password state (type=password)

When an input<sup>p452</sup> element's type<sup>p454</sup> attribute is in the Password<sup>p462</sup> state, the rules in this section apply.

The input<sup>p452</sup> element represents<sup>p111</sup> a one line plain text edit control for the element's value<sup>p527</sup>. The user agent should obscure the value so that people other than the user cannot see it.

If the element is mutable<sup>b527</sup>, its value<sup>p527</sup> should be editable by the user. User agents must not allow users to insert U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters into the value<sup>p527</sup>.

The value<sup>p457</sup> attribute, if specified, must have a value that contains no U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters.

The value sanitization algorithm<sup>p456</sup> is as follows: Strip line breaks<sup>p59</sup> from the value<sup>p527</sup>.

#### Bookkeeping details

- The following common `input`<sup>p452</sup> element content attributes, IDL attributes, and methods `apply`<sup>p455</sup> to the element: `autocomplete`<sup>p535</sup>, `inputmode`<sup>p534</sup>, `maxlength`<sup>p483</sup>, `minlength`<sup>p483</sup>, `pattern`<sup>p486</sup>, `placeholder`<sup>p490</sup>, `readonly`<sup>p483</sup>, `required`<sup>p484</sup>, and `size`<sup>p483</sup> content attributes; `selectionStart`<sup>p551</sup>, `selectionEnd`<sup>p551</sup>, `selectionDirection`<sup>p551</sup>, and `value`<sup>p492</sup> IDL attributes; `select()`<sup>p551</sup>, `setRangeText()`<sup>p551</sup>, and `setSelectionRange()`<sup>p551</sup> methods.
- The `value`<sup>p492</sup> IDL attribute is in mode `value`<sup>p492</sup>.
- The `input`<sup>p494</sup> and `change`<sup>p494</sup> events `apply`<sup>p455</sup>.
- The following content attributes must not be specified and `do not apply`<sup>p455</sup> to the element: `accept`<sup>p477</sup>, `alt`<sup>p480</sup>, `checked`<sup>p527</sup>, `dirname`<sup>p529</sup>, `formaction`<sup>p531</sup>, `formenctype`<sup>p532</sup>, `formmethod`<sup>p531</sup>, `formnovalidate`<sup>p532</sup>, `formtarget`<sup>p532</sup>, `height`<sup>p397</sup>, `list`<sup>p489</sup>, `max`<sup>p487</sup>, `min`<sup>p487</sup>, `multiple`<sup>p485</sup>, `src`<sup>p479</sup>, `step`<sup>p488</sup>, and `width`<sup>p397</sup>.
- The following IDL attributes and methods `do not apply`<sup>p455</sup> to the element: `checked`<sup>p492</sup>, `files`<sup>p493</sup>, `list`<sup>p494</sup>, `valueAsDate`<sup>p493</sup>, `valueAsNumber`<sup>p493</sup>, `valueLow`<sup>p493</sup>, and `valueHigh`<sup>p493</sup> IDL attributes; `stepDown()`<sup>p494</sup> and `stepUp()`<sup>p494</sup> methods.

#### 4.10.5.1.7 Date and Time state (`type=datetime`)

When an `input`<sup>p452</sup> element's `type`<sup>p454</sup> attribute is in the `Date and Time`<sup>p463</sup> state, the rules in this section apply.

The `input`<sup>p452</sup> element `represents`<sup>p111</sup> a control for setting the element's `value`<sup>p527</sup> to a string representing a specific `global date and time`<sup>p72</sup>. User agents may display the date and time in whatever time zone is appropriate for the user.

If the element is `mutable`<sup>p527</sup>, the user agent should allow the user to change the `global date and time`<sup>p72</sup> represented by its `value`<sup>p527</sup>, as obtained by `parsing a global date and time`<sup>p73</sup> from it. User agents must not allow the user to set the `value`<sup>p527</sup> to a non-empty string that is not a `valid normalised forced-UTC global date and time string`<sup>p73</sup>, though user agents may allow the user to set and view the time in another time zone and silently translate the time to and from the UTC time zone in the `value`<sup>p527</sup>. If the user agent provides a user interface for selecting a `global date and time`<sup>p72</sup>, then the `value`<sup>p527</sup> must be set to a `valid normalised forced-UTC global date and time string`<sup>p73</sup> representing the user's selection. User agents should allow the user to set the `value`<sup>p527</sup> to the empty string.

**Constraint validation:** While the user interface describes input that the user agent cannot convert to a `valid normalised forced-UTC global date and time string`<sup>p73</sup>, the control is `suffering from bad input`<sup>p553</sup>.

**Note** See the `introduction section`<sup>p446</sup> for a discussion of the difference between the `input` format and submission format for date, time, and number form controls, and the `implementation notes`<sup>p482</sup> regarding localization of form controls.

The `value`<sup>p457</sup> attribute, if specified and not empty, must have a value that is a `valid global date and time string`<sup>p72</sup>.

**The `value sanitization algorithm`<sup>p456</sup> is as follows:** If the `value`<sup>p527</sup> of the element is a `valid global date and time string`<sup>p72</sup>, then adjust the time so that the `value`<sup>p527</sup> represents the same point in time but expressed in the UTC time zone as a valid normalized forced-UTC global date and time string, otherwise, set it to the empty string instead.

The `min`<sup>p487</sup> attribute, if specified, must have a value that is a `valid global date and time string`<sup>p72</sup>. The `max`<sup>p487</sup> attribute, if specified, must have a value that is a `valid global date and time string`<sup>p72</sup>.

The `step`<sup>p488</sup> attribute is expressed in seconds. The `step scale factor`<sup>p488</sup> is 1000 (which converts the seconds to milliseconds, as used in the other algorithms). The `default step`<sup>p488</sup> is 60 seconds.

When the element is `suffering from a step mismatch`<sup>p553</sup>, the user agent may round the element's `value`<sup>p527</sup> to the nearest `global date and time`<sup>p72</sup> for which the element would not `suffer from a step mismatch`<sup>p553</sup>.

**The `algorithm to convert a string to a number`<sup>p456</sup>, given a string `input`, is as follows:** If `parsing a global date and time`<sup>p73</sup> from `input` results in an error, then return an error; otherwise, return the number of milliseconds elapsed from midnight UTC on the morning of 1970-01-01 (the time represented by the value "1970-01-01T00:00:00.0Z") to the parsed `global date and time`<sup>p72</sup>, ignoring leap seconds.

**The `algorithm to convert a number to a string`<sup>p456</sup>, given a number `input`, is as follows:** Return a `valid normalised forced-UTC global date and time string`<sup>p73</sup> that represents the `global date and time`<sup>p72</sup> that is `input` milliseconds after midnight UTC on the morning of 1970-01-01 (the time represented by the value "1970-01-01T00:00:00.0Z").

**The `algorithm to convert a string to a Date object`<sup>p456</sup>, given a string `input`, is as follows:** If `parsing a global date and time`<sup>p73</sup> from `input` results in an error, then return an error; otherwise, return a new `Date` object<sup>p50</sup> representing the parsed `global date and time`<sup>p72</sup>, expressed in UTC.

**The `algorithm to convert a Date object to a string`<sup>p456</sup>, given a `Date`<sup>p49</sup> object `input`, is as follows:** Return a `valid normalised forced-UTC global date and time string`<sup>p73</sup> that represents the `global date and time`<sup>p72</sup> that is represented by `input`.

**Note**

The [Date and Time](#)<sup>p463</sup> state (and other date- and time-related states described in subsequent sections) is not intended for the entry of values for which a precise date and time relative to the contemporary calendar cannot be established. For example, it would be inappropriate for the entry of times like "one millisecond after the big bang", "the early part of the Jurassic period", or "a winter around 250 BCE".

For the input of dates before the introduction of the Gregorian calendar, authors are encouraged to not use the [Date and Time](#)<sup>p463</sup> state (and the other date- and time-related states described in subsequent sections), as user agents are not required to support converting dates and times from earlier periods to the Gregorian calendar, and asking users to do so manually puts an undue burden on users. (This is complicated by the manner in which the Gregorian calendar was phased in, which occurred at different times in different countries, ranging from partway through the 16th century all the way to early in the 20th.) Instead, authors are encouraged to provide fine-grained input controls using the [select](#)<sup>p498</sup> element and [input](#)<sup>p452</sup> elements with the [Number](#)<sup>p469</sup> state.

#### Bookkeeping details

- The following common [input](#)<sup>p452</sup> element content attributes, IDL attributes, and methods [apply](#)<sup>p455</sup> to the element: [autocomplete](#)<sup>p535</sup>, [list](#)<sup>p489</sup>, [max](#)<sup>p487</sup>, [min](#)<sup>p487</sup>, [readonly](#)<sup>p483</sup>, [required](#)<sup>p484</sup>, and [step](#)<sup>p488</sup> content attributes; [list](#)<sup>p494</sup>, [value](#)<sup>p492</sup>, [valueAsDate](#)<sup>p493</sup>, and [valueAsNumber](#)<sup>p493</sup> IDL attributes; [select\(\)](#)<sup>p551</sup>, [stepDown\(\)](#)<sup>p494</sup>, and [stepUp\(\)](#)<sup>p494</sup> methods.
- The [value](#)<sup>p492</sup> IDL attribute is in mode [value](#)<sup>p492</sup>.
- The [input](#)<sup>p494</sup> and [change](#)<sup>p494</sup> events [apply](#)<sup>p455</sup>.
- The following content attributes must not be specified and [do not apply](#)<sup>p455</sup> to the element: [accept](#)<sup>p477</sup>, [alt](#)<sup>p480</sup>, [checked](#)<sup>p457</sup>, [dirname](#)<sup>p529</sup>, [formaction](#)<sup>p531</sup>, [formenctype](#)<sup>p532</sup>, [formmethod](#)<sup>p531</sup>, [formnovalidate](#)<sup>p532</sup>, [formtarget](#)<sup>p532</sup>, [height](#)<sup>p397</sup>, [inputmode](#)<sup>p534</sup>, [maxlength](#)<sup>p483</sup>, [minlength](#)<sup>p483</sup>, [multiple](#)<sup>p485</sup>, [pattern](#)<sup>p486</sup>, [placeholder](#)<sup>p490</sup>, [size](#)<sup>p483</sup>, [src](#)<sup>p479</sup>, and [width](#)<sup>p397</sup>.
- The following IDL attributes and methods [do not apply](#)<sup>p455</sup> to the element: [checked](#)<sup>p492</sup>, [files](#)<sup>p493</sup>, [selectionStart](#)<sup>p551</sup>, [selectionEnd](#)<sup>b551</sup>, [selectionDirection](#)<sup>p551</sup>, [valueLow](#)<sup>p493</sup>, and [valueHigh](#)<sup>p493</sup> IDL attributes; [setRangeText\(\)](#)<sup>p551</sup>, and [setSelectionRange\(\)](#)<sup>p551</sup> methods.

#### Example

The following fragment shows part of a calendar application. A user can specify a date and time for a meeting (in his local time zone, probably, though the user agent can allow the user to change that), and since the submitted data includes the time-zone offset, the application can ensure that the meeting is shown at the correct time regardless of the time zones used by all the participants.

```
<fieldset>
 <legend>Add Meeting</legend>
 <p><label>Meeting name: <input type="text" name="meeting.label"></label>
 <p><label>Meeting time: <input type="datetime" name="meeting.start"></label>
</fieldset>
```

Had the application used the [datetime-local](#)<sup>p468</sup> type instead, the calendar application would have also had to explicitly determine which time zone the user intended.

For events where the precise time is to vary as the user travels (e.g. "celebrate the new year!"), and for recurring events that are to stay at the same time for a specific geographic location even though that location may go in and out of daylight savings time (e.g. "bring the kid to school"), the [datetime-local](#)<sup>p468</sup> type combined with a [select](#)<sup>p498</sup> element (or other similar control) to pick the specific geographic location to which to anchor the time would be more appropriate.

#### 4.10.5.1.8 Date state (`type=date`)

When an [input](#)<sup>p452</sup> element's [type](#)<sup>p454</sup> attribute is in the [Date](#)<sup>p464</sup> state, the rules in this section apply.

The [input](#)<sup>p452</sup> element [represents](#)<sup>p111</sup> a control for setting the element's [value](#)<sup>p527</sup> to a string representing a specific [date](#)<sup>p67</sup>.

If the element is [mutable](#)<sup>p527</sup>, the user agent should allow the user to change the [date](#)<sup>p67</sup> represented by its [value](#)<sup>p527</sup>, as obtained [date](#)<sup>p68</sup> from it. User agents must not allow the user to set the [value](#)<sup>p527</sup> to a non-empty string that is not a [valid date string](#)<sup>p67</sup>. If the provides a user interface for selecting a [date](#)<sup>p67</sup>, then the [value](#)<sup>p527</sup> must be set to a [valid date string](#)<sup>p67</sup> representing the user's sel agents should allow the user to set the [value](#)<sup>p527</sup> to the empty string.

Spec bugs: 15114		
Support:		
	Chrome	20+
	IE	None
	Chrome for Android	40+
	Firefox	None
	iOS Safari	5.0-5.1+
	Android Browser	4.4+
	UC Browser for Android	9.9+
	Opera Mini	None

	Opera	9+
	IE Mobile	None
	Firefox for Android	None
Source: caniuse.com		

**Constraint validation:** While the user interface describes input that the user agent cannot convert to a [valid date string](#)<sup>p67</sup>, the control is [suffering from bad input](#)<sup>p553</sup>.

**Note** See the [introduction section](#)<sup>p446</sup> for a discussion of the difference between the input format and submission format for date, time, and number form controls, and the [implementation notes](#)<sup>p482</sup> regarding localization of form controls.

The [value](#)<sup>p457</sup> attribute, if specified and not empty, must have a value that is a [valid date string](#)<sup>p67</sup>.

The [value sanitization algorithm](#)<sup>p456</sup> is as follows: If the [value](#)<sup>p527</sup> of the element is not a [valid date string](#)<sup>p67</sup>, then set it to the empty string instead.

The [min](#)<sup>p487</sup> attribute, if specified, must have a value that is a [valid date string](#)<sup>p67</sup>. The [max](#)<sup>p487</sup> attribute, if specified, must have a value that is a [valid date string](#)<sup>p67</sup>.

The [step](#)<sup>p488</sup> attribute is expressed in days. The [step scale factor](#)<sup>p488</sup> is 86,400,000 (which converts the days to milliseconds, as used in the other algorithms). The [default step](#)<sup>p488</sup> is 1 day.

When the element is [suffering from a step mismatch](#)<sup>p553</sup>, the user agent may round the element's [value](#)<sup>p527</sup> to the nearest [date](#)<sup>p67</sup> for which the element would not [suffer from a step mismatch](#)<sup>p553</sup>.

The [algorithm to convert a string to a number](#)<sup>p456</sup>, given a string [input](#), is as follows: If [parsing a date](#)<sup>p68</sup> from [input](#) results in an error, then return an error; otherwise, return the number of milliseconds elapsed from midnight UTC on the morning of 1970-01-01 (the time represented by the value "1970-01-01T00:00:00.0Z") to midnight UTC on the morning of the parsed [date](#)<sup>p67</sup>, ignoring leap seconds.

The [algorithm to convert a number to a string](#)<sup>p456</sup>, given a number [input](#), is as follows: Return a [valid date string](#)<sup>p67</sup> that represents the [date](#)<sup>p67</sup> that, in UTC, is current [input](#) milliseconds after midnight UTC on the morning of 1970-01-01 (the time represented by the value "1970-01-01T00:00:00.0Z").

The [algorithm to convert a string to a Date object](#)<sup>p456</sup>, given a string [input](#), is as follows: If [parsing a date](#)<sup>p68</sup> from [input](#) results in an error, then return an error; otherwise, return [a new Date object](#)<sup>p50</sup> representing midnight UTC on the morning of the parsed [date](#)<sup>p67</sup>.

The [algorithm to convert a Date object to a string](#)<sup>p456</sup>, given a [Date](#)<sup>p49</sup> object [input](#), is as follows: Return a [valid date string](#)<sup>p67</sup> that represents the [date](#)<sup>p67</sup> current at the time represented by [input](#) in the UTC time zone.

**Note** See [the note on historical dates](#)<sup>p463</sup> in the [Date and Time](#)<sup>p463</sup> state section.

#### Bookkeeping details

- The following common [input](#)<sup>p452</sup> element content attributes, IDL attributes, and methods [apply](#)<sup>p455</sup> to the element: [autocomplete](#)<sup>p535</sup>, [list](#)<sup>p489</sup>, [max](#)<sup>p487</sup>, [min](#)<sup>p487</sup>, [readonly](#)<sup>p483</sup>, [required](#)<sup>p484</sup>, and [step](#)<sup>p488</sup> content attributes; [list](#)<sup>p494</sup>, [value](#)<sup>p492</sup>, [valueAsDate](#)<sup>p493</sup>, and [valueAsNumber](#)<sup>p493</sup> IDL attributes; [select\(\)](#)<sup>p551</sup>, [stepDown\(\)](#)<sup>p494</sup>, and [stepUp\(\)](#)<sup>p494</sup> methods.
- The [value](#)<sup>p492</sup> IDL attribute is in mode [value](#)<sup>p492</sup>.
- The [input](#)<sup>p494</sup> and [change](#)<sup>p494</sup> events [apply](#)<sup>p455</sup>.
- The following content attributes must not be specified and [do not apply](#)<sup>p455</sup> to the element: [accept](#)<sup>p477</sup>, [alt](#)<sup>p480</sup>, [checked](#)<sup>p457</sup>, [dirname](#)<sup>b529</sup>, [formaction](#)<sup>p531</sup>, [formenctype](#)<sup>p532</sup>, [formmethod](#)<sup>p531</sup>, [formnovalidate](#)<sup>p532</sup>, [formtarget](#)<sup>p532</sup>, [height](#)<sup>p397</sup>, [inputmode](#)<sup>p534</sup>, [maxlength](#)<sup>p483</sup>, [minlength](#)<sup>p483</sup>, [multiple](#)<sup>p485</sup>, [pattern](#)<sup>p486</sup>, [placeholder](#)<sup>p490</sup>, [size](#)<sup>p483</sup>, [src](#)<sup>p479</sup>, and [width](#)<sup>b391</sup>.
- The following IDL attributes and methods [do not apply](#)<sup>p455</sup> to the element: [checked](#)<sup>p492</sup>, [selectionStart](#)<sup>p551</sup>, [selectionEnd](#)<sup>p551</sup>, [selectionDirection](#)<sup>p551</sup>, [valueLow](#)<sup>p493</sup>, and [valueHigh](#)<sup>p493</sup> IDL attributes; [setRangeText\(\)](#)<sup>p551</sup>, and [setSelectionRange\(\)](#)<sup>p551</sup> methods.

#### 4.10.5.1.9 Month state (`type=month`)

When an [input](#)<sup>p452</sup> element's [type](#)<sup>p454</sup> attribute is in the [Month](#)<sup>p465</sup> state, the rules in this section apply.

The [input](#)<sup>p452</sup> element [represents](#)<sup>p111</sup> a control for setting the element's [value](#)<sup>p527</sup> to a string representing a specific [month](#)<sup>p67</sup>.

If the element is [mutable](#)<sup>p527</sup>, the user agent should allow the user to change the [month](#)<sup>p67</sup> represented by its [value](#)<sup>p527</sup>, as obtained by [parsing a month](#)<sup>p67</sup> from it. User agents must not allow the user to set the [value](#)<sup>p527</sup> to a non-empty string that is not a [valid month string](#)<sup>p67</sup>. If the user agent provides a user interface for selecting a [month](#)<sup>p67</sup>, then the [value](#)<sup>p527</sup> must be set to a [valid month string](#)<sup>p67</sup> representing the user's selection. User agents should allow the user to set the [value](#)<sup>p527</sup> to the empty string.

**Constraint validation:** While the user interface describes input that the user agent cannot convert to a [valid month string](#)<sup>p67</sup>, the control is [suffering from bad input](#)<sup>p553</sup>.

**Note** See the [introduction section](#)<sup>p446</sup> for a discussion of the difference between the input format and submission format for date, time, and number form controls, and the [implementation notes](#)<sup>p482</sup> regarding localization of form controls.

The [value](#)<sup>p457</sup> attribute, if specified and not empty, must have a value that is a [valid month string](#)<sup>p67</sup>.

The [value sanitization algorithm](#)<sup>p456</sup> is as follows: If the [value](#)<sup>p527</sup> of the element is not a [valid month string](#)<sup>p67</sup>, then set it to the empty string instead.

The [min](#)<sup>p487</sup> attribute, if specified, must have a value that is a [valid month string](#)<sup>p67</sup>. The [max](#)<sup>p487</sup> attribute, if specified, must have a value that is a [valid month string](#)<sup>p67</sup>.

The [step](#)<sup>p488</sup> attribute is expressed in months. The [step scale factor](#)<sup>p488</sup> is 1 (there is no conversion needed as the algorithms use months). The [default step](#)<sup>p488</sup> is 1 month.

When the element is [suffering from a step mismatch](#)<sup>p553</sup>, the user agent may round the element's [value](#)<sup>p527</sup> to the nearest [month](#)<sup>p67</sup> for which the element would not [suffer from a step mismatch](#)<sup>p553</sup>.

The [algorithm to convert a string to a number](#)<sup>p456</sup>, given a string [input](#), is as follows: If [parsing a month](#)<sup>p67</sup> from [input](#) results in an error, then return an error; otherwise, return the number of months between January 1970 and the parsed [month](#)<sup>p67</sup>.

The [algorithm to convert a number to a string](#)<sup>p456</sup>, given a number [input](#), is as follows: Return a [valid month string](#)<sup>p67</sup> that represents the [month](#)<sup>p67</sup> that has [input](#) months between it and January 1970.

The [algorithm to convert a string to a Date object](#)<sup>p456</sup>, given a string [input](#), is as follows: If [parsing a month](#)<sup>p67</sup> from [input](#) results in an error, then return an error; otherwise, return a new [Date object](#)<sup>p50</sup> representing midnight UTC on the morning of the first day of the parsed [month](#)<sup>p67</sup>.

The [algorithm to convert a Date object to a string](#)<sup>p456</sup>, given a [Date](#)<sup>p49</sup> object [input](#), is as follows: Return a [valid month string](#)<sup>p67</sup> that represents the [month](#)<sup>p67</sup> current at the time represented by [input](#) in the UTC time zone.

#### Bookkeeping details

- The following common [input](#)<sup>p452</sup> element content attributes, IDL attributes, and methods [apply](#)<sup>p455</sup> to the element: [autocomplete](#)<sup>p535</sup>, [list](#)<sup>p489</sup>, [max](#)<sup>p487</sup>, [min](#)<sup>p487</sup>, [readonly](#)<sup>p483</sup>, [required](#)<sup>p484</sup>, and [step](#)<sup>p488</sup> content attributes; [list](#)<sup>p494</sup>, [value](#)<sup>p492</sup>, [valueAsDate](#)<sup>p493</sup>, and [valueAsNumber](#)<sup>p493</sup> IDL attributes; [select\(\)](#)<sup>p551</sup>, [stepDown\(\)](#)<sup>p494</sup>, and [stepUp\(\)](#)<sup>p494</sup> methods.
- The [value](#)<sup>p492</sup> IDL attribute is in mode [value](#)<sup>p492</sup>.
- The [input](#)<sup>p494</sup> and [change](#)<sup>p494</sup> events [apply](#)<sup>p455</sup>.
- The following content attributes must not be specified and [do not apply](#)<sup>p455</sup> to the element: [accept](#)<sup>p477</sup>, [alt](#)<sup>p480</sup>, [checked](#)<sup>p457</sup>, [dirname](#)<sup>p529</sup>, [formaction](#)<sup>p531</sup>, [formenctype](#)<sup>p532</sup>, [formmethod](#)<sup>p531</sup>, [formnovalidate](#)<sup>p532</sup>, [formtarget](#)<sup>p532</sup>, [height](#)<sup>p397</sup>, [inputmode](#)<sup>p534</sup>, [maxlength](#)<sup>p483</sup>, [minlength](#)<sup>p483</sup>, [multiple](#)<sup>p485</sup>, [pattern](#)<sup>p486</sup>, [placeholder](#)<sup>p490</sup>, [size](#)<sup>p483</sup>, [src](#)<sup>p479</sup>, and [width](#)<sup>p397</sup>.
- The following IDL attributes and methods [do not apply](#)<sup>p455</sup> to the element: [checked](#)<sup>p492</sup>, [files](#)<sup>p493</sup>, [selectionStart](#)<sup>p551</sup>, [selectionEnd](#)<sup>p551</sup>, [selectionDirection](#)<sup>p551</sup>, [valueLow](#)<sup>p493</sup>, and [valueHigh](#)<sup>p493</sup> IDL attributes; [setRangeText\(\)](#)<sup>p551</sup>, and [setSelectionRange\(\)](#)<sup>p551</sup> methods.

#### 4.10.5.1.10 Week state ([type=week](#))

When an [input](#)<sup>p452</sup> element's [type](#)<sup>p454</sup> attribute is in the [Week](#)<sup>p466</sup> state, the rules in this section apply.

The [input](#)<sup>p452</sup> element [represents](#)<sup>p111</sup> a control for setting the element's [value](#)<sup>p527</sup> to a string representing a specific [week](#)<sup>p73</sup>.

If the element is [mutable](#)<sup>p527</sup>, the user agent should allow the user to change the [week](#)<sup>p73</sup> represented by its [value](#)<sup>p527</sup>, as obtained by [parsing a week](#)<sup>p74</sup> from it. User agents must not allow the user to set the [value](#)<sup>p527</sup> to a non-empty string that is not a [valid week string](#)<sup>p74</sup>. If the user agent provides a user interface for selecting a [week](#)<sup>p73</sup>, then the [value](#)<sup>p527</sup> must be set to a [valid week string](#)<sup>p74</sup> representing the user's selection. User agents should allow the user to set the [value](#)<sup>p527</sup> to the empty string.

**Constraint validation:** While the user interface describes input that the user agent cannot convert to a [valid week string](#)<sup>p74</sup>, the control is [suffering from bad input](#)<sup>p553</sup>.

**Note** See the [introduction section](#)<sup>p446</sup> for a discussion of the difference between the input format and submission format for date, time, and number form controls, and the [implementation notes](#)<sup>p482</sup> regarding localization of form controls.

The [value](#)<sup>p457</sup> attribute, if specified and not empty, must have a value that is a [valid week string](#)<sup>p74</sup>.

The [value sanitization algorithm](#)<sup>p456</sup> is as follows: If the [value](#)<sup>p527</sup> of the element is not a [valid week string](#)<sup>p74</sup>, then set it to the empty string instead.

The [min](#)<sup>p487</sup> attribute, if specified, must have a value that is a [valid week string](#)<sup>p74</sup>. The [max](#)<sup>p487</sup> attribute, if specified, must have a value that is a [valid week string](#)<sup>p74</sup>.

The `step`<sup>p488</sup> attribute is expressed in weeks. The `step scale factor`<sup>p488</sup> is 604,800,000 (which converts the weeks to milliseconds, as used in the other algorithms). The `default step`<sup>p488</sup> is 1 week. The `default step base`<sup>p488</sup> is -259,200,000 (the start of week 1970-W01).

When the element is `suffering from a step mismatch`<sup>p553</sup>, the user agent may round the element's `value`<sup>p527</sup> to the nearest `week`<sup>p73</sup> for which the element would not `suffer from a step mismatch`<sup>p553</sup>.

The `algorithm to convert a string to a number`<sup>p456</sup>, given a string `input`, is as follows: If `parsing a week string`<sup>p74</sup> from `input` results in an error, then return an error; otherwise, return the number of milliseconds elapsed from midnight UTC on the morning of 1970-01-01 (the time represented by the value "1970-01-01T00:00:00.0Z") to midnight UTC on the morning of the Monday of the parsed `week`<sup>p73</sup>, ignoring leap seconds.

The `algorithm to convert a number to a string`<sup>p456</sup>, given a number `input`, is as follows: Return a `valid week string`<sup>p74</sup> that represents the `week`<sup>p73</sup> that, in UTC, is current `input` milliseconds after midnight UTC on the morning of 1970-01-01 (the time represented by the value "1970-01-01T00:00:00.0Z").

The `algorithm to convert a string to a Date object`<sup>p456</sup>, given a string `input`, is as follows: If `parsing a week`<sup>p74</sup> from `input` results in an error, then return an error; otherwise, return a new `Date` object<sup>p50</sup> representing midnight UTC on the morning of the Monday of the parsed `week`<sup>p73</sup>.

The `algorithm to convert a Date object to a string`<sup>p456</sup>, given a `Date`<sup>p49</sup> object `input`, is as follows: Return a `valid week string`<sup>p74</sup> that represents the `week`<sup>p73</sup> current at the time represented by `input` in the UTC time zone.

#### Bookkeeping details

- The following common `input`<sup>b452</sup> element content attributes, IDL attributes, and methods `apply`<sup>b455</sup> to the element: `autocomplete`<sup>p535</sup>, `list`<sup>b489</sup>, `max`<sup>p487</sup>, `min`<sup>p487</sup>, `readonly`<sup>p483</sup>, `required`<sup>p484</sup>, and `step`<sup>p488</sup> content attributes; `list`<sup>p494</sup>, `value`<sup>p492</sup>, `valueAsDate`<sup>p493</sup>, and `valueAsNumber`<sup>p493</sup> IDL attributes; `select()`<sup>p551</sup>, `stepDown()`<sup>p494</sup>, and `stepUp()`<sup>p494</sup> methods.
- The `value`<sup>b492</sup> IDL attribute is in mode `value`<sup>b492</sup>.
- The `input`<sup>p494</sup> and `change`<sup>p494</sup> events `apply`<sup>b455</sup>.
- The following content attributes must not be specified and `do not apply`<sup>b455</sup> to the element: `accept`<sup>p477</sup>, `alt`<sup>p480</sup>, `checked`<sup>p457</sup>, `dirname`<sup>b529</sup>, `formaction`<sup>p531</sup>, `formenctype`<sup>p533</sup>, `formmethod`<sup>p531</sup>, `formnovalidate`<sup>p532</sup>, `formtarget`<sup>p532</sup>, `height`<sup>p397</sup>, `inputmode`<sup>p534</sup>, `maxlength`<sup>b483</sup>, `minlength`<sup>p483</sup>, `multiple`<sup>p485</sup>, `pattern`<sup>p486</sup>, `placeholder`<sup>p490</sup>, `size`<sup>p483</sup>, `src`<sup>p479</sup>, and `width`<sup>p397</sup>.
- The following IDL attributes and methods `do not apply`<sup>b455</sup> to the element: `checked`<sup>p492</sup>, `files`<sup>p493</sup>, `selectionStart`<sup>p551</sup>, `selectionEnd`<sup>b551</sup>, `selectionDirection`<sup>p551</sup>, `valueLow`<sup>p493</sup>, and `valueHigh`<sup>p493</sup> IDL attributes; `setRangeText()`<sup>p551</sup>, and `setSelectionRange()`<sup>p551</sup> methods.

#### 4.10.5.1.11 Time state (`type=time`)

When an `input`<sup>p452</sup> element's `type`<sup>p454</sup> attribute is in the `Time`<sup>p467</sup> state, the rules in this section apply.

The `input`<sup>p452</sup> element `represents`<sup>b111</sup> a control for setting the element's `value`<sup>p527</sup> to a string representing a specific `time`<sup>p69</sup>.

If the element is `mutable`<sup>b527</sup>, the user agent should allow the user to change the `time`<sup>p69</sup> represented by its `value`<sup>p527</sup>, as obtained by `parsing a time`<sup>p69</sup> from it. User agents must not allow the user to set the `value`<sup>p527</sup> to a non-empty string that is not a `valid time string`<sup>p69</sup>. If the user agent provides a user interface for selecting a `time`<sup>p69</sup>, then the `value`<sup>p527</sup> must be set to a `valid time string`<sup>p69</sup> representing the user's selection. User agents should allow the user to set the `value`<sup>p527</sup> to the empty string.

**Constraint validation:** While the user interface describes input that the user agent cannot convert to a `valid time string`<sup>p69</sup>, the control is `suffering from bad input`<sup>p553</sup>.

**Note** See the `introduction section`<sup>p446</sup> for a discussion of the difference between the input format and submission format for date, time, and number form controls, and the `implementation notes`<sup>p482</sup> regarding localization of form controls.

The `value`<sup>p457</sup> attribute, if specified and not empty, must have a value that is a `valid time string`<sup>p69</sup>.

The `value sanitization algorithm`<sup>p456</sup> is as follows: If the `value`<sup>p527</sup> of the element is not a `valid time string`<sup>p69</sup>, then set it to the empty string instead.

The form control `has a periodic domain`<sup>p486</sup>.

The `min`<sup>p487</sup> attribute, if specified, must have a value that is a `valid time string`<sup>p69</sup>. The `max`<sup>p487</sup> attribute, if specified, must have a value that is a `valid time string`<sup>p69</sup>.

The `step`<sup>p488</sup> attribute is expressed in seconds. The `step scale factor`<sup>p488</sup> is 1000 (which converts the seconds to milliseconds, as used in the other algorithms). The `default step`<sup>p488</sup> is 60 seconds.

When the element is `suffering from a step mismatch`<sup>p553</sup>, the user agent may round the element's `value`<sup>p527</sup> to the nearest `time`<sup>p69</sup> for which the element would not `suffer from a step mismatch`<sup>p553</sup>.

The `algorithm to convert a string to a number`<sup>p456</sup>, given a string `input`, is as follows: If `parsing a time`<sup>p69</sup> from `input` results in an error, then return an error; otherwise, return the number of milliseconds elapsed from midnight to the parsed `time`<sup>p69</sup> on a day with no time changes.

The `algorithm to convert a number to a string`<sup>p456</sup>, given a number `input`, is as follows: Return a `valid time string`<sup>p69</sup> that represents the `time`<sup>p69</sup> that is `input` milliseconds after midnight on a day with no time changes.

The `algorithm to convert a string to a Date object`<sup>p456</sup>, given a string `input`, is as follows: If `parsing a time`<sup>p69</sup> from `input` results in an error, then return an error; otherwise, return a new `Date` object<sup>p50</sup> representing the parsed `time`<sup>p69</sup> in UTC on 1970-01-01.

The `algorithm to convert a Date object to a string`<sup>p456</sup>, given a `Date`<sup>p49</sup> object `input`, is as follows: Return a `valid time string`<sup>p69</sup> that represents the UTC `time`<sup>p69</sup> component that is represented by `input`.

#### Bookkeeping details

- The following common `input`<sup>p452</sup> element content attributes, IDL attributes, and methods `apply`<sup>p455</sup> to the element: `autocomplete`<sup>p535</sup>, `list`<sup>p489</sup>, `max`<sup>p487</sup>, `min`<sup>p487</sup>, `readonly`<sup>p483</sup>, `required`<sup>p484</sup>, and `step`<sup>p488</sup> content attributes; `list`<sup>p494</sup>, `value`<sup>p492</sup>, `valueAsDate`<sup>p493</sup>, and `valueAsNumber`<sup>p493</sup> IDL attributes; `select()`<sup>p551</sup>, `stepDown()`<sup>p494</sup>, and `stepUp()`<sup>p494</sup> methods.
- The `value`<sup>p492</sup> IDL attribute is in mode `value`<sup>p492</sup>.
- The `input`<sup>p494</sup> and `change`<sup>p494</sup> events `apply`<sup>p455</sup>.
- The following content attributes must not be specified and `do not apply`<sup>p455</sup> to the element: `accept`<sup>p477</sup>, `alt`<sup>p480</sup>, `checked`<sup>p457</sup>, `dirname`<sup>p529</sup>, `formaction`<sup>p531</sup>, `formenctype`<sup>p532</sup>, `formmethod`<sup>p531</sup>, `formnovalidate`<sup>p532</sup>, `formtarget`<sup>p532</sup>, `height`<sup>p397</sup>, `inputmode`<sup>p534</sup>, `maxlength`<sup>p483</sup>, `minlength`<sup>p483</sup>, `multiple`<sup>p185</sup>, `pattern`<sup>p486</sup>, `placeholder`<sup>p490</sup>, `size`<sup>p483</sup>, `src`<sup>p479</sup>, and `width`<sup>p397</sup>.
- The following IDL attributes and methods `do not apply`<sup>p455</sup> to the element: `checked`<sup>p492</sup>, `files`<sup>p493</sup>, `selectionStart`<sup>p551</sup>, `selectionEnd`<sup>p551</sup>, `selectionDirection`<sup>p551</sup>, `valueLow`<sup>p493</sup>, and `valueHigh`<sup>p493</sup> IDL attributes; `setRangeText()`<sup>p551</sup>, and `setSelectionRange()`<sup>p551</sup> methods.

#### 4.10.5.1.12 Local Date and Time state (`type=datetime-local`)

When an `input`<sup>p452</sup> element's `type`<sup>p454</sup> attribute is in the `Local Date and Time`<sup>p468</sup> state, the rules in this section apply.

The `input`<sup>p452</sup> element `represents`<sup>p111</sup> a control for setting the element's `value`<sup>p527</sup> to a string representing a `local date and time`<sup>p70</sup>, with no time-zone offset information.

If the element is `mutable`<sup>p527</sup>, the user agent should allow the user to change the `date and time`<sup>p70</sup> represented by its `value`<sup>p527</sup>, as obtained by `parsing a date and time`<sup>p70</sup> from it. User agents must not allow the user to set the `value`<sup>p527</sup> to a non-empty string that is not a `valid normalised local date and time string`<sup>p70</sup>. If the user agent provides a user interface for selecting a `local date and time`<sup>p70</sup>, then the `value`<sup>p527</sup> must be set to a `valid normalised local date and time string`<sup>p70</sup> representing the user's selection. User agents should allow the user to set the `value`<sup>p527</sup> to the empty string.

**Constraint validation:** While the user interface describes input that the user agent cannot convert to a `valid normalised local date and time string`<sup>p70</sup>, the control is `suffering from bad input`<sup>p553</sup>.

**Note** See the `introduction section`<sup>p446</sup> for a discussion of the difference between the `input` format and submission format for date, time, and number form controls, and the `implementation notes`<sup>p482</sup> regarding localization of form controls.

The `value`<sup>p457</sup> attribute, if specified and not empty, must have a value that is a `valid local date and time string`<sup>p70</sup>.

The `value sanitization algorithm`<sup>p456</sup> is as follows: If the `value`<sup>p527</sup> of the element is a `valid local date and time string`<sup>p70</sup>, then set it to a `valid normalised local date and time string`<sup>p70</sup> representing the same date and time; otherwise, set it to the empty string instead.

The `min`<sup>p487</sup> attribute, if specified, must have a value that is a `valid local date and time string`<sup>p70</sup>. The `max`<sup>p487</sup> attribute, if specified, must have a value that is a `valid local date and time string`<sup>p70</sup>.

The `step`<sup>p488</sup> attribute is expressed in seconds. The `step scale factor`<sup>p488</sup> is 1000 (which converts the seconds to milliseconds, as used in the other algorithms). The `default step`<sup>p488</sup> is 60 seconds.

When the element is [suffering from a step mismatch](#)<sup>p553</sup>, the user agent may round the element's [value](#)<sup>p527</sup> to the nearest [local date and time](#)<sup>p70</sup> for which the element would not [suffer from a step mismatch](#)<sup>p553</sup>.

The [algorithm to convert a string to a number](#)<sup>p456</sup>, given a string *input*, is as follows: If [parsing a date and time](#)<sup>p70</sup> from *input* results in an error, then return an error; otherwise, return the number of milliseconds elapsed from midnight on the morning of 1970-01-01 (the time represented by the value "1970-01-01T00:00:00.0") to the parsed [local date and time](#)<sup>p70</sup>, ignoring leap seconds.

The [algorithm to convert a number to a string](#)<sup>p456</sup>, given a number *input*, is as follows: Return a [valid normalised local date and time string](#)<sup>p70</sup> that represents the date and time that is *input* milliseconds after midnight on the morning of 1970-01-01 (the time represented by the value "1970-01-01T00:00:00.0").

**Note** See [the note on historical dates](#)<sup>p463</sup> in the [Date and Time](#)<sup>p463</sup> state section.

#### Bookkeeping details

- The following common [input](#)<sup>p452</sup> element content attributes, IDL attributes, and methods [apply](#)<sup>p456</sup> to the element: [autocomplete](#)<sup>p535</sup>, [list](#)<sup>p489</sup>, [max](#)<sup>p487</sup>, [min](#)<sup>p487</sup>, [readonly](#)<sup>p483</sup>, [required](#)<sup>p484</sup>, and [step](#)<sup>p488</sup> content attributes; [list](#)<sup>p494</sup>, [value](#)<sup>p492</sup>, and [valueAsNumber](#)<sup>p493</sup> IDL attributes; [select\(\)](#)<sup>p551</sup>, [stepDown\(\)](#)<sup>p494</sup>, and [stepUp\(\)](#)<sup>p494</sup> methods.
- The [value](#)<sup>p492</sup> IDL attribute is in mode [value](#)<sup>p492</sup>.
- The [input](#)<sup>p494</sup> and [change](#)<sup>b494</sup> events [apply](#)<sup>p455</sup>.
- The following content attributes must not be specified and [do not apply](#)<sup>p455</sup> to the element: [accept](#)<sup>p477</sup>, [alt](#)<sup>p480</sup>, [checked](#)<sup>p457</sup>, [dirname](#)<sup>p529</sup>, [formaction](#)<sup>p531</sup>, [formenctype](#)<sup>p532</sup>, [formmethod](#)<sup>p531</sup>, [formnovalidate](#)<sup>p532</sup>, [formtarget](#)<sup>p532</sup>, [height](#)<sup>p397</sup>, [inputmode](#)<sup>p534</sup>, [maxlength](#)<sup>p483</sup>, [minlength](#)<sup>p483</sup>, [multiple](#)<sup>p485</sup>, [pattern](#)<sup>p486</sup>, [placeholder](#)<sup>p490</sup>, [size](#)<sup>p483</sup>, [src](#)<sup>p479</sup>, and [width](#)<sup>p397</sup>.
- The following IDL attributes and methods [do not apply](#)<sup>p455</sup> to the element: [checked](#)<sup>p492</sup>, [files](#)<sup>p493</sup>, [selectionStart](#)<sup>p551</sup>, [selectionEnd](#)<sup>p551</sup>, [selectionDirection](#)<sup>p551</sup>, [valueAsDate](#)<sup>p493</sup>, [valueLow](#)<sup>p493</sup>, and [valueHigh](#)<sup>p493</sup> IDL attributes; [setRangeText\(\)](#)<sup>p551</sup>, and [setSelectionRange\(\)](#)<sup>p551</sup> methods.

#### Example

The following example shows part of a flight booking application. The application uses an [input](#)<sup>p452</sup> element with its [type](#)<sup>p454</sup> attribute set to [datetime-local](#)<sup>p468</sup>, and it then interprets the given date and time in the time zone of the selected airport.

```
<fieldset>
<legend>Destination</legend>
<p><label>Airport: <input type="text" name="to" list="airports"></label></p>
<p><label>Departure time: <input type="datetime-local" name="totime" step="3600"></label></p>
</fieldset>
<datalist id="airports">
<option value="ATL" label="Atlanta">
<option value="MEM" label="Memphis">
<option value="LHR" label="London Heathrow">
<option value="LAX" label="Los Angeles">
<option value="FRA" label="Frankfurt">
</datalist>
```

If the application instead used the [datetime](#)<sup>p463</sup> type, then the user would have to work out the time-zone conversions himself, which is clearly not a good user experience!

#### 4.10.5.1.13 Number state (*type=number*)

Source: [caniuse.com](#)

When an [input](#)<sup>p452</sup> element's [type](#)<sup>p454</sup> attribute is in the [Number](#)<sup>p469</sup> state, the rules in this section apply.

The [input](#)<sup>p452</sup> element [represents](#)<sup>b111</sup> a control for setting the element's [value](#)<sup>b527</sup> to a string representing a number.

If the element is [mutable](#)<sup>b527</sup>, the user agent should allow the user to change the number represented by its [value](#)<sup>p527</sup>, as obtained [rules for parsing floating-point number values](#)<sup>p62</sup> to it. User agents must not allow the user to set the [value](#)<sup>p527</sup> to a non-empty string [valid floating-point number](#)<sup>p61</sup>. If the user agent provides a user interface for selecting a number, then the [value](#)<sup>p527</sup> must be set to [representation of the number representing the user's selection as a floating-point number](#)<sup>p62</sup>. User agents should allow the user to set the [value](#)<sup>p527</sup> to the empty string.

**Constraint validation:** While the user interface describes input that the user agent cannot convert to a [valid floating-point number](#)<sup>p527</sup>, the control is suffering from bad input<sup>p553</sup>.

**Note** This specification does not define what user interface user agents are to use; user agent vendors are encouraged to consider what would best serve their users' needs. For example, a user agent in Persian or Arabic markets might support Persian and Arabic numeric input (converting it to the format required for submission as described above). Similarly, a user agent designed for Romans might display the value in Roman numerals rather than in decimal; or (more realistically) a user agent designed for the French market might display the value with apostrophes between thousands and commas before the decimals, and allow the user to enter a value in that manner, internally converting it to the submission format described above.

The `value`<sup>p457</sup> attribute, if specified and not empty, must have a value that is a [valid floating-point number](#)<sup>p61</sup>.

**The `value` sanitization algorithm**<sup>p456</sup> is as follows: If the `value`<sup>p527</sup> of the element is not a [valid floating-point number](#)<sup>p61</sup>, then set it to the empty string instead.

The `min`<sup>p487</sup> attribute, if specified, must have a value that is a [valid floating-point number](#)<sup>p61</sup>. The `max`<sup>p487</sup> attribute, if specified, must have a value that is a [valid floating-point number](#)<sup>p61</sup>.

The `step scale factor`<sup>p488</sup> is 1. The `default step`<sup>p488</sup> is 1 (allowing only integers to be selected by the user, unless the `step base`<sup>p488</sup> has a non-integer value).

When the element is [suffering from a step mismatch](#)<sup>p553</sup>, the user agent may round the element's `value`<sup>p527</sup> to the nearest number for which the element would not [suffer from a step mismatch](#)<sup>p553</sup>. If there are two such numbers, user agents are encouraged to pick the one nearest positive infinity.

**The `algorithm to convert a string to a number`**<sup>p456</sup>, given a string `input`, is as follows: If applying the [rules for parsing floating-point number values](#)<sup>p62</sup> to `input` results in an error, then return an error; otherwise, return the resulting number.

**The `algorithm to convert a number to a string`**<sup>p456</sup>, given a number `input`, is as follows: Return a [valid floating-point number](#)<sup>p61</sup> that represents `input`.

#### Bookkeeping details

- The following common `input`<sup>p452</sup> element content attributes, IDL attributes, and methods `apply`<sup>p455</sup> to the element: `autocomplete`<sup>p535</sup>, `list`<sup>p489</sup>, `max`<sup>p487</sup>, `min`<sup>p487</sup>, `placeholder`<sup>p490</sup>, `readonly`<sup>p483</sup>, `required`<sup>p484</sup>, and `step`<sup>p488</sup> content attributes; `list`<sup>p494</sup>, `value`<sup>p492</sup>, and `valueAsNumber`<sup>p492</sup> IDL attributes; `select()`<sup>p551</sup>, `stepDown()`<sup>p494</sup>, and `stepUp()`<sup>p494</sup> methods.
- The `value`<sup>p492</sup> IDL attribute is in mode `value`<sup>p492</sup>.
- The `input`<sup>p494</sup> and `change`<sup>p494</sup> events `apply`<sup>p455</sup>.
- The following content attributes must not be specified and [do not apply](#)<sup>p455</sup> to the element: `accept`<sup>p477</sup>, `alt`<sup>p480</sup>, `checked`<sup>p457</sup>, `dirname`<sup>p529</sup>, `formaction`<sup>p531</sup>, `formenctype`<sup>p532</sup>, `formmethod`<sup>p531</sup>, `formnovalidate`<sup>p532</sup>, `formtarget`<sup>p532</sup>, `height`<sup>p397</sup>, `inputmode`<sup>p534</sup>, `maxlength`<sup>p483</sup>, `minlength`<sup>p483</sup>, `multiple`<sup>p485</sup>, `pattern`<sup>p486</sup>, `size`<sup>p483</sup>, `src`<sup>p479</sup>, and `width`<sup>p397</sup>.
- The following IDL attributes and methods [do not apply](#)<sup>p455</sup> to the element: `checked`<sup>p492</sup>, `files`<sup>p493</sup>, `selectionStart`<sup>p551</sup>, `selectionEnd`<sup>p551</sup>, `selectionDirection`<sup>p551</sup>, `valueAsDate`<sup>p493</sup>, `valueLow`<sup>p493</sup>, and `valueHigh`<sup>p493</sup> IDL attributes; `setRangeText()`<sup>p551</sup>, and `setSelectionRange()`<sup>p551</sup> methods.

#### Example

Here is an example of using a numeric input control:

```
<label>How much do you want to charge? $<input type=number min=0 step=0.01 name=price></label>
```

As described above, a user agent might support numeric input in the user's local format, converting it to the format required for submission as described above. This might include handling grouping separators (as in "872,000,000,000") and various decimal separators (such as "3,99" vs "3.99") or using local digits (such as those in Arabic, Devanagari, Persian, and Thai).

**Note** The `type=number` state is not appropriate for input that happens to only consist of numbers but isn't strictly speaking a number. For example, it would be inappropriate for credit card numbers or US postal codes. A simple way of determining whether to use `type=number` is to consider whether it would make sense for the input control to have a spinbox interface (e.g. with "up" and "down" arrows). Getting a credit card number wrong by 1 in the last digit isn't a minor mistake, it's as wrong as getting every digit incorrect. So it would not make sense for the user to select a credit card number using "up" and "down" buttons. When a spinbox interface is not appropriate, `type=text` is probably the right choice (possibly with a `pattern`<sup>p486</sup> attribute).

#### 4.10.5.1.14 Range state (`type=range`)

When an `input`<sup>p452</sup> element's `type`<sup>p454</sup> attribute is in the `Range`<sup>p470</sup> state, the rules in this section apply.

Support:

Source: caniuse.com

How the [Range](#)<sup>p470</sup> state operates depends on whether the [multiple](#)<sup>p485</sup> attribute is specified or not.

#### ↳ When the [multiple](#)<sup>p485</sup> attribute is not specified on the element

The [input](#)<sup>p452</sup> element [represents](#)<sup>p111</sup> a control for setting the element's [value](#)<sup>p527</sup> to a string representing a number, but with the caveat that the exact value is not important, letting UAs provide a simpler interface than they do for the [Number](#)<sup>p469</sup> state.

If the element is [mutable](#)<sup>p527</sup>, the user agent should allow the user to change the number represented by its [value](#)<sup>p527</sup>, as obtained from applying the [rules for parsing floating-point number values](#)<sup>p62</sup> to it. User agents must not allow the user to set the [value](#)<sup>p527</sup> to a string that is not a [valid floating-point number](#)<sup>p61</sup>. If the user agent provides a user interface for selecting a number, then the [value](#)<sup>p527</sup> must be set to a [best representation of the number representing the user's selection as a floating-point number](#)<sup>p62</sup>. User agents must not allow the user to set the [value](#)<sup>p527</sup> to the empty string.

**Constraint validation:** While the user interface describes input that the user agent cannot convert to a [valid floating-point number](#)<sup>p61</sup>, the control is [suffering from bad input](#)<sup>p553</sup>.

The [value](#)<sup>p457</sup> attribute, if specified, must have a value that is a [valid floating-point number](#)<sup>p61</sup>.

**The value sanitization algorithm**<sup>p456</sup> is as follows: If the [value](#)<sup>p527</sup> of the element is not a [valid floating-point number](#)<sup>p61</sup>, then set it to the [best representation, as a floating-point number](#)<sup>p62</sup>, of the [default value](#)<sup>p471</sup>.

The **default value** is the [minimum](#)<sup>p487</sup> plus half the difference between the [minimum](#)<sup>p487</sup> and the [maximum](#)<sup>p487</sup>, unless the [maximum](#)<sup>p487</sup> is less than the [minimum](#)<sup>p487</sup>, in which case the [default value](#)<sup>p471</sup> is the [minimum](#)<sup>p487</sup>.

When the element is [suffering from an underflow](#)<sup>p553</sup>, the user agent must set the element's [value](#)<sup>p527</sup> to the [best representation, as a floating-point number](#)<sup>p62</sup>, of the [minimum](#)<sup>p487</sup>.

When the element is [suffering from an overflow](#)<sup>p553</sup>, if the [maximum](#)<sup>p487</sup> is not less than the [minimum](#)<sup>p487</sup>, the user agent must set the element's [value](#)<sup>p527</sup> to a [valid floating-point number](#)<sup>p61</sup> that represents the [maximum](#)<sup>p487</sup>.

When the element is [suffering from a step mismatch](#)<sup>p553</sup>, the user agent must round the element's [value](#)<sup>p527</sup> to the nearest number for which the element would not [suffer from a step mismatch](#)<sup>p553</sup>, and which is greater than or equal to the [minimum](#)<sup>p487</sup>, and, if the [maximum](#)<sup>p487</sup> is not less than the [minimum](#)<sup>p487</sup>, which is less than or equal to the [maximum](#)<sup>p487</sup>, if there is a number that matches these constraints. If two numbers match these constraints, then user agents must use the one nearest to positive infinity.

**Example** For example, the markup `<input type="range" min=0 max=100 step=20 value=50>` results in a range control whose initial value is 60.

**Example** Here is an example of a range control using an autocomplete list with the [list](#)<sup>p489</sup> attribute. This could be useful if there are values along the full range of the control that are especially important, such as preconfigured light levels or typical speed limits in a range control used as a speed control. The following markup fragment:

```
<input type="range" min="-100" max="100" value="0" step="10" name="power" list="powers">
<datalist id="powers">
 <option value="0">
 <option value="-30">
 <option value="30">
 <option value="++50">
</datalist>
```

...with the following style sheet applied:

```
input { height: 75px; width: 49px; background: #D5CCBB; color: black; }
```

...might render as:

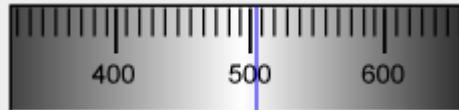

Note how the UA determined the orientation of the control from the ratio of the style-sheet-specified height and width properties. The colours were similarly derived from the style sheet. The tick marks, however, were derived from the markup. In particular, the `step`<sup>p488</sup> attribute has not affected the placement of tick marks, the UA deciding to only use the author-specified completion values and then adding longer tick marks at the extremes.

Note also how the invalid value `++50` was completely ignored.

**Example** For another example, consider the following markup fragment:

```
<input name=x type=range min=100 max=700 step=9.09090909 value=509.090909>
```

A user agent could display in a variety of ways, for instance:

Or, alternatively, for instance:

The user agent could pick which one to display based on the dimensions given in the style sheet. This would allow it to maintain the same resolution for the tick marks, despite the differences in width.

**Example** Finally, here is an example of a range control with two labeled values:

```
<input type="range" name="a" list="a-values">
<datalist id="a-values">
 <option value="10" label="Low">
 <option value="90" label="High">
</datalist>
```

With styles that make the control draw vertically, it might look as follows:

#### ↳ When the `multiple`<sup>p485</sup> attribute is specified on the element

The `input`<sup>p452</sup> element [represents](#)<sup>p111</sup> a control for setting the element's [values](#)<sup>p527</sup> to two strings representing numbers, but with the caveat that the exact values are not important, enabling UAs provide a graphical interface rather than requiring the user to type the numbers directly.

If the element is [mutable](#)<sup>p527</sup>, the user agent should allow the user to change either the first or second number represented by its [values](#)<sup>p527</sup>, as obtained from applying the [rules for parsing floating-point number values](#)<sup>p62</sup> to them, and ensuring that the first value is never larger than the second value. User agents must not allow the user to set either the first or second of the [values](#)<sup>p527</sup> to a string that is not a [valid floating-point number](#)<sup>p61</sup>. If the user agent provides a user interface for selecting a number, then these [values](#)<sup>p527</sup> must be set to the [best representations of the numbers representing the user's selections as floating-point numbers](#)<sup>p62</sup>. User agents must not allow the user to set the [values](#)<sup>p527</sup> to the empty string.

**Constraint validation:** While the user interface describes input that the user agent cannot convert to a pair of [valid floating-point numbers](#)<sup>p61</sup>, the control is [suffering from bad input](#)<sup>p53</sup>.

The [value](#)<sup>p457</sup> attribute, if specified, must have a value that is a pair of [valid floating-point numbers](#)<sup>p61</sup> separated by a single U+002C COMMA character (,).

The [value sanitization algorithm](#)<sup>p456</sup> is as follows:

1. Split on commas<sup>p81</sup> the element's [value](#)<sup>p527</sup>.
2. If there are not exactly two values, or if either value is not a [valid floating-point number](#)<sup>p61</sup>, then let the element's [values](#)<sup>p527</sup> be a pair of values consisting of [a best representation, as a floating-point number](#)<sup>p62</sup>, of the element's [minimum](#)<sup>p487</sup> and the element's [maximum](#)<sup>p487</sup>, with the smaller value first.
3. Otherwise, let the element's [values](#)<sup>p527</sup> be the two values, with the smaller value first.
4. Let the element's [value](#)<sup>p527</sup> be the result of concatenating the element's [values](#)<sup>p527</sup>, separating them by a single U+002C COMMA character (,), with the lower value coming first.

Whenever the user changes the element's [values](#)<sup>p527</sup>, the user agent must set the element's [value](#)<sup>p527</sup> to the result of concatenating the element's [values](#)<sup>p527</sup>, separating them by a single U+002C COMMA character (,), with the lower value coming first.

When the element is [suffering from an underflow](#)<sup>p553</sup>, the user agent must set either of the element's [values](#)<sup>p527</sup> that represent values less than the [minimum](#)<sup>p487</sup> to the [best representation, as a floating-point number](#)<sup>p62</sup>, of the [minimum](#)<sup>p487</sup>.

When the element is [suffering from an overflow](#)<sup>p553</sup>, if the [maximum](#)<sup>p487</sup> is not less than the [minimum](#)<sup>p487</sup>, the user agent must set either of the element's [values](#)<sup>p527</sup> that represent values greater than the [maximum](#)<sup>p487</sup> to a [valid floating-point number](#)<sup>p61</sup> that represents the [maximum](#)<sup>p487</sup>.

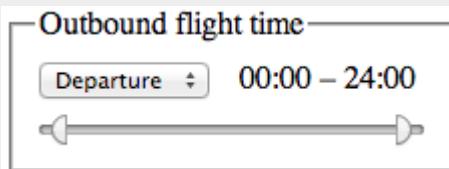

When the element is [suffering from a step mismatch](#)<sup>p553</sup>, the user agent must round the values represented by the element's [values](#)<sup>p527</sup> to, in each case, the nearest number for which the element would not [suffer from a step mismatch](#)<sup>p553</sup>, and which is greater than or equal to the [minimum](#)<sup>p487</sup>, and, if the [maximum](#)<sup>p487</sup> is not less than the [minimum](#)<sup>p487</sup>, which is less than or equal to the [maximum](#)<sup>p487</sup>, if there is a number that matches these constraints. If two numbers match these constraints, then user agents must use the one nearest to positive infinity.

Whenever the user agent changes the element's [values](#)<sup>p527</sup> according to the three previous paragraphs, the user agent must set the element's [value](#)<sup>p527</sup> to the result of concatenating the element's [values](#)<sup>p527</sup>, separating them by a single U+002C COMMA character (,), with the lower value coming first.

**Example** Consider a user interface that filters possible flights by departure and arrival time:

```
<form ...>
 <fieldset>
 <legend>Outbound flight time</legend>
 <select ...>
 <option>Departure
 <option>Arrival
 </select>
 <p><output name=o1>00:00</output> - <output name=o2>24:00</output></p>
 <input type=range multiple min=0 max=24 value=0,24 step=1.0 ...
 oninput="o1.value = valueLow + ':00'; o2.value = valueHigh + ':00'">
 </fieldset>
 ...
</form>
```

With appropriate styling, this might look like:

When the `multiple`<sup>p485</sup> attribute is set or removed, the user agent must run the [value sanitization algorithm](#)<sup>p456</sup>.

**Note** In this state, the range and step constraints are enforced even during user input, and there is no way to set the value to the empty string.

The `min`<sup>p487</sup> attribute, if specified, must have a value that is a [valid floating-point number](#)<sup>p61</sup>. The `default minimum`<sup>p487</sup> is 0. The `max`<sup>p487</sup> attribute, if specified, must have a value that is a [valid floating-point number](#)<sup>p61</sup>. The `default maximum`<sup>p487</sup> is 100.

The `step scale factor`<sup>p488</sup> is 1. The `default step`<sup>p488</sup> is 1 (allowing only integers, unless the `min`<sup>p487</sup> attribute has a non-integer value).

The [algorithm to convert a string to a number](#)<sup>p456</sup>, given a string `input`, is as follows: If applying the [rules for parsing floating-point number values](#)<sup>p62</sup> to `input` results in an error, then return an error; otherwise, return the resulting number.

The [algorithm to convert a number to a string](#)<sup>p456</sup>, given a number `input`, is as follows: Return the best representation, as a floating-point number<sup>p62</sup>, of `input`.

#### Bookkeeping details

- The following common `input`<sup>p452</sup> element content attributes, IDL attributes, and methods `apply`<sup>p455</sup> to the element: `autocomplete`<sup>p535</sup>, `list`<sup>p489</sup>, `max`<sup>p487</sup>, `min`<sup>p487</sup>, `multiple`<sup>p485</sup>, and `step`<sup>p488</sup> content attributes; `list`<sup>p494</sup>, `value`<sup>p492</sup>, and `valueAsNumber`<sup>p493</sup> IDL attributes; `stepDown()`<sup>p494</sup> and `stepUp()`<sup>p494</sup> methods.
- The following common `input`<sup>p452</sup> IDL attribute `applies`<sup>p455</sup> to the element if the `multiple`<sup>p485</sup> content attribute is not specified: `valueAsNumber`<sup>p493</sup>.
- The following common `input`<sup>p452</sup> IDL attributes `apply`<sup>p455</sup> to the element if the `multiple`<sup>p485</sup> content attribute is specified: `valueLow`<sup>p493</sup> and `valueHigh`<sup>p493</sup>.
- The `value`<sup>p492</sup> IDL attribute is in mode `value`<sup>p492</sup>.
- The `input`<sup>p494</sup> and `change`<sup>p494</sup> events `apply`<sup>p455</sup>.
- The following content attributes must not be specified and `do not apply`<sup>p455</sup> to the element: `accept`<sup>p477</sup>, `alt`<sup>p480</sup>, `checked`<sup>p457</sup>, `dirname`<sup>p529</sup>, `formaction`<sup>p531</sup>, `formenctype`<sup>p532</sup>, `formmethod`<sup>p531</sup>, `formnovalidate`<sup>p532</sup>, `formtarget`<sup>p532</sup>, `height`<sup>p397</sup>, `inputmode`<sup>p534</sup>, `maxlength`<sup>p483</sup>, `minlength`<sup>p483</sup>, `pattern`<sup>p486</sup>, `placeholder`<sup>p490</sup>, `readonly`<sup>p483</sup>, `required`<sup>p484</sup>, `size`<sup>p483</sup>, `src`<sup>p479</sup>, and `width`<sup>p397</sup>.
- The following IDL attributes and methods `do not apply`<sup>p455</sup> to the element: `checked`<sup>p492</sup>, `files`<sup>p493</sup>, `selectionStart`<sup>p551</sup>, `selectionEnd`<sup>p551</sup>, `selectionDirection`<sup>p551</sup>, `valueAsDate`<sup>p493</sup>, `valueLow`<sup>p493</sup>, and `valueHigh`<sup>p493</sup> IDL attributes; `select()`<sup>p551</sup>, `setRangeText()`<sup>p551</sup>, and `setSelectionRange()`<sup>p551</sup> methods.
- The following common `input`<sup>p452</sup> IDL attributes `do not apply`<sup>p455</sup> to the element if the `multiple`<sup>p485</sup> content attribute is not specified: `valueLow`<sup>p493</sup> and `valueHigh`<sup>p493</sup>.
- The following common `input`<sup>p452</sup> IDL attribute `does not apply`<sup>p455</sup> to the element if the `multiple`<sup>p485</sup> content attribute is specified: `valueAsNumber`<sup>p493</sup>.

#### 4.10.5.1.15 Colour state (`type=color`)

When an `input`<sup>p452</sup> element's `type`<sup>p454</sup> attribute is in the [Colour](#)<sup>p474</sup> state, the rules in this section apply.

The `input`<sup>p452</sup> element [represents](#)<sup>p111</sup> a colour well control, for setting the element's `value`<sup>p527</sup> to a string representing a [simple colour](#)<sup>p78</sup>.

**Note** In this state, there is always a colour picked, and there is no way to set the value to the empty string.

If the element is [mutable](#)<sup>p527</sup>, the user agent should allow the user to change the colour represented by its `value`<sup>p527</sup>, as obtained from the [rules for parsing simple colour values](#)<sup>p78</sup> to it. User agents must not allow the user to set the `value`<sup>p527</sup> to a string that is not a [valid simple colour](#)<sup>p78</sup>. If the user agent provides a user interface for selecting a colour, then the `value`<sup>p527</sup> must be set to the result of using the [rules for serialising simple colour values](#)<sup>p79</sup> to the user's selection. User agents must not allow the user to set the `value`<sup>p527</sup> to the empty string.

Source: caniuse.com

**Constraint validation:** While the user interface describes input that the user agent cannot convert to a [valid lowercase simple colour](#)<sup>p78</sup>, the control is suffering from bad input<sup>p553</sup>.

The `value`<sup>p457</sup> attribute, if specified and not empty, must have a value that is a [valid simple colour](#)<sup>p78</sup>.

The [value sanitization algorithm](#)<sup>p456</sup> is as follows: If the `value`<sup>p527</sup> of the element is a [valid simple colour](#)<sup>p78</sup>, then set it to the `value`<sup>p527</sup> of the element converted to ASCII lowercase<sup>p58</sup>; otherwise, set it to the string "#000000".

#### Bookkeeping details

- The following common `input`<sup>p452</sup> element content attributes and IDL attributes `apply`<sup>p455</sup> to the element: `autocomplete`<sup>p535</sup> and `list`<sup>p489</sup> content attributes; `list`<sup>p494</sup> and `value`<sup>p492</sup> IDL attributes; `select()`<sup>p551</sup> method.
- The `value`<sup>p492</sup> IDL attribute is in mode `value`<sup>p492</sup>.
- The `input`<sup>p494</sup> and `change`<sup>p494</sup> events `apply`<sup>p455</sup>.
- The following content attributes must not be specified and `do not apply`<sup>p455</sup> to the element: `accept`<sup>p477</sup>, `alt`<sup>p480</sup>, `checked`<sup>p457</sup>, `dirname`<sup>p529</sup>, `formaction`<sup>p531</sup>, `formenctype`<sup>p532</sup>, `formmethod`<sup>p531</sup>, `formnovalidate`<sup>p532</sup>, `formtarget`<sup>p532</sup>, `height`<sup>p397</sup>, `inputmode`<sup>p534</sup>, `max`<sup>p487</sup>, `maxlength`<sup>p483</sup>, `min`<sup>p487</sup>, `minlength`<sup>p483</sup>, `multiple`<sup>p485</sup>, `pattern`<sup>p486</sup>, `placeholder`<sup>p490</sup>, `readonly`<sup>p483</sup>, `required`<sup>p484</sup>, `size`<sup>p483</sup>, `src`<sup>p479</sup>, `step`<sup>p488</sup>, and `width`<sup>p397</sup>.

- The following IDL attributes and methods do not apply<sup>p455</sup> to the element: checked<sup>p492</sup>, files<sup>p493</sup>, selectionStart<sup>p551</sup>, selectionEnd<sup>p551</sup>, selectionDirection<sup>p551</sup>, valueAsDate<sup>p493</sup>, valueAsNumber<sup>p493</sup>, valueLow<sup>p493</sup>, and valueHigh<sup>p493</sup> IDL attributes; setRangeText()<sup>p551</sup>, setSelectionRange()<sup>p551</sup>, stepDown()<sup>p494</sup>, and stepUp()<sup>p494</sup> methods.

#### 4.10.5.1.16 Checkbox state (`type=checkbox`)

When an input<sup>p452</sup> element's type<sup>p454</sup> attribute is in the Checkbox<sup>p475</sup> state, the rules in this section apply.

The input<sup>p452</sup> element represents<sup>p111</sup> a two-state control that represents the element's checkedness<sup>p527</sup> state. If the element's checkedness<sup>p527</sup> state is true, the control represents a positive selection, and if it is false, a negative selection. If the element's indeterminate<sup>p457</sup> IDL attribute is set to true, then the control's selection should be obscured as if the control was in a third, indeterminate, state.

**Note** *The control is never a true tri-state control, even if the element's indeterminate<sup>p457</sup> IDL attribute is set to true. The indeterminate<sup>p457</sup> IDL attribute only gives the appearance of a third state.*

If the element is mutable<sup>p527</sup>, then: The pre-click activation steps<sup>p725</sup> consist of setting the element's checkedness<sup>p527</sup> to its opposite value (i.e. true if it is false, false if it is true), and of setting the element's indeterminate<sup>p457</sup> IDL attribute to false. The anceled activation steps<sup>p725</sup> consist of setting the checkedness<sup>p527</sup> and the element's indeterminate<sup>p457</sup> IDL attribute back to the values they had before the pre-click activation steps<sup>p725</sup> were run. The activation behaviour<sup>p725</sup> is to fire a simple event<sup>p846</sup> that bubbles named input<sup>p494</sup> at the element and then fire a simple event<sup>p846</sup> that bubbles named change<sup>p494</sup> at the element.

If the element is not mutable<sup>p527</sup>, it has no activation behaviour<sup>p725</sup>.

**Constraint validation:** If the element is required<sup>p484</sup> and its checkedness<sup>p527</sup> is false, then the element is suffering from being missing<sup>p553</sup>.

**Note**

input.indeterminate<sup>p457</sup> [= value]

When set, overrides the rendering of checkbox<sup>p475</sup> controls so that the current value is not visible.

#### Bookkeeping details

- The following common input<sup>p452</sup> element content attributes and IDL attributes apply<sup>p455</sup> to the element: checked<sup>p457</sup>, and required<sup>p484</sup> content attributes; checked<sup>p492</sup> and value<sup>p492</sup> IDL attributes.
- The value<sup>p492</sup> IDL attribute is in mode default/on<sup>p492</sup>.
- The input<sup>p494</sup> and change<sup>p494</sup> events apply<sup>p455</sup>.
- The following content attributes must not be specified and do not apply<sup>p455</sup> to the element: accept<sup>p477</sup>, alt<sup>p480</sup>, autocomplete<sup>p535</sup>, dirname<sup>p529</sup>, formaction<sup>p531</sup>, formenctype<sup>p532</sup>, formmethod<sup>p531</sup>, formnovalidate<sup>p532</sup>, formtarget<sup>p532</sup>, height<sup>p397</sup>, inputmode<sup>p534</sup>, list<sup>p489</sup>, max<sup>p487</sup>, maxlength<sup>p483</sup>, min<sup>p487</sup>, minlength<sup>p483</sup>, multiple<sup>p485</sup>, pattern<sup>p486</sup>, placeholder<sup>p490</sup>, readonly<sup>p483</sup>, size<sup>p483</sup>, src<sup>p479</sup>, step<sup>p488</sup>, and width<sup>p397</sup>.
- The following IDL attributes and methods do not apply<sup>p455</sup> to the element: files<sup>p493</sup>, list<sup>p494</sup>, selectionStart<sup>p551</sup>, selectionEnd<sup>p551</sup>, selectionDirection<sup>p551</sup>, valueAsDate<sup>p493</sup>, valueAsNumber<sup>p493</sup>, valueLow<sup>p493</sup>, and valueHigh<sup>p493</sup> IDL attributes; select()<sup>p551</sup>, setRangeText()<sup>p551</sup>, setSelectionRange()<sup>p551</sup>, stepDown()<sup>p494</sup>, and stepUp()<sup>p494</sup> methods.

#### 4.10.5.1.17 Radio Button state (`type=radio`)

When an input<sup>p452</sup> element's type<sup>p454</sup> attribute is in the Radio Button<sup>p475</sup> state, the rules in this section apply.

The input<sup>p452</sup> element represents<sup>p111</sup> a control that, when used in conjunction with other input<sup>p452</sup> elements, forms a radio button group<sup>p475</sup> in which only one control can have its checkedness<sup>p527</sup> state set to true. If the element's checkedness<sup>p527</sup> state is true, the control represents the selected control in the group, and if it is false, it indicates a control in the group that is not selected.

The radio button group that contains an input<sup>p452</sup> element *a* also contains all the other input<sup>p452</sup> elements *b* that fulfill all of the following conditions:

- The input<sup>p452</sup> element *b*'s type<sup>p454</sup> attribute is in the Radio Button<sup>p475</sup> state.
- Either *a* and *b* have the same form owner<sup>p527</sup>, or they both have no form owner<sup>p527</sup>.
- Both *a* and *b* are in the same home subtree<sup>p42</sup>.

- They both have a `name`<sup>p529</sup> attribute, their `name`<sup>p529</sup> attributes are not empty, and the value of a's `name`<sup>p529</sup> attribute is a [compatibility caseless](#)<sup>b58</sup> match for the value of b's `name`<sup>p529</sup> attribute.

A document must not contain an `input`<sup>p452</sup> element whose [radio button group](#)<sup>p475</sup> contains only that element.

When any of the following phenomena occur, if the element's [checkedness](#)<sup>p527</sup> state is true after the occurrence, the [checkedness](#)<sup>p527</sup> state of all the other elements in the same [radio button group](#)<sup>p475</sup> must be set to false:

- The element's [checkedness](#)<sup>p527</sup> state is set to true (for whatever reason).
- The element's `name`<sup>p529</sup> attribute is set, changed, or removed.
- The element's [form owner](#)<sup>p527</sup> changes.
- [A type change is signalled](#)<sup>p457</sup> for the element.

If the element R is [mutable](#)<sup>p527</sup>, then: The [pre-click activation steps](#)<sup>p725</sup> for R consist of getting a reference to the element in R's [radio button group](#)<sup>p475</sup> that has its [checkedness](#)<sup>p527</sup> set to true, if any, and then setting R's [checkedness](#)<sup>p527</sup> to true. The [canceled activation steps](#)<sup>p725</sup> for R consist of checking if the element to which a reference was obtained in the [pre-click activation steps](#)<sup>p725</sup>, if any, is still in what is now R's [radio button group](#)<sup>p475</sup>, if it still has one, and if so, setting that element's [checkedness](#)<sup>p527</sup> to true; or else, if there was no such element, or that element is no longer in R's [radio button group](#)<sup>p475</sup>, or if R no longer has a [radio button group](#)<sup>p475</sup>, setting R's [checkedness](#)<sup>p527</sup> to false. The [activation behaviour](#)<sup>p725</sup> for R is to [fire a simple event](#)<sup>p846</sup> that bubbles named `input`<sup>p494</sup> at R and then [fire a simple event](#)<sup>p846</sup> that bubbles named `change`<sup>p494</sup> at R.

If the element is not [mutable](#)<sup>p527</sup>, it has no [activation behaviour](#)<sup>p725</sup>.

**Constraint validation:** If an element in the [radio button group](#)<sup>p475</sup> is [required](#)<sup>p484</sup>, and all of the `input`<sup>p452</sup> elements in the [radio button group](#)<sup>p475</sup> have a [checkedness](#)<sup>p527</sup> that is false, then the element is [suffering from being missing](#)<sup>p553</sup>.

**Note** *If none of the radio buttons in a [radio button group](#)<sup>p475</sup> are checked when they are inserted into the document, then they will all be initially unchecked in the interface, until such time as one of them is checked (either by the user or by script).*

#### Bookkeeping details

- The following common `input`<sup>p452</sup> element content attributes and IDL attributes [apply](#)<sup>p455</sup> to the element: `checked`<sup>p457</sup> and [required](#)<sup>p484</sup> content attributes; `checked`<sup>p492</sup> and `value`<sup>p492</sup> IDL attributes.
- The `value`<sup>p492</sup> IDL attribute is in mode [default/on](#)<sup>p492</sup>.
- The `input`<sup>p494</sup> and `change`<sup>p494</sup> events [apply](#)<sup>p455</sup>.
- The following content attributes must not be specified and [do not apply](#)<sup>p455</sup> to the element: `accept`<sup>p477</sup>, `alt`<sup>p480</sup>, `autocomplete`<sup>p535</sup>, `dirname`<sup>p529</sup>, `formaction`<sup>p531</sup>, `formenctype`<sup>p532</sup>, `formmethod`<sup>p531</sup>, `formnovalidate`<sup>p532</sup>, `formtarget`<sup>p532</sup>, `height`<sup>p397</sup>, `inputmode`<sup>p534</sup>, `list`<sup>p489</sup>, `max`<sup>p487</sup>, `maxlength`<sup>p483</sup>, `min`<sup>p487</sup>, `minlength`<sup>p483</sup>, `multiple`<sup>p485</sup>, `pattern`<sup>p486</sup>, `placeholder`<sup>p490</sup>, `readonly`<sup>p483</sup>, `size`<sup>p483</sup>, `src`<sup>p479</sup>, `step`<sup>p488</sup>, and `width`<sup>p397</sup>.
- The following IDL attributes and methods [do not apply](#)<sup>p455</sup> to the element: `files`<sup>b493</sup>, `list`<sup>p494</sup>, `selectionStart`<sup>p551</sup>, `selectionEnd`<sup>p551</sup>, `selectionDirection`<sup>p551</sup>, `valueAsDate`<sup>b493</sup>, `valueAsNumber`<sup>b493</sup>, `valueLow`<sup>p493</sup>, and `valueHigh`<sup>b493</sup> IDL attributes; `select()`<sup>p551</sup>, `setRangeText()`<sup>p551</sup>, `setSelectionRange()`<sup>p551</sup>, `stepDown()`<sup>p494</sup>, and `stepUp()`<sup>b494</sup> methods.

#### 4.10.5.1.18 File Upload state (`type=file`)

Spec bugs: 27333

When an `input`<sup>p452</sup> element's `type`<sup>p454</sup> attribute is in the [File Upload](#)<sup>p476</sup> state, the rules in this section apply.

The `input`<sup>p452</sup> element [represents](#)<sup>p111</sup> a list of **selected files**, each file consisting of a file name, a file type, and a file body (the contents of the file).

File names must not contain [path components](#)<sup>p476</sup>, even in the case that a user has selected an entire directory hierarchy or multiple files with the same name from different directories. **Path components**, for the purposes of the [File Upload](#)<sup>p476</sup> state, are those parts of file names that are separated by U+005C REVERSE SOLIDUS character (\) characters.

Unless the `multiple`<sup>p485</sup> attribute is set, there must be no more than one file in the list of [selected files](#)<sup>p476</sup>.

If the element is [mutable](#)<sup>p527</sup>, then the element's [activation behaviour](#)<sup>p725</sup> is to run the following steps:

1. If the algorithm is not [allowed to show a popup](#)<sup>p766</sup>, then abort these steps without doing anything else.
2. Return, but continue running these steps [in parallel](#)<sup>p41</sup>.

3. Optionally, wait until any prior execution of this algorithm has terminated.
4. Display a prompt to the user requesting that the user specify some files. If the [multiple](#)<sup>p485</sup> attribute is not set, there must be no more than one file selected; otherwise, any number may be selected. Files can be from the filesystem or created on the fly, e.g. a picture taken from a camera connected to the user's device.
5. Wait for the user to have made their selection.
6. [Queue a task](#)<sup>p835</sup> to first update the element's [selected files](#)<sup>p476</sup> so that it represents the user's selection, then [fire a simple event](#)<sup>p846</sup> that bubbles named [input](#)<sup>p494</sup> at the [input](#)<sup>p452</sup> element, and finally [fire a simple event](#)<sup>p846</sup> that bubbles named [change](#)<sup>p494</sup> at the [input](#)<sup>p452</sup> element.

If the element is [mutable](#)<sup>p527</sup>, the user agent should allow the user to change the files on the list in other ways also, e.g. adding or removing files by drag-and-drop. When the user does so, the user agent must [queue a task](#)<sup>p835</sup> to first update the element's [selected files](#)<sup>p476</sup> so that it represents the user's new selection, then [fire a simple event](#)<sup>p846</sup> that bubbles named [input](#)<sup>p494</sup> at the [input](#)<sup>p452</sup> element, and finally [fire a simple event](#)<sup>p846</sup> that bubbles named [change](#)<sup>p494</sup> at the [input](#)<sup>p452</sup> element.

If the element is not [mutable](#)<sup>p527</sup>, it has no [activation behaviour](#)<sup>p725</sup> and the user agent must not allow the user to change the element's selection.

**Constraint validation:** If the element is [required](#)<sup>p484</sup> and the list of [selected files](#)<sup>p476</sup> is empty, then the element is [suffering from being missing](#)<sup>p553</sup>.

The [accept](#) attribute may be specified to provide user agents with a hint of what file types will be accepted.

If specified, the attribute must consist of a [set of comma-separated tokens](#)<sup>b80</sup>, each of which must be an [ASCII case-insensitive](#)<sup>p58</sup> match for one of the following:

#### **The string "audio/\*"**

Indicates that sound files are accepted.

#### **The string "video/\*"**

Indicates that video files are accepted.

#### **The string "image/\*"**

Indicates that image files are accepted.

#### **A valid MIME type with no parameters**<sup>p42</sup>

Indicates that files of the specified type are accepted.

#### **A string whose first character is a U+002E FULL STOP character (.)**

Indicates that files with the specified file extension are accepted.

The tokens must not be [ASCII case-insensitive](#)<sup>p58</sup> matches for any of the other tokens (i.e. duplicates are not allowed). To obtain the list of tokens from the attribute, the user agent must [split the attribute value on commas](#)<sup>b81</sup>.

User agents may use the value of this attribute to display a more appropriate user interface than a generic file picker. For instance, given the value `image/*`, a user agent could offer the user the option of using a local camera or selecting a photograph from their photo collection; given the value `audio/*`, a user agent could offer the user the option of recording a clip using a headset microphone.

User agents should prevent the user from selecting files that are not accepted by one (or more) of these tokens.

**Note** *Authors are encouraged to specify both any MIME types and any corresponding extensions when looking for data in a specific format.*

#### **Example**

For example, consider an application that converts Microsoft Word documents to Open Document Format files. Since Microsoft Word documents are described with a wide variety of MIME types and extensions, the site can list several, as follows:

```
<input type="file" accept=".doc,.docx,.xml,application/msword,application/vnd.openxmlformats-officedocument.wordprocessingml.document">
```

On platforms that only use file extensions to describe file types, the extensions listed here can be used to filter the allowed documents, while the MIME types can be used with the system's type registration table (mapping MIME types to extensions used by the system), if any, to determine any other extensions to allow. Similarly, on a system that does not have file names or extensions but labels

documents with MIME types internally, the MIME types can be used to pick the allowed files, while the extensions can be used if the system has an extension registration table that maps known extensions to MIME types used by the system.

**⚠️Warning!** *Extensions tend to be ambiguous (e.g. there are an untold number of formats that use the ".dat" extension, and users can typically quite easily rename their files to have a ".doc" extension even if they are not Microsoft Word documents), and MIME types tend to be unreliable (e.g. many formats have no formally registered types, and many formats are in practice labeled using a number of different MIME types). Authors are reminded that, as usual, data received from a client should be treated with caution, as it may not be in an expected format even if the user is not hostile and the user agent fully obeyed the `accept`<sup>P477</sup> attribute's requirements.*

### Example

For historical reasons, the `value`<sup>P492</sup> IDL attribute prefixes the file name with the string "C:\fakepath\". Some legacy user agents actually included the full path (which was a security vulnerability). As a result of this, obtaining the file name from the `value`<sup>P492</sup> IDL attribute in a backwards-compatible way is non-trivial. The following function extracts the file name in a suitably compatible manner:

```
function extractFilename(path) {
 if (path.substr(0, 12) == "C:\\\\fakepath\\\\")
 return path.substr(12); // modern browser
 var x;
 x = path.lastIndexOf('/');
 if (x >= 0) // Unix-based path
 return path.substr(x+1);
 x = path.lastIndexOf('\\');
 if (x >= 0) // Windows-based path
 return path.substr(x+1);
 return path; // just the file name
}
```

This can be used as follows:

```
<p><input type="file" name="image" onchange="updateFilename(this.value)"></p>
<p>The name of the file you picked is: (none)</p>
<script>
 function updateFilename(path) {
 var name = extractFilename(path);
 document.getElementById('filename').textContent = name;
 }
</script>
```

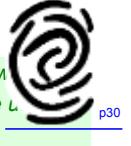

### Bookkeeping details

- The following common `input`<sup>P452</sup> element content attributes and IDL attributes `apply`<sup>P455</sup> to the element: `accept`<sup>P477</sup>, `multiple`<sup>P485</sup>, and `required`<sup>P484</sup> content attributes; `files`<sup>P493</sup> and `value`<sup>P492</sup> IDL attributes; `select()`<sup>P551</sup> method.
- The `value`<sup>P492</sup> IDL attribute is in mode `filename`<sup>P492</sup>.
- The `input`<sup>P494</sup> and `change`<sup>P494</sup> events `apply`<sup>P455</sup>.
- The following content attributes must not be specified and `do not apply`<sup>P455</sup> to the element: `alt`<sup>P480</sup>, `autocomplete`<sup>P535</sup>, `checked`<sup>P457</sup>, `dirname`<sup>P529</sup>, `formaction`<sup>P531</sup>, `formenctype`<sup>P532</sup>, `formmethod`<sup>P531</sup>, `formnovalidate`<sup>P532</sup>, `formtarget`<sup>P532</sup>, `height`<sup>P397</sup>, `inputmode`<sup>P534</sup>, `list`<sup>P489</sup>, `max`<sup>P487</sup>, `maxlength`<sup>P483</sup>, `min`<sup>P487</sup>, `minlength`<sup>P483</sup>, `pattern`<sup>P486</sup>, `placeholder`<sup>P490</sup>, `readonly`<sup>P483</sup>, `size`<sup>P483</sup>, `src`<sup>P479</sup>, `step`<sup>P488</sup>, and `width`<sup>P397</sup>.
- The element's `value`<sup>P457</sup> attribute must be omitted.
- The following IDL attributes and methods `do not apply`<sup>P455</sup> to the element: `checked`<sup>P492</sup>, `list`<sup>P494</sup>, `selectionStart`<sup>P551</sup>, `selectionEnd`<sup>P551</sup>, `selectionDirection`<sup>P551</sup>, `valueAsDate`<sup>P493</sup>, `valueAsNumber`<sup>P493</sup>, `valueLow`<sup>P493</sup>, and `valueHigh`<sup>P493</sup> IDL attributes; `setRangeText()`<sup>P551</sup>, `setSelectionRange()`<sup>P551</sup>, `stepDown()`<sup>P494</sup>, and `stepUp()`<sup>P494</sup> methods.

### 4.10.5.1.19 Submit Button state (`type=submit`)

When an `input`<sup>P452</sup> element's `type`<sup>P454</sup> attribute is in the `Submit Button`<sup>P478</sup> state, the rules in this section apply.

The `input`<sup>p452</sup> element `represents`<sup>p111</sup> a button that, when activated, submits the form. If the element has a `value`<sup>p457</sup> attribute, the button's label must be the value of that attribute; otherwise, it must be an implementation-defined string that means "Submit" or some such. The element is a `button`<sup>p447</sup>, specifically a `submit button`<sup>p447</sup>.

**Note** Since the default label is implementation-defined, and the width of the button typically depends on the button's label, the button's width may leak a few bits of fingerprintable information. These bits are likely to be strongly correlated to the identity of the user agent and the user's locale.

If the element is `mutable`<sup>p527</sup>, then the element's `activation behaviour`<sup>p725</sup> is as follows: if the element has a `form owner`<sup>p527</sup>, and the element's `node document` is `fully active`<sup>p763</sup>, `submit`<sup>p558</sup> the `form owner`<sup>p527</sup> from the `input`<sup>p452</sup> element; otherwise, do nothing.

If the element is not `mutable`<sup>p527</sup>, it has no `activation behaviour`<sup>p725</sup>.

The `formaction`<sup>p531</sup>, `formenctype`<sup>p532</sup>, `formmethod`<sup>p531</sup>, `formnovalidate`<sup>p532</sup>, and `formtarget`<sup>p532</sup> attributes are [attributes for form submission](#)<sup>p531</sup>.

**Note** The `formnovalidate`<sup>p532</sup> attribute can be used to make submit buttons that do not trigger the constraint validation.

#### Bookkeeping details

- The following common `input`<sup>p452</sup> element content attributes and IDL attributes `apply`<sup>p455</sup> to the element: `formaction`<sup>p531</sup>, `formenctype`<sup>p532</sup>, `formmethod`<sup>p531</sup>, `formnovalidate`<sup>p532</sup>, and `formtarget`<sup>p532</sup> content attributes; `value`<sup>p492</sup> IDL attribute.
- The `value`<sup>p492</sup> IDL attribute is in mode `default`<sup>p492</sup>.
- The following content attributes must not be specified and `do not apply`<sup>p455</sup> to the element: `accept`<sup>p477</sup>, `alt`<sup>p480</sup>, `autocomplete`<sup>p535</sup>, `checked`<sup>p457</sup>, `dirname`<sup>p529</sup>, `height`<sup>p397</sup>, `inputmode`<sup>p324</sup>, `list`<sup>p489</sup>, `max`<sup>p487</sup>, `maxlength`<sup>p483</sup>, `min`<sup>p487</sup>,  `minlength`<sup>p483</sup>, `multiple`<sup>p485</sup>, `pattern`<sup>p486</sup>, `placeholder`<sup>p490</sup>, `readonly`<sup>p483</sup>, `required`<sup>p484</sup>, `size`<sup>p483</sup>, `src`<sup>p479</sup>, `step`<sup>p488</sup>, and `width`<sup>p397</sup>.
- The following IDL attributes and methods `do not apply`<sup>p455</sup> to the element: `checked`<sup>p492</sup>, `files`<sup>p493</sup>, `list`<sup>p494</sup>, `selectionStart`<sup>p551</sup>, `selectionEnd`<sup>p551</sup>, `selectionDirection`<sup>p551</sup>, `valueAsDate`<sup>p493</sup>, `valueAsNumber`<sup>p493</sup>, `valueLow`<sup>p493</sup>, and `valueHigh`<sup>p493</sup> IDL attributes; `select()`<sup>p551</sup>, `setRangeText()`<sup>p551</sup>, `setSelectionRange()`<sup>p551</sup>, `stepDown()`<sup>p494</sup>, and `stepUp()`<sup>p494</sup> methods.
- The `input`<sup>p494</sup> and `change`<sup>p494</sup> events `do not apply`<sup>p455</sup>.

#### 4.10.5.1.20 Image Button state (`type=image`)

When an `input`<sup>p452</sup> element's `type`<sup>p454</sup> attribute is in the `Image Button`<sup>p479</sup> state, the rules in this section apply.

The `input`<sup>p452</sup> element `represents`<sup>p111</sup> either an image from which a user can select a coordinate and submit the form, or alternatively a button from which the user can submit the form. The element is a `button`<sup>p447</sup>, specifically a `submit button`<sup>p447</sup>.

**Note** The coordinate is sent to the server during form submission<sup>p561</sup> by sending two entries for the element, derived from the name of the control but with ".x" and ".y" appended to the name with the x and y components of the coordinate respectively.

The image is given by the `src` attribute. The `src`<sup>p479</sup> attribute must be present, and must contain a valid non-empty URL potentially surrounded by spaces<sup>p82</sup> referencing a non-interactive, optionally animated, image resource that is neither paged nor scripted.

When any of the following events occur, unless the user agent cannot support images, or its support for images has been disabled, or the user agent only fetches elements on demand, or the `src`<sup>p479</sup> attribute's value is the empty string, the user agent must `resolve`<sup>p82</sup> the value of the `src`<sup>p479</sup> attribute, relative to the element, and if that is successful, must `fetch`<sup>p84</sup> the resulting `absolute URL`<sup>p48</sup>:

- The `input`<sup>p452</sup> element's `type`<sup>p454</sup> attribute is first set to the `Image Button`<sup>p479</sup> state (possibly when the element is first created), and the `src`<sup>p479</sup> attribute is present.
- The `input`<sup>p452</sup> element's `type`<sup>p454</sup> attribute is changed back to the `Image Button`<sup>p479</sup> state, and the `src`<sup>p479</sup> attribute is present, and its value has changed since the last time the `type`<sup>p454</sup> attribute was in the `Image Button`<sup>p479</sup> state.
- The `input`<sup>p452</sup> element's `type`<sup>p454</sup> attribute is in the `Image Button`<sup>p479</sup> state, and the `src`<sup>p479</sup> attribute is set or changed.

Fetching the image must `delay the load event`<sup>p1033</sup> of the element's `node document` until the `task`<sup>p834</sup> that is `queued`<sup>p835</sup> by the `networking task source`<sup>p839</sup> once the resource has been `fetched`<sup>p84</sup> (defined below) has been run.

If the image was successfully obtained, with no network errors, and the image's type is a supported image type, and the image is a valid image of that type, then the image is said to be **available**. If this is true before the image is completely downloaded, each [task<sup>p834</sup>](#) that is [queued<sup>p835</sup>](#) by the [networking task source<sup>p839</sup>](#) while the image is being [fetched<sup>p84</sup>](#) must update the presentation of the image appropriately.

The user agent should apply the [image sniffing rules](#) to determine the type of the image, with the image's [associated Content-Type headers<sup>p86</sup>](#) giving the [official type](#). If these rules are not applied, then the type of the image must be the type given by the image's [associated Content-Type headers<sup>p86</sup>](#).

User agents must not support non-image resources with the [input<sup>p452</sup>](#) element. User agents must not run executable code embedded in the image resource. User agents must only display the first page of a multipage resource. User agents must not allow the resource to act in an interactive fashion, but should honor any animation in the resource.

The [task<sup>p834</sup>](#) that is [queued<sup>p835</sup>](#) by the [networking task source<sup>p839</sup>](#) once the resource has been [fetched<sup>p84</sup>](#), must, if the download was successful and the image is [available<sup>p480</sup>](#), [queue a task<sup>p835</sup>](#) to [fire a simple event<sup>p846</sup>](#) named [load<sup>b1144</sup>](#) at the [input<sup>p452</sup>](#) element; and otherwise, if the fetching process fails without a response from the remote server, or completes but the image is not a valid or supported image, [queue a task<sup>p835</sup>](#) to [fire a simple event<sup>p846</sup>](#) named [error<sup>p1144</sup>](#) on the [input<sup>p452</sup>](#) element.

The [alt](#) attribute provides the textual label for the button for users and user agents who cannot use the image. The [alt<sup>p480</sup>](#) attribute must be present, and must contain a non-empty string giving the label that would be appropriate for an equivalent button if the image was unavailable.

The [input<sup>p452</sup>](#) element supports [dimension attributes<sup>p397</sup>](#).

If the [src<sup>b479</sup>](#) attribute is set, and the image is [available<sup>p480</sup>](#) and the user agent is configured to display that image, then: The element [represents<sup>p111</sup>](#) a control for selecting a [coordinate<sup>p480</sup>](#) from the image specified by the [src<sup>p479</sup>](#) attribute; if the element is [mutable<sup>p527</sup>](#), the user agent should allow the user to select this [coordinate<sup>p480</sup>](#), and the element's [activation behaviour<sup>p725</sup>](#) is as follows: if the element has a [form owner<sup>p527</sup>](#), and the element's [node document](#) is [fully active<sup>p763</sup>](#), take the user's selected [coordinate<sup>p480</sup>](#), and [submit<sup>p558</sup>](#) the [input<sup>p452</sup>](#) element's [form owner<sup>p527</sup>](#) from the [input<sup>p452</sup>](#) element. If the user activates the control without explicitly selecting a coordinate, then the coordinate (0,0) must be assumed.

Otherwise, the element [represents<sup>p111</sup>](#) a submit button whose label is given by the value of the [alt<sup>p480</sup>](#) attribute; if the element is [mutable<sup>p527</sup>](#), then the element's [activation behaviour<sup>p725</sup>](#) is as follows: if the element has a [form owner<sup>p527</sup>](#), and the element's [node document](#) is [fully active<sup>p763</sup>](#), set the [selected coordinate<sup>p480</sup>](#) to (0,0), and [submit<sup>p558</sup>](#) the [input<sup>p452</sup>](#) element's [form owner<sup>p527</sup>](#) from the [input<sup>p452</sup>](#) element.

In either case, if the element is [mutable<sup>p527</sup>](#) but has no [form owner<sup>p527</sup>](#) or the element's [node document](#) is not [fully active<sup>p763</sup>](#), then its [activation behaviour<sup>p725</sup>](#) must be to do nothing. If the element is not [mutable<sup>p527</sup>](#), it has no [activation behaviour<sup>p725</sup>](#).

The **selected coordinate** must consist of an x-component and a y-component. The coordinates represent the position relative to the edge of the image, with the coordinate space having the positive x direction to the right, and the positive y direction downwards.

The x-component must be a [valid integer<sup>p60</sup>](#) representing a number  $x$  in the range  $-(borderleft+paddingleft) \leq x \leq width+borderright+paddingright$ , where *width* is the rendered width of the image, *borderleft* is the width of the border on the left of the image, *paddingleft* is the width of the padding on the left of the image, *borderright* is the width of the border on the right of the image, and *paddingright* is the width of the padding on the right of the image, with all dimensions given in CSS pixels.

The y-component must be a [valid integer<sup>p60</sup>](#) representing a number  $y$  in the range  $-(bordertop+paddingtop) \leq y \leq height+borderbottom+paddingbottom$ , where *height* is the rendered height of the image, *bordertop* is the width of the border above the image, *paddingtop* is the width of the padding above the image, *borderbottom* is the width of the border below the image, and *paddingbottom* is the width of the padding below the image, with all dimensions given in CSS pixels.

Where a border or padding is missing, its width is zero CSS pixels.

The [formaction<sup>p531</sup>](#), [formenctype<sup>p532</sup>](#), [formmethod<sup>p531</sup>](#), [formnovalidate<sup>p532</sup>](#), and [formtarget<sup>p532</sup>](#) attributes are [attributes for form submission<sup>p531</sup>](#).

Note

`image.widthp458 [= value]`

`image.heightp458 [= value]`

These attributes return the actual rendered dimensions of the image, or zero if the dimensions are not known.

They can be set, to change the corresponding content attributes.

#### Bookkeeping details

- The following common `inputp452` element content attributes and IDL attributes `applyp455` to the element: `altp480`, `formactionp531`, `formenctypep532`, `formmethodp531`, `formnovalidatep532`, `formtargetb532`, `heightb397`, `srcp479`, and `widthp397` content attributes; `valuep492` IDL attribute.
- The `valuep492` IDL attribute is in mode `defaultp492`.
- The following content attributes must not be specified and `do not applyp455` to the element: `acceptp477`, `autocompletep535`, `checkedp457`, `dirnamep529`, `inputmodep534`, `listp489`, `maxp487`, `maxlengthp483`, `minp487`,  `minlengthp483`, `multiplep485`, `patternb486`, `placeholderp490`, `readonlyp483`, `requiredp484`, `sizep483`, and `stepb488`.
- The element's `valuep457` attribute must be omitted.
- The following IDL attributes and methods `do not applyp455` to the element: `checkedp492`, `filesp493`, `listp494`, `selectionStartp551`, `selectionEndp551`, `selectionDirectionp551`, `valueAsDatep493`, `valueAsNumberp493`, `valueLowp493`, and `valueHighp493` IDL attributes; `select()p551`, `setRangeText()p551`, `setSelectionRange()p551`, `stepDown()p494`, and `stepUp()p494` methods.
- The `inputp494` and `changeb494` events `do not applyp455`.

**Note** Many aspects of this state's behaviour are similar to the behaviour of the `imgp272` element. Readers are encouraged to read that section, where many of the same requirements are described in more detail.

#### Example

Take the following form:

```
<form action="process.cgi">
 <input type=image src=map.png name=where alt="Show location list">
</form>
```

If the user clicked on the image at coordinate (127,40) then the URL used to submit the form would be "process.cgi?where.x=127&where.y=40".

(In this example, it's assumed that for users who don't see the map, and who instead just see a button labeled "Show location list", clicking the button will cause the server to show a list of locations to pick from instead of the map.)

#### 4.10.5.1.21 Reset Button state (`type=reset`)

When an `inputp452` element's `typep454` attribute is in the `Reset Buttonp481` state, the rules in this section apply.

The `inputp452` element `representsb111` a button that, when activated, resets the form. If the element has a `valuep457` attribute, the button's label must be the value of that attribute; otherwise, it must be an implementation-defined string that means "Reset" or some such. The element is a `buttonp447`.

**Note** Since the default label is implementation-defined, and the width of the button typically depends on the button's label, the button's width may leak a few bits of fingerprintable information. These bits are likely to be strongly correlated to the identity of the user agent and the user's locale.

If the element is `mutablep527`, then the element's `activation behaviourp725`, if the element has a `form ownerp527` and the element's `node document` is `fully activep763`, is to `resetp567` the `form ownerp527`; otherwise, it is to do nothing.

If the element is not `mutablep527`, it has no `activation behaviourp725`.

**Constraint validation:** The element is `barred from constraint validationp553`.

#### Bookkeeping details

- The `valuep492` IDL attribute `appliesp455` to this element and is in mode `defaultp492`.

- The following content attributes must not be specified and do not apply<sup>p455</sup> to the element: accept<sup>p477</sup>, alt<sup>p480</sup>, autocomplete<sup>p535</sup>, checked<sup>p457</sup>, dirname<sup>p529</sup>, formaction<sup>p531</sup>, formenctype<sup>p532</sup>, formmethod<sup>p531</sup>, formnovalidate<sup>p532</sup>, formtarget<sup>p532</sup>, height<sup>p397</sup>, inputmode<sup>p534</sup>, list<sup>p489</sup>, max<sup>p487</sup>, maxlength<sup>p483</sup>, min<sup>p487</sup>,  minlength<sup>p483</sup>, multiple<sup>p485</sup>, pattern<sup>p486</sup>, placeholder<sup>p490</sup>, readonly<sup>p483</sup>, required<sup>p484</sup>, size<sup>p483</sup>, src<sup>p479</sup>, step<sup>p488</sup>, and width<sup>p397</sup>.
- The following IDL attributes and methods do not apply<sup>p455</sup> to the element: checked<sup>p492</sup>, files<sup>p493</sup>, list<sup>p494</sup>, selectionStart<sup>p551</sup>, selectionEnd<sup>p551</sup>, selectionDirection<sup>p551</sup>, valueAsDate<sup>p493</sup>, valueAsNumber<sup>p493</sup>, valueLow<sup>p493</sup>, and valueHigh<sup>p493</sup> IDL attributes; select()<sup>p551</sup>, setRangeText()<sup>p551</sup>, setSelectionRange()<sup>p551</sup>, stepDown()<sup>p494</sup>, and stepUp()<sup>p494</sup> methods.
- The input<sup>p494</sup> and change<sup>p494</sup> events do not apply<sup>p455</sup>.

#### 4.10.5.1.22 Button state (*type=button*)

When an input<sup>p452</sup> element's type<sup>p454</sup> attribute is in the Button<sup>p482</sup> state, the rules in this section apply.

The input<sup>p452</sup> element represents<sup>p111</sup> a button with no default behaviour. A label for the button must be provided in the value<sup>p457</sup> attribute, though it may be the empty string. If the element has a value<sup>p457</sup> attribute, the button's label must be the value of that attribute; otherwise, it must be the empty string. The element is a button<sup>p447</sup>.

If the element is mutable<sup>p527</sup>, the element's activation behaviour<sup>p725</sup> is to do nothing.

If the element is not mutable<sup>p527</sup>, it has no activation behaviour<sup>p725</sup>.

**Constraint validation:** The element is barred from constraint validation<sup>p553</sup>.

##### Bookkeeping details

- The value<sup>p492</sup> IDL attribute applies<sup>p455</sup> to this element and is in mode default<sup>p482</sup>.
- The following content attributes must not be specified and do not apply<sup>p455</sup> to the element: accept<sup>p477</sup>, alt<sup>p480</sup>, autocomplete<sup>p535</sup>, checked<sup>p457</sup>, dirname<sup>p529</sup>, formaction<sup>p531</sup>, formenctype<sup>p532</sup>, formmethod<sup>p531</sup>, formnovalidate<sup>p532</sup>, formtarget<sup>p532</sup>, height<sup>p397</sup>, inputmode<sup>p534</sup>, list<sup>p489</sup>, max<sup>p487</sup>, maxlength<sup>p483</sup>, min<sup>p487</sup>,  minlength<sup>p483</sup>, multiple<sup>p485</sup>, pattern<sup>p486</sup>, placeholder<sup>p490</sup>, readonly<sup>p483</sup>, required<sup>p484</sup>, size<sup>p483</sup>, src<sup>p479</sup>, step<sup>p488</sup>, and width<sup>p397</sup>.
- The following IDL attributes and methods do not apply<sup>p455</sup> to the element: checked<sup>p492</sup>, files<sup>p493</sup>, list<sup>p494</sup>, selectionStart<sup>p551</sup>, selectionEnd<sup>p551</sup>, selectionDirection<sup>p551</sup>, valueAsDate<sup>p493</sup>, valueAsNumber<sup>p493</sup>, valueLow<sup>p493</sup>, and valueHigh<sup>p493</sup> IDL attributes; select()<sup>p551</sup>, setRangeText()<sup>p551</sup>, setSelectionRange()<sup>p551</sup>, stepDown()<sup>p494</sup>, and stepUp()<sup>p494</sup> methods.
- The input<sup>p494</sup> and change<sup>p494</sup> events do not apply<sup>p455</sup>.

#### 4.10.5.2 Implementation notes regarding localization of form controls

*This section is non-normative.*

The formats shown to the user in date, time, and number controls is independent of the format used for form submission.

Browsers are encouraged to use user interfaces that present dates, times, and numbers according to the conventions of either the locale implied by the input<sup>p452</sup> element's language<sup>p123</sup> or the user's preferred locale. Using the page's locale will ensure consistency with page-provided data.

**Example** For example, it would be confusing to users if an American English page claimed that a Cirque De Soleil show was going to be showing on 02/03, but their browser, configured to use the British English locale, only showed the date 03/02 in the ticket purchase date picker. Using the page's locale would at least ensure that the date was presented in the same format everywhere. (There's still a risk that the user would end up arriving a month late, of course, but there's only so much that can be done about such cultural differences...)

#### 4.10.5.3 Common input<sup>p452</sup> element attributes

These attributes only apply<sup>p455</sup> to an input<sup>p452</sup> element if its type<sup>p454</sup> attribute is in a state whose definition declares that the attribute applies<sup>p455</sup>. When an attribute doesn't apply<sup>p455</sup> to an input<sup>p452</sup> element, user agents must ignore<sup>p42</sup> the attribute, regardless of the requirements and definitions below.

#### 4.10.5.3.1 The `maxlength`<sup>p483</sup> and `minlength`<sup>p483</sup> attributes

The `maxlength` attribute, when it applies<sup>p455</sup>, is a [form control `maxlength` attribute](#)<sup>p529</sup> controlled by the `input`<sup>p452</sup> element's [dirty value flag](#)<sup>p456</sup>.

The `minlength` attribute, when it applies<sup>p455</sup>, is a [form control `minlength` attribute](#)<sup>p530</sup> controlled by the `input`<sup>p452</sup> element's [dirty value flag](#)<sup>p456</sup>.

If the `input`<sup>p452</sup> element has a [maximum allowed value length](#)<sup>p529</sup>, then the [code-unit length](#)<sup>p44</sup> of the value of the element's `value`<sup>p457</sup> attribute must be equal to or less than the element's [maximum allowed value length](#)<sup>p529</sup>.

##### Example

The following extract shows how a messaging client's text entry could be arbitrarily restricted to a fixed number of characters, thus forcing any conversation through this medium to be terse and discouraging intelligent discourse.

```
<label>What are you doing? <input name=status maxlength=140></label>
```

##### Example

Here, a password is given a minimum length:

```
<p><label>Username: <input name=u required></label>
<p><label>Password: <input name=p required minlength=12></label>
```

#### 4.10.5.3.2 The `size`<sup>p483</sup> attribute

The `size` attribute gives the number of characters that, in a visual rendering, the user agent is to allow the user to see while editing the element's `value`<sup>p527</sup>.

The `size`<sup>p483</sup> attribute, if specified, must have a value that is a [valid non-negative integer](#)<sup>p61</sup> greater than zero.

If the attribute is present, then its value must be parsed using the [rules for parsing non-negative integers](#)<sup>p61</sup>, and if the result is a number greater than zero, then the user agent should ensure that at least that many characters are visible.

The `size`<sup>p458</sup> IDL attribute is [limited to only non-negative numbers greater than zero](#)<sup>p89</sup> and has a default value of 20.

#### 4.10.5.3.3 The `readonly`<sup>p483</sup> attribute

The `readonly` attribute is a [boolean attribute](#)<sup>p59</sup> that controls whether or not the user can edit the form control. When specified, the element is not [mutable](#)<sup>p527</sup>.

**Constraint validation:** If the `readonly`<sup>p483</sup> attribute is specified on an `input`<sup>p452</sup> element, the element is [barred from constraint validation](#)<sup>p553</sup>.

**Note** *The difference between `disabled`<sup>p530</sup> and `readonly`<sup>p483</sup> is that read-only controls are still focusable, so the user can still select the text and interact with it, whereas disabled controls are entirely non-interactive. (For this reason, only text controls can be made read-only: it wouldn't make sense for checkboxes or buttons, for instances.)*

##### Example

In the following example, the existing product identifiers cannot be modified, but they are still displayed as part of the form, for consistency with the row representing a new product (where the identifier is not yet filled in).

```
<form action="products.cgi" method="post" enctype="multipart/form-data">
 <table>
 <tr> <th> Product ID <th> Product name <th> Price <th> Action
 <tr>
 <td> <input readonly="readonly" name="1.pid" value="H412">
 <td> <input required="required" name="1.pname" value="Floor lamp Ulke">
 <td> $<input required="required" type="number" min="0" step="0.01" name="1.pprice"
 value="49.99">
 <td> <button formnovalidate="formnovalidate" name="action" value="delete:1">Delete</button>
 <tr>
 <td> <input readonly="readonly" name="2.pid" value="FG28">
```

```

<td> <input required="required" name="2.pname" value="Table lamp Ulke">
<td> $<input required="required" type="number" min="0" step="0.01" name="2.pprice"
value="24.99">
<td> <button formnovalidate="formnovalidate" name="action" value="delete:2">Delete</button>
<tr>
<td> <input required="required" name="3.pid" value="" pattern="[A-Z0-9]+">
<td> <input required="required" name="3.pname" value="">
<td> $<input required="required" type="number" min="0" step="0.01" name="3.pprice" value="">
<td> <button formnovalidate="formnovalidate" name="action" value="delete:3">Delete</button>
</table>
<p> <button formnovalidate="formnovalidate" name="action" value="add">Add</button> </p>
<p> <button name="action" value="update">Save</button> </p>
</form>

```

#### 4.10.5.3.4 The **required**<sup>p484</sup> attribute

The **required** attribute is a boolean attribute<sup>p59</sup>. When specified, the element is **required**.

**Constraint validation:** If the element is **required**<sup>p484</sup>, and its value<sup>p492</sup> IDL attribute applies<sup>p455</sup> and is in the mode value<sup>p492</sup>, and the element is mutable<sup>p527</sup>, and the element's value<sup>p527</sup> is the empty string, then the element is suffering from being missing<sup>p553</sup>.

##### Example

The following form has two required fields, one for an e-mail address and one for a password. It also has a third field that is only considered valid if the user types the same password in the password field and this third field.

```

<h1>Create new account</h1>
<form action="/newaccount" method=post
 oninput="up2.setCustomValidity(up2.value != up.value ? 'Passwords do not match.' : '')">
<p>
 <label for="username">E-mail address:</label>
 <input id="username" type=email required name=un>
<p>
 <label for="password1">Password:</label>
 <input id="password1" type=password required name=up>
<p>
 <label for="password2">Confirm password:</label>
 <input id="password2" type=password name=up2>
<p>
 <input type=submit value="Create account">
</form>

```

##### Example

For radio buttons, the **required**<sup>p484</sup> attribute is satisfied if any of the radio buttons in the group<sup>p475</sup> is selected. Thus, in the following example, any of the radio buttons can be checked, not just the one marked as required:

```

<fieldset>
<legend>Did the movie pass the Bechdel test?</legend>
<p><label><input type="radio" name="bechdel" value="no-characters"> No, there are not even two
female characters in the movie. </label>
<p><label><input type="radio" name="bechdel" value="no-names"> No, the female characters never
talk to each other. </label>
<p><label><input type="radio" name="bechdel" value="no-topic"> No, when female characters talk
to each other it's always about a male character. </label>
<p><label><input type="radio" name="bechdel" value="yes" required> Yes. </label>
<p><label><input type="radio" name="bechdel" value="unknown"> I don't know. </label>
</fieldset>

```

To avoid confusion as to whether a radio button group<sup>p475</sup> is required or not, authors are encouraged to specify the attribute on all the radio buttons in a group. Indeed, in general, authors are encouraged to avoid having radio button groups that do not have any initially

checked controls in the first place, as this is a state that the user cannot return to, and is therefore generally considered a poor user interface.

#### 4.10.5.3.5 The multiple<sup>p485</sup> attribute

The **multiple** attribute is a [boolean attribute](#)<sup>p59</sup> that indicates whether the user is to be allowed to specify more than one value.

##### Example

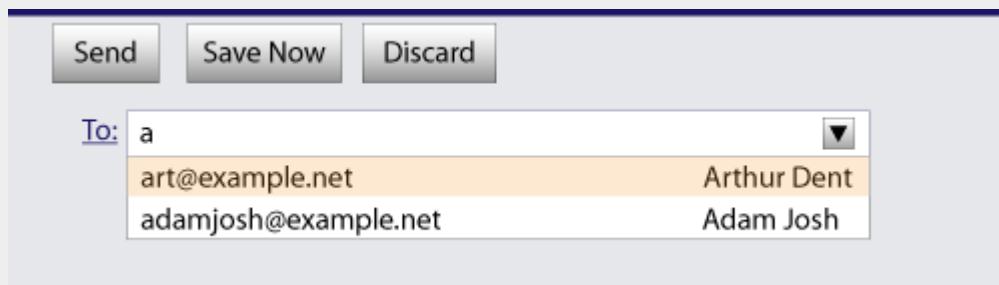

The following extract shows how an e-mail client's "Cc" field could accept multiple e-mail addresses.

```
<label>Cc: <input type=email multiple name=cc></label>
```

If the user had, amongst many friends in his user contacts database, two friends "Arthur Dent" (with address "art@example.net") and "Adam Josh" (with address "adamjosh@example.net"), then, after the user has typed "a", the user agent might suggest addresses to the user.

Support:	
Chrome	5+
IE	10+
Chrome for Android	None
Firefox	3.6+
iOS Safari	6.0-6.1+
Android Browser	None
UC Browser for Android	None
Opera Mini	4+
Opera	10.6+
IE Mobile	None
Firefox for Android	None

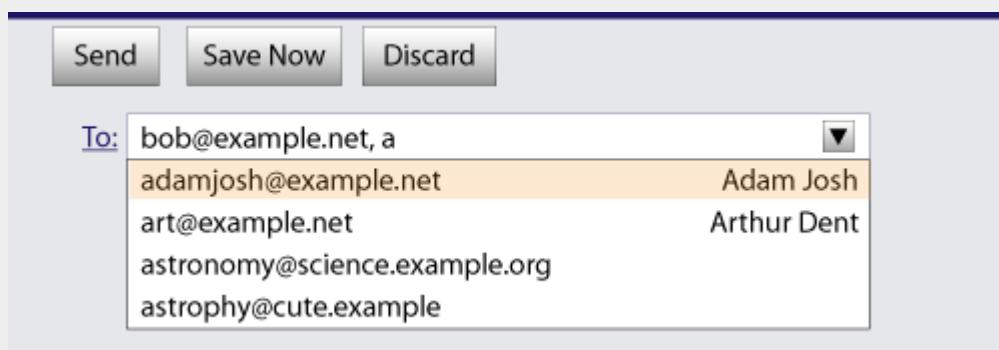

Source: [caniuse.com](#)

The page could also link in the user's contacts database from the site:

```
<label>Cc: <input type=email multiple name=cc list=contacts></label>
...
<datalist id="contacts">
<option value="hederal@damowmow.com">
<option value="pillar@example.com">
<option value="astrophysics@cute.example">
<option value="astronomy@science.example.org">
</datalist>
```

Suppose the user had entered "bob@example.net" into this text field, and then started typing a second e-mail address starting with "a". The user agent might show both the two friends mentioned earlier, as well as the "astrophysics" and "astronomy" values given in the [datalist](#)<sup>p503</sup> element.

##### Example

The following extract shows how an e-mail client's "Attachments" field could accept multiple files for upload.

```
<label>Attachments: <input type=file multiple name=att></label>
```

#### 4.10.5.3.6 The pattern<sup>p486</sup> attribute

The pattern attribute specifies a regular expression against which the control's value<sup>p527</sup>, or, when the multiple<sup>p485</sup> attribute is set, the control's values<sup>p527</sup>, are to be checked.

If specified, the attribute's value must match the JavaScript *Pattern* production. [ECMA262]<sup>p1150</sup>

If an input<sup>p452</sup> element has a pattern<sup>p486</sup> attribute specified, and the attribute's value, when compiled as a JavaScript regular expression, only the "u" flag specified, compiles successfully, then the resulting regular expression is the element's **compiled pattern regular expression**. If the element has no such attribute, or if the value doesn't compile successfully, then the element has no compiled pattern regular expression. [ECMA262]<sup>p1150</sup>

Support:	
Chrome	10+
IE	10+
Chrome for Android	40+
Firefox	4+
iOS Safari	None
Android Browser	4.4.3-4.4.4+
UC Browser for Android	9.9+

Safari	None
Opera	9.5-9.6+
IE Mobile (limited)	10+
Firefox for Android	33+

Source: caniuse.com

**Constraint validation:** If the element's value<sup>p527</sup> is not the empty string, and either the element's multiple<sup>p485</sup> attribute is not specified or it does not apply<sup>p455</sup> to the input<sup>p452</sup> element given its type<sup>p454</sup> attribute's current state, and the element has a compiled pattern regular expression<sup>p486</sup> but that regular expression does not match the entirety of the element's value<sup>p527</sup>, then the element is suffering from a pattern mismatch<sup>p553</sup>.

**Constraint validation:** If the element's value<sup>p527</sup> is not the empty string, and the element's multiple<sup>p485</sup> attribute is specified and applies<sup>p455</sup> to the input<sup>p452</sup> element, and the element has a compiled pattern regular expression<sup>p486</sup> but that regular expression does not match the entirety of each of the element's values<sup>p527</sup>, then the element is suffering from a pattern mismatch<sup>p553</sup>.

The compiled pattern regular expression<sup>p486</sup>, when matched against a string, must have its start anchored to the start of the string and its end anchored to the end of the string.

**Note** This implies that the regular expression language used for this attribute is the same as that used in JavaScript, except that the pattern<sup>p486</sup> attribute is matched against the entire value, not just any subset (somewhat as if it implied a `^ (? : at the start of the pattern and a ) $ at the end`).

When an input<sup>p452</sup> element has a pattern<sup>p486</sup> attribute specified, authors should include a title attribute to give a description of the pattern. User agents may use the contents of this attribute, if it is present, when informing the user that the pattern is not matched, or at any other suitable time, such as in a tooltip or read out by assistive technology when the control gains focus<sup>p728</sup>.

##### Example

For example, the following snippet:

```
<label> Part number:
<input pattern="[0-9][A-Z]{3}" name="part"
 title="A part number is a digit followed by three uppercase letters." />
</label>
```

...could cause the UA to display an alert such as:

```
A part number is a digit followed by three uppercase letters.
You cannot submit this form when the field is incorrect.
```

When a control has a pattern<sup>p486</sup> attribute, the title<sup>p486</sup> attribute, if used, must describe the pattern. Additional information could also be included, so long as it assists the user in filling in the control. Otherwise, assistive technology would be impaired.

**Example** For instance, if the title attribute contained the caption of the control, assistive technology could end up saying something like The text you have entered does not match the required pattern. Birthday, which is not useful.

UAs may still show the title<sup>p122</sup> in non-error situations (for example, as a tooltip when hovering over the control), so authors should be careful not to word title<sup>p486</sup>s as if an error has necessarily occurred.

#### 4.10.5.3.7 The min<sup>p487</sup> and max<sup>p487</sup> attributes

Some form controls can have explicit constraints applied limiting the allowed range of values that the user can provide. Normally, such a range would be linear and continuous. A form control can **have a periodic domain**, however, in which case the form control's broadest possible range is finite, and authors can specify explicit ranges within it that span the boundaries.

**Example** Specifically, the broadest range of a `type=time`<sup>p467</sup> control is midnight to midnight (24 hours), and authors can set both continuous linear ranges (such as 9pm to 11pm) and discontinuous ranges spanning midnight (such as 11pm to 1am).

The `min` and `max` attributes indicate the allowed range of values for the element.

Their syntax is defined by the section that defines the `type`<sup>p454</sup> attribute's current state.

If the element has a `min`<sup>p487</sup> attribute, and the result of applying the [algorithm to convert a string to a number](#)<sup>p456</sup> to the value of the `min`<sup>p487</sup> attribute is a number, then that number is the element's **minimum**; otherwise, if the `type`<sup>p454</sup> attribute's current state defines a **default minimum**, then that is the `minimum`<sup>p487</sup>; otherwise, the element has no `minimum`<sup>p487</sup>.

The `min`<sup>p487</sup> attribute also defines the `step base`<sup>p488</sup>.

If the element has a `max`<sup>p487</sup> attribute, and the result of applying the [algorithm to convert a string to a number](#)<sup>p456</sup> to the value of the `max`<sup>p487</sup> attribute is a number, then that number is the element's **maximum**; otherwise, if the `type`<sup>p454</sup> attribute's current state defines a **default maximum**, then that is the `maximum`<sup>p487</sup>; otherwise, the element has no `maximum`<sup>p487</sup>.

If the element does not [have a periodic domain](#)<sup>p486</sup>, the `max`<sup>p487</sup> attribute's value (the `maximum`<sup>p487</sup>) must not be less than the `min`<sup>p487</sup> attribute's value (its `minimum`<sup>p487</sup>).

**Note** If an element that does not [have a periodic domain](#)<sup>p486</sup> has a `maximum`<sup>p487</sup> that is less than its `minimum`<sup>p487</sup>, then so long as the element has a `value`<sup>p527</sup>, it will either be [suffering from an underflow](#)<sup>p553</sup> or [suffering from an overflow](#)<sup>p553</sup>.

An element **has a reversed range** if it [has a periodic domain](#)<sup>p486</sup> and its `maximum`<sup>p487</sup> is less than its `minimum`<sup>p487</sup>.

An element **has range limitations** if it has a defined `minimum`<sup>p487</sup> or a defined `maximum`<sup>p487</sup>.

How these range limitations apply depends on whether the element has a `multiple`<sup>p485</sup> attribute.

↪ If the element does not have a `multiple`<sup>p485</sup> attribute specified or if the `multiple`<sup>p485</sup> attribute does not apply<sup>p455</sup>

**Constraint validation:** When the element has a `minimum`<sup>p487</sup> and does not [have a reversed range](#)<sup>p487</sup>, and the result of applying the [algorithm to convert a string to a number](#)<sup>p456</sup> to the string given by the element's `value`<sup>p527</sup> is a number, and the number obtained from that algorithm is less than the `minimum`<sup>p487</sup>, the element is [suffering from an underflow](#)<sup>p553</sup>.

**Constraint validation:** When the element has a `maximum`<sup>p487</sup> and does not [have a reversed range](#)<sup>p487</sup>, and the result of applying the [algorithm to convert a string to a number](#)<sup>p456</sup> to the string given by the element's `value`<sup>p527</sup> is a number, and the number obtained from that algorithm is more than the `maximum`<sup>p487</sup>, the element is [suffering from an overflow](#)<sup>p553</sup>.

**Constraint validation:** When an element [has a reversed range](#)<sup>p487</sup>, and the result of applying the [algorithm to convert a string to a number](#)<sup>p456</sup> to the string given by the element's `value`<sup>p527</sup> is a number, and the number obtained from that algorithm is more than the `maximum`<sup>p487</sup> and less than the `minimum`<sup>p487</sup>, the element is simultaneously [suffering from an underflow](#)<sup>p553</sup> and [suffering from an overflow](#)<sup>p553</sup>.

↪ If the element does have a `multiple`<sup>p485</sup> attribute specified and the `multiple`<sup>p485</sup> attribute does apply<sup>p455</sup>

**Constraint validation:** When the element has a `minimum`<sup>p487</sup>, and the result of applying the [algorithm to convert a string to a number](#)<sup>p456</sup> to any of the strings in the element's `values`<sup>p527</sup> is a number that is less than the `minimum`<sup>p487</sup>, the element is [suffering from an underflow](#)<sup>p553</sup>.

**Constraint validation:** When the element has a `maximum`<sup>p487</sup>, and the result of applying the [algorithm to convert a string to a number](#)<sup>p456</sup> to any of the strings in the element's `values`<sup>p527</sup> is a number that is more than the `maximum`<sup>p487</sup>, the element is [suffering from an overflow](#)<sup>p553</sup>.

**Example**

The following date control limits input to dates that are before the 1980s:

```
<input name=bdy type=date max="1979-12-31">
```

**Example**

The following number control limits input to whole numbers greater than zero:

```
<input name=quantity required="" type="number" min="1" value="1">
```

**Example**

The following time control limits input to those minutes that occur between 9pm and 6am, defaulting to midnight:

```
<input name="sleepStart" type="time" min="21:00" max="06:00" step="60" value="00:00">
```

#### 4.10.5.3.8 The step<sup>p488</sup> attribute

The step attribute indicates the granularity that is expected (and required) of the value<sup>p527</sup> or values<sup>p527</sup>, by limiting the allowed values. The section that defines the type<sup>p454</sup> attribute's current state also defines the **default step**, the **step scale factor**, and in some cases the **default step base**, which are used in processing the attribute as described below.

The step<sup>p488</sup> attribute, if specified, must either have a value that is a valid floating-point number<sup>p61</sup> that parses<sup>p62</sup> to a number that is greater than zero, or must have a value that is an ASCII case-insensitive<sup>p58</sup> match for the string "any".

The attribute provides the **allowed value step** for the element, as follows:

1. If the attribute is absent, then the allowed value step<sup>p488</sup> is the default step<sup>p488</sup> multiplied by the step scale factor<sup>p488</sup>.
2. Otherwise, if the attribute's value is an ASCII case-insensitive<sup>p58</sup> match for the string "any", then there is no allowed value step<sup>p488</sup>.
3. Otherwise, if the rules for parsing floating-point number values<sup>p62</sup>, when they are applied to the attribute's value, return an error, zero, or a number less than zero, then the allowed value step<sup>p488</sup> is the default step<sup>p488</sup> multiplied by the step scale factor<sup>p488</sup>.
4. Otherwise, the allowed value step<sup>p488</sup> is the number returned by the rules for parsing floating-point number values<sup>p62</sup> when they are applied to the attribute's value, multiplied by the step scale factor<sup>p488</sup>.

The **step base** is the value returned by the following algorithm:

1. If the element has a min<sup>p487</sup> content attribute, and the result of applying the algorithm to convert a string to a number<sup>p456</sup> to the value of the min<sup>p487</sup> content attribute is not an error, then return that result and abort these steps.
2. If the element does not have a multiple<sup>p485</sup> attribute specified or if the multiple<sup>p485</sup> attribute does not apply<sup>p455</sup>, then: if the element has a value<sup>p457</sup> content attribute, and the result of applying the algorithm to convert a string to a number<sup>p456</sup> to the value of the value<sup>p457</sup> content attribute is not an error, then return that result and abort these steps.

Otherwise, the element's type<sup>p454</sup> attribute is in the Range<sup>p470</sup> state and the element has a multiple<sup>p485</sup> attribute specified: run these substeps:

1. If the element does not have a value<sup>p457</sup> content attribute, skip these substeps.
  2. Split on commas<sup>p81</sup> the value of the value<sup>p457</sup> content attribute.
  3. If the result of the previous step was not exactly two values, or if either gets an error when you apply the algorithm to convert a string to a number<sup>p456</sup>, then skip these substeps.
  4. Return the lower of the two numbers obtained in the previous step, and abort these steps.
3. If a default step base<sup>p488</sup> is defined for this element given its type<sup>p454</sup> attribute's state, then return it and abort these steps.
  4. Return zero.

How these range limitations apply depends on whether the element has a multiple<sup>p485</sup> attribute.

↪ If the element does not have a multiple<sup>p485</sup> attribute specified or if the multiple<sup>p485</sup> attribute does not apply<sup>p455</sup>

**Constraint validation:** When the element has an allowed value step<sup>p488</sup>, and the result of applying the algorithm to convert a string to a number<sup>p456</sup> to the string given by the element's value<sup>p527</sup> is a number, and that number subtracted from the step base<sup>p488</sup> is not an integral multiple of the allowed value step<sup>p488</sup>, the element is suffering from a step mismatch<sup>p553</sup>.

↪ If the element does have a multiple<sup>p485</sup> attribute specified and the multiple<sup>p485</sup> attribute does apply<sup>p455</sup>

**Constraint validation:** When the element has an allowed value step<sup>p488</sup>, and the result of applying the algorithm to convert a string to a number<sup>p456</sup> to any of the strings in the element's values<sup>p527</sup> is a number that, when subtracted from the step base<sup>p488</sup>, is not an integral multiple of the allowed value step<sup>p488</sup>, the element is suffering from a step mismatch<sup>p553</sup>.

Example

The following range control only accepts values in the range 0..1, and allows 256 steps in that range:

```
<input name=opacity type=range min=0 max=1 step=0.00392156863>
```

#### Example

The following control allows any time in the day to be selected, with any accuracy (e.g. thousandth-of-a-second accuracy or more):

```
<input name=favtime type=time step=any>
```

Normally, time controls are limited to an accuracy of one minute.

#### 4.10.5.3.9 The list<sup>p489</sup> attribute

The list attribute is used to identify an element that lists predefined options suggested to the user.

If present, its value must be the ID<sup>p51</sup> of a datalist<sup>p503</sup> element in the same document.

The **suggestions source element** is the first element in the document in tree order<sup>p42</sup> to have an ID<sup>p51</sup> equal to the value of the list<sup>p489</sup> attribute, if that element is a datalist<sup>p503</sup> element. If there is no list<sup>p489</sup> attribute, or if there is no element with that ID<sup>p51</sup>, or if the first element with that ID<sup>p51</sup> is not a datalist<sup>p503</sup> element, then there is no suggestions source element<sup>p489</sup>.

If there is a suggestions source element<sup>p489</sup>, then, when the user agent is allowing the user to edit the input<sup>p452</sup> element's value<sup>p527</sup>, the user agent should offer the suggestions represented by the suggestions source element<sup>p489</sup> to the user in a manner suitable for the type of control used. The user agent may use the suggestion's label<sup>p506</sup> to identify the suggestion if appropriate.

User agents are encouraged to filter the suggestions represented by the suggestions source element<sup>p489</sup> when the number of suggestions is large, including only the most relevant ones (e.g. based on the user's input so far). No precise threshold is defined, but capping the list at four to seven values is reasonable.

How user selections of suggestions are handled depends on whether the element is a control accepting a single value only, or whether it accepts multiple values:

- ↪ If the element does not have a multiple<sup>p485</sup> attribute specified or if the multiple<sup>p485</sup> attribute does not apply<sup>p455</sup>

When the user selects a suggestion, the input<sup>p452</sup> element's value<sup>p527</sup> must be set to the selected suggestion's value<sup>p506</sup>, as if the user had written that value himself.

- ↪ If the element's type<sup>p454</sup> attribute is in the Range<sup>p470</sup> state and the element has a multiple<sup>p485</sup> attribute specified

When the user selects a suggestion, the user agent must identify which value in the element's values<sup>p527</sup> the user intended to update, and must then update the element's values<sup>p527</sup> so that the relevant value is changed to the value given by the selected suggestion's value<sup>p506</sup>, as if the user had himself set it to that value.

- ↪ If the element's type<sup>p454</sup> attribute is in the Email<sup>p461</sup> state and the element has a multiple<sup>p485</sup> attribute specified

When the user selects a suggestion, the user agent must either add a new entry to the input<sup>p452</sup> element's values<sup>p527</sup>, whose value is the selected suggestion's value<sup>p506</sup>, or change an existing entry in the input<sup>p452</sup> element's values<sup>p527</sup> to have the value given by the selected suggestion's value<sup>p506</sup>, as if the user had himself added an entry with that value, or edited an existing entry to be that value. Which behaviour is to be applied depends on the user interface in a user-agent-defined manner.

If the list<sup>p489</sup> attribute does not apply<sup>p455</sup>, there is no suggestions source element<sup>p489</sup>.

#### Example

This URL field offers some suggestions.

```
<label>Homepage: <input name=hp type=url list=hpurls></label>
<datalist id=hpurls>
 <option value="http://www.google.com/" label="Google">
 <option value="http://www.reddit.com/" label="Reddit">
</datalist>
```

Other URLs from the user's history might show also; this is up to the user agent.

#### Example

This example demonstrates how to design a form that uses the autocomplete list feature while still degrading usefully in legacy user agents.

If the autocomplete list is merely an aid, and is not important to the content, then simply using a `datalist`<sup>p503</sup> element with children `option`<sup>p505</sup> elements is enough. To prevent the values from being rendered in legacy user agents, they need to be placed inside the `value`<sup>p506</sup> attribute instead of inline.

```
<p>
 <label>
 Enter a breed:
 <input type="text" name="breed" list="breeds">
 <datalist id="breeds">
 <option value="Abyssinian">
 <option value="Alpaca">
 <!-- ... -->
 </datalist>
 </label>
</p>
```

However, if the values need to be shown in legacy UAs, then fallback content can be placed inside the `datalist`<sup>p503</sup> element, as follows:

```
<p>
 <label>
 Enter a breed:
 <input type="text" name="breed" list="breeds">
 </label>
 <datalist id="breeds">
 <label>
 or select one from the list:
 <select name="breed">
 <option value=""> (none selected)
 <option>Abyssinian
 <option>Alpaca
 <!-- ... -->
 </select>
 </label>
 </datalist>
</p>
```

The fallback content will only be shown in UAs that don't support `datalist`<sup>p503</sup>. The options, on the other hand, will be detected by all UAs, even though they are not children of the `datalist`<sup>p503</sup> element.

Note that if an `option`<sup>p505</sup> element used in a `datalist`<sup>p503</sup> is `selected`<sup>p506</sup>, it will be selected by default by legacy UAs (because it affects the `select`<sup>p498</sup>), but it will not have any effect on the `input`<sup>p452</sup> element in UAs that support `datalist`<sup>p503</sup>.

#### 4.10.5.3.10 The `placeholder`<sup>p490</sup> attribute

Spec bugs: [19899](#)

The `placeholder` attribute represents a *short* hint (a word or short phrase) intended to aid the user with data entry when the control has no value. A hint could be a sample value or a brief description of the expected format. The attribute, if specified, must have a value that contains no U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters.

The `placeholder`<sup>p490</sup> attribute should not be used as an alternative to a `label`<sup>p451</sup>. For a longer hint or other advisory text, the `title`<sup>p122</sup> attribute is more appropriate.

**Note** These mechanisms are very similar but subtly different: the hint given by the control's `label`<sup>p451</sup> is shown at all times; the hint in the `placeholder`<sup>p490</sup> attribute is shown before the user enters a value; and the hint in the `title`<sup>p122</sup> attribute is shown when the user requests further help.

Support:	
Chrome	4+
IE	10+
Chrome for Android	40+
Firefox	4+
iOS Safari	3.2+
Android Browser	4.2.4.3+
UC Browser for Android	9.9+
Opera Mini	None
Safari	5+
Opera	11.5+
IE Mobile	10+
Firefox for Android	33+

Source: [caniuse.com](#)

User agents should present this hint to the user, after having stripped line breaks<sup>p59</sup> from it, when the element's value<sup>p527</sup> is the empty string, especially if the control is not focused<sup>p728</sup>.

If a user agent normally doesn't show this hint to the user when the control is focused<sup>p728</sup>, then the user agent should nonetheless show the hint for the control if it was focused as a result of the autofocus<sup>b533</sup> attribute, since in that case the user will not have had an opportunity to examine the control before focusing it.

#### Example

Here is an example of a mail configuration user interface that uses the placeholder<sup>p490</sup> attribute:

```
<fieldset>
 <legend>Mail Account</legend>
 <p><label>Name: <input type="text" name="fullname" placeholder="John Ratzenberger"></label></p>
 <p><label>Address: <input type="email" name="address" placeholder="john@example.net"></label></p>
 <p><label>Password: <input type="password" name="password"></label></p>
 <p><label>Description: <input type="text" name="desc" placeholder="My Email Account"></label></p>
</fieldset>
```

#### Example

In situations where the control's content has one directionality but the placeholder needs to have a different directionality, Unicode's bidirectional-algorithm formatting characters can be used in the attribute value:

```
<input name=t1 type=tel placeholder="‫ رقم الهاتف 1 ‮">
<input name=t2 type=tel placeholder="‫ 2 رقم الهاتف ‮">
```

For slightly more clarity, here's the same example using numeric character references instead of inline Arabic:

```
<input name=t1 type=tel
placeholder="‫رقم الهاتف 1‮">
<input name=t2 type=tel
placeholder="‫رقم الهاتف 2‮">
```

#### 4.10.5.4 Common `input`<sup>p452</sup> element APIs

##### Note

###### `input.value`<sup>p492</sup> [= value]

Returns the current value<sup>p527</sup> of the form control.

Can be set, to change the value.

Throws an `InvalidStateError`<sup>p50</sup> exception if it is set to any value other than the empty string when the control is a file upload control.

###### `input.checked`<sup>p492</sup> [= value]

Returns the current checkedness<sup>p527</sup> of the form control.

Can be set, to change the checkedness<sup>p527</sup>.

###### `input.files`<sup>p493</sup>

Returns a `FileList`<sup>p52</sup> object listing the selected files<sup>p476</sup> of the form control.

Returns null if the control isn't a file control.

###### `input.valueAsDate`<sup>p493</sup> [= value]

Returns a `Date`<sup>p49</sup> object representing the form control's value<sup>p527</sup>, if applicable; otherwise, returns null.

Can be set, to change the value.

Throws an `InvalidStateError`<sup>p50</sup> exception if the control isn't date- or time-based.

### `input.valueAsNumberp493 [= value]`

Returns a number representing the form control's [value<sup>p527</sup>](#), if applicable; otherwise, returns NaN.

Can be set, to change the value. Setting this to NaN will set the underlying value to the empty string.

Throws an [InvalidStateError<sup>p50</sup>](#) exception if the control is neither date- or time-based nor numeric.

### `input.valueLowp493 [= value]`

### `input.valueHighp493 [= value]`

Returns a number representing the low and high components of form control's [value<sup>p527</sup>](#) respectively, if applicable; otherwise, returns NaN.

Can be set, to change the value.

Throws an [InvalidStateError<sup>p50</sup>](#) exception if the control is not a two-handle range control.

### `input.stepUpp494([ n ])`

### `input.stepDownp494([ n ])`

Changes the form control's [value<sup>p527</sup>](#) by the value given in the [step<sup>p488</sup>](#) attribute, multiplied by *n*. The default value for *n* is 1.

Throws [InvalidStateError<sup>p50</sup>](#) exception if the control is neither date- or time-based nor numeric, or if the [step<sup>p488</sup>](#) attribute's value is "any".

### `input.listp494`

Returns the [datalist<sup>p503</sup>](#) element indicated by the [list<sup>p489</sup>](#) attribute.

The **value** IDL attribute allows scripts to manipulate the [value<sup>p527</sup>](#) of an [input<sup>p452</sup>](#) element. The attribute is in one of the following modes, which define its behaviour:

#### **value**

On getting, it must return the current [value<sup>p527</sup>](#) of the element. On setting, it must set the element's [value<sup>p527</sup>](#) to the new value, set the element's [dirty value flag<sup>p456</sup>](#) to true, invoke the [value sanitization algorithm<sup>p456</sup>](#), if the element's [type<sup>p454</sup>](#) attribute's current state defines one, and then, if the element has a text entry cursor position, should move the text entry cursor position to the end of the text field, unselecting any selected text and resetting the selection direction to *none*.

#### **default**

On getting, if the element has a [value<sup>p457</sup>](#) attribute, it must return that attribute's value; otherwise, it must return the empty string. On setting, it must set the element's [value<sup>p457</sup>](#) attribute to the new value.

#### **default/on**

On getting, if the element has a [value<sup>p457</sup>](#) attribute, it must return that attribute's value; otherwise, it must return the string "on". On setting, it must set the element's [value<sup>p457</sup>](#) attribute to the new value.

#### **filename**

On getting, it must return the string "C:\fakepath\" followed by the name of the first file in the list of [selected files<sup>p476</sup>](#), if any, or the empty string if the list is empty. On setting, if the new value is the empty string, it must empty the list of [selected files<sup>p476</sup>](#); otherwise, it must throw an [InvalidStateError<sup>p50</sup>](#) exception.

**Note** This "fakepath" requirement is a sad accident of history. See [the example in the File Upload state section<sup>p478</sup>](#) for more information.

**Note** Since [path components<sup>p476</sup>](#) are not permitted in file names in the list of [selected files<sup>p476</sup>](#), the "fakepath\" cannot be mistaken for a path component.

The **checked** IDL attribute allows scripts to manipulate the [checkedness<sup>p527</sup>](#) of an [input<sup>p452</sup>](#) element. On getting, it must return the current [checkedness<sup>p527</sup>](#) of the element; and on setting, it must set the element's [checkedness<sup>p527</sup>](#) to the new value and set the element's [dirty checkedness flag<sup>p457</sup>](#) to true.

The `files` IDL attribute allows scripts to access the element's [selected files](#)<sup>p476</sup>. On getting, if the IDL attribute [applies](#)<sup>p455</sup>, it must return a [FileList](#)<sup>p52</sup> object that represents the current [selected files](#)<sup>p476</sup>. The same object must be returned until the list of [selected files](#)<sup>p476</sup> changes. If the IDL attribute [does not apply](#)<sup>p455</sup>, then it must instead return null. [\[FILEAPI\]](#)<sup>p1150</sup>

The `valueAsDate` IDL attribute represents the [value](#)<sup>p527</sup> of the element, interpreted as a date.

On getting, if the [valueAsDate](#)<sup>p493</sup> attribute [does not apply](#)<sup>p455</sup>, as defined for the [input](#)<sup>p452</sup> element's [type](#)<sup>p454</sup> attribute's current state, then return null. Otherwise, run the [algorithm to convert a string to a Date object](#)<sup>p456</sup> defined for that state to the element's [value](#)<sup>p527</sup>; if the algorithm returned a [Date](#)<sup>p49</sup> object, then return it, otherwise, return null.

On setting, if the [valueAsDate](#)<sup>p493</sup> attribute [does not apply](#)<sup>p455</sup>, as defined for the [input](#)<sup>p452</sup> element's [type](#)<sup>p454</sup> attribute's current state, then throw an [InvalidStateError](#)<sup>p50</sup> exception; otherwise, if the new value is null or a [Date](#)<sup>p49</sup> object representing the NaN time value, then set the [value](#)<sup>p527</sup> of the element to the empty string; otherwise, run the [algorithm to convert a Date object to a string](#)<sup>p456</sup>, as defined for that state, on the new value, and set the [value](#)<sup>p527</sup> of the element to the resulting string.

The `valueAsNumber` IDL attribute represents the [value](#)<sup>p527</sup> of the element, interpreted as a number.

On getting, if the [valueAsNumber](#)<sup>p493</sup> attribute [does not apply](#)<sup>p455</sup>, as defined for the [input](#)<sup>p452</sup> element's [type](#)<sup>p454</sup> attribute's current state, then return a Not-a-Number (NaN) value. Otherwise, if the [valueAsDate](#)<sup>p493</sup> attribute [applies](#)<sup>p455</sup>, run the [algorithm to convert a string to a Date object](#)<sup>p456</sup> defined for that state to the element's [value](#)<sup>p527</sup>; if the algorithm returned a [Date](#)<sup>p49</sup> object, then return the *time value* of the object (the number of milliseconds from midnight UTC the morning of 1970-01-01 to the time represented by the [Date](#)<sup>p49</sup> object), otherwise, return a Not-a-Number (NaN) value. Otherwise, run the [algorithm to convert a string to a number](#)<sup>p456</sup> defined for that state to the element's [value](#)<sup>p527</sup>; if the algorithm returned a number, then return it, otherwise, return a Not-a-Number (NaN) value.

On setting, if the new value is infinite, then throw a [TypeError](#)<sup>p50</sup> exception. Otherwise, if the [valueAsNumber](#)<sup>p493</sup> attribute [does not apply](#)<sup>p455</sup>, as defined for the [input](#)<sup>p452</sup> element's [type](#)<sup>p454</sup> attribute's current state, then throw an [InvalidStateError](#)<sup>p50</sup> exception. Otherwise, if the new value is a Not-a-Number (NaN) value, then set the [value](#)<sup>p527</sup> of the element to the empty string. Otherwise, if the [valueAsDate](#)<sup>p493</sup> attribute [applies](#)<sup>p455</sup>, run the [algorithm to convert a Date object to a string](#)<sup>p456</sup> defined for that state, passing it a [Date](#)<sup>p49</sup> object whose *time value* is the new value, and set the [value](#)<sup>p527</sup> of the element to the resulting string. Otherwise, run the [algorithm to convert a number to a string](#)<sup>p456</sup>, as defined for that state, on the new value, and set the [value](#)<sup>p527</sup> of the element to the resulting string.

The `valueLow` and `valueHigh` IDL attributes represent the [value](#)<sup>p527</sup> of the element, interpreted as a comma-separated pair of numbers.

On getting, if the attributes [do not apply](#)<sup>p455</sup>, as defined for the [input](#)<sup>p452</sup> element's [type](#)<sup>p454</sup> attribute's current state, then return zero; otherwise, run the following steps:

1. Let *values* be the [values](#)<sup>p527</sup> of the element, interpreted according to the [algorithm to convert a string to a number](#)<sup>p456</sup>, as defined by the [input](#)<sup>p452</sup> element's [type](#)<sup>p454</sup> attribute's current state.
2. If the attribute in question is [valueLow](#)<sup>p493</sup>, return the lowest of the values in *values*; otherwise, return the highest of the values in *values*.

On setting, if the attributes [do not apply](#)<sup>p455</sup>, as defined for the [input](#)<sup>p452</sup> element's [type](#)<sup>p454</sup> attribute's current state, then throw an [InvalidStateError](#)<sup>b50</sup> exception. Otherwise, run the following steps:

1. Let *values* be the [values](#)<sup>p527</sup> of the element, interpreted according to the [algorithm to convert a string to a number](#)<sup>p456</sup>, as defined by the [input](#)<sup>p452</sup> element's [type](#)<sup>p454</sup> attribute's current state.
2. Let *new value* be the result of running the [algorithm to convert a number to a string](#)<sup>p456</sup>, as defined for that state, on the new value.
3. If the attribute in question is [valueLow](#)<sup>p493</sup>, replace the lower value in *values* with *new value*; otherwise, replace the higher value in *values* with *new value*.
4. Sort *values* in increasing numeric order.
5. Let *values*<sup>b527</sup> be the result of running the [algorithm to convert a number to a string](#)<sup>p456</sup>, as defined by the [input](#)<sup>p452</sup> element's [type](#)<sup>p454</sup> attribute's current state, to the values in *values*.

- Set the element's `value`<sup>p527</sup> to the concatenation of the strings in `values`<sup>p527</sup>, separating each value from the next by a U+002C COMMA character (,).

The `stepDown (n)` and `stepUp (n)` methods, when invoked, must run the following algorithm:

- If the `stepDown ()`<sup>p494</sup> and `stepUp ()`<sup>p494</sup> methods do not apply<sup>p455</sup>, as defined for the `input`<sup>p452</sup> element's `type`<sup>p454</sup> attribute's current state, then throw an `InvalidStateError`<sup>p50</sup> exception, and abort these steps.
- If the element has no allowed value step<sup>p488</sup>, then throw an `InvalidStateError`<sup>p50</sup> exception, and abort these steps.
- If the element has a `minimum`<sup>p487</sup> and a `maximum`<sup>p487</sup> and the `minimum`<sup>p487</sup> is greater than the `maximum`<sup>p487</sup>, then abort these steps.
- If the element has a `minimum`<sup>p487</sup> and a `maximum`<sup>p487</sup> and there is no value greater than or equal to the element's `minimum`<sup>p487</sup> and less than or equal to the element's `maximum`<sup>p487</sup> that, when subtracted from the `step base`<sup>p488</sup>, is an integral multiple of the allowed value step<sup>p488</sup>, then abort these steps.
- If applying the algorithm to convert a string to a number<sup>p456</sup> to the string given by the element's `value`<sup>p527</sup> does not result in an error, then let `value` be the result of that algorithm. Otherwise, let `value` be zero.
- If `value` subtracted from the `step base`<sup>p488</sup> is not an integral multiple of the allowed value step<sup>p488</sup>, then set `value` to the nearest value that, when subtracted from the `step base`<sup>p488</sup>, is an integral multiple of the allowed value step<sup>p488</sup>, and that is less than `value` if the method invoked was the `stepDown ()`<sup>p494</sup> and more than `value` otherwise.

Otherwise (`value` subtracted from the `step base`<sup>p488</sup> is an integral multiple of the allowed value step<sup>p488</sup>), run the following substeps:

- Let `n` be the argument.
- Let `delta` be the allowed value step<sup>p488</sup> multiplied by `n`.
- If the method invoked was the `stepDown ()`<sup>p494</sup> method, negate `delta`.
- Let `value` be the result of adding `delta` to `value`.
- If the element has a `minimum`<sup>p487</sup>, and `value` is less than that `minimum`<sup>p487</sup>, then set `value` to the smallest value that, when subtracted from the `step base`<sup>p488</sup>, is an integral multiple of the allowed value step<sup>p488</sup>, and that is more than or equal to `minimum`.
- If the element has a `maximum`<sup>p487</sup>, and `value` is greater than that `maximum`<sup>p487</sup>, then set `value` to the largest value that, when subtracted from the `step base`<sup>p488</sup>, is an integral multiple of the allowed value step<sup>p488</sup>, and that is less than or equal to `maximum`.
- Let `value as string` be the result of running the algorithm to convert a number to a string<sup>p456</sup>, as defined for the `input`<sup>p452</sup> element's `type`<sup>p454</sup> attribute's current state, on `value`.
- Set the `value`<sup>p527</sup> of the element to `value as string`.

The `list` IDL attribute must return the current suggestions source element<sup>p489</sup>, if any, or null otherwise.

#### 4.10.5.5 Common event behaviours

When the `input`<sup>p494</sup> and `change`<sup>p494</sup> events apply<sup>p455</sup> (which is the case for all `input`<sup>p452</sup> controls other than `buttons`<sup>p447</sup> and those with the `type`<sup>p454</sup> attribute in the `Hidden`<sup>p488</sup> state), the events are fired to indicate that the user has interacted with the control. The `input` event fires whenever the user has modified the data of the control. The `change` event fires when the value is committed, if that makes sense for the control, or else when the control loses focus<sup>p733</sup>. In all cases, the `input`<sup>p494</sup> event comes before the corresponding `change`<sup>p494</sup> event (if any).

When an `input`<sup>p452</sup> element has a defined activation behaviour<sup>p725</sup>, the rules for dispatching these events, if they apply<sup>p455</sup>, are given in the section above that defines the `type`<sup>p454</sup> attribute's state. (This is the case for all `input`<sup>p452</sup> controls with the `type`<sup>p454</sup> attribute in the `Checkbox`<sup>p475</sup> state, the `Radio Button`<sup>p475</sup> state, or the `File Upload`<sup>p476</sup> state.)

For `input`<sup>p452</sup> elements without a defined activation behaviour<sup>p725</sup>, but to which these events apply<sup>p455</sup>, and for which the user interface involves both interactive manipulation and an explicit commit action, then when the user changes the element's `value`<sup>p527</sup>, the user agent must queue a

[task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> that bubbles named [input](#)<sup>p494</sup> at the [input](#)<sup>p452</sup> element, and any time the user commits the change, the user agent must [queue a task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> that bubbles named [change](#)<sup>p494</sup> at the [input](#)<sup>p452</sup> element.

**Example** An example of a user interface involving both interactive manipulation and a commit action would be a [Range](#)<sup>p470</sup> controls that use a slider, when manipulated using a pointing device. While the user is dragging the control's knob, [input](#)<sup>p494</sup> events would fire whenever the position changed, whereas the [change](#)<sup>p494</sup> event would only fire when the user let go of the knob, committing to a specific value.

For [input](#)<sup>p452</sup> elements without a defined [activation behaviour](#)<sup>p725</sup>, but to which these events [apply](#)<sup>p455</sup>, and for which the user interface involves an explicit commit action but no intermediate manipulation, then any time the user commits a change to the element's [value](#)<sup>p527</sup>, the user agent must [queue a task](#)<sup>p835</sup> to first [fire a simple event](#)<sup>p846</sup> that bubbles named [input](#)<sup>p494</sup> at the [input](#)<sup>p452</sup> element, and then [fire a simple event](#)<sup>p846</sup> that bubbles named [change](#)<sup>p494</sup> at the [input](#)<sup>p452</sup> element.

**Example** An example of a user interface with a commit action would be a [Colour](#)<sup>p474</sup> control that consists of a single button that brings up a colour wheel: if the [value](#)<sup>p527</sup> only changes when the dialog is closed, then that would be the explicit commit action. On the other hand, if manipulating the control changes the colour interactively, then there might be no commit action.

**Example** Another example of a user interface with a commit action would be a [Date](#)<sup>p464</sup> control that allows both text-based user input and user selection from a drop-down calendar: while text input might not have an explicit commit step, selecting a date from the drop down calendar and then dismissing the drop down would be a commit action.

For [input](#)<sup>p452</sup> elements without a defined [activation behaviour](#)<sup>p725</sup>, but to which these events [apply](#)<sup>p455</sup>, any time the user causes the element's [value](#)<sup>p527</sup> to change without an explicit commit action, the user agent must [queue a task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> that bubbles named [input](#)<sup>p494</sup> at the [input](#)<sup>p452</sup> element. The corresponding [change](#)<sup>p494</sup> event, if any, will be fired when the control [loses focus](#)<sup>p733</sup>.

**Example** Examples of a user changing the element's [value](#)<sup>p527</sup> would include the user typing into a text field, pasting a new value into the field, or undoing an edit in that field. Some user interactions do not cause changes to the value, e.g. hitting the "delete" key in an empty text field, or replacing some text in the field with text from the clipboard that happens to be exactly the same text.

**Example** A [Range](#)<sup>p470</sup> control in the form of a slider that the user has [focused](#)<sup>p728</sup> and is interacting with using a keyboard would be another example of the user changing the element's [value](#)<sup>p527</sup> without a commit step.

In the case of [tasks](#)<sup>p834</sup> that just fire an [input](#)<sup>p494</sup> event, user agents may wait for a suitable break in the user's interaction before [queuing](#)<sup>p835</sup> the tasks; for example, a user agent could wait for the user to have not hit a key for 100ms, so as to only fire the event when the user pauses, instead of continuously for each keystroke.

When the user agent is to change an [input](#)<sup>p452</sup> element's [value](#)<sup>p527</sup> on behalf of the user (e.g. as part of a form prefilling feature), the user agent must [queue a task](#)<sup>p835</sup> to first update the [value](#)<sup>p527</sup> accordingly, then [fire a simple event](#)<sup>p846</sup> that bubbles named [input](#)<sup>p494</sup> at the [input](#)<sup>p452</sup> element, then [fire a simple event](#)<sup>p846</sup> that bubbles named [change](#)<sup>p494</sup> at the [input](#)<sup>p452</sup> element.

**Note** *These events are not fired in response to changes made to the values of form controls by scripts. (This is to make it easier to update the values of form controls in response to the user manipulating the controls, without having to then filter out the script's own changes to avoid an infinite loop.)*

The [task source](#)<sup>p835</sup> for these [tasks](#)<sup>p834</sup> is the [user interaction task source](#)<sup>p838</sup>.

#### 4.10.6 The [button](#) element

**Categories**<sup>p113</sup>:

[Flow content](#)<sup>p115</sup>.  
[Phrasing content](#)<sup>p116</sup>.  
[Interactive content](#)<sup>p116</sup>.  
[Listed](#)<sup>p446</sup>, [labelable](#)<sup>p447</sup>, [submittable](#)<sup>p447</sup>, and [reassociateable](#)<sup>p447</sup> [form-associated element](#)<sup>p446</sup>.  
[Palpable content](#)<sup>p117</sup>.

**Contexts in which this element can be used**<sup>p113</sup>:

Where [phrasing content](#)<sup>p116</sup> is expected.

**Content model**<sup>p113</sup>:

[Phrasing content](#)<sup>p116</sup>, but there must be no [interactive content](#)<sup>p116</sup> descendant.

### Tag omission in `text/html`<sup>p113</sup>:

Neither tag is omissionable.

### Content attributes<sup>p113</sup>:

#### Global attributes<sup>p120</sup>

`autofocus`<sup>p533</sup> — Automatically focus the form control when the page is loaded  
`disabled`<sup>p530</sup> — Whether the form control is disabled  
`form`<sup>p527</sup> — Associates the control with a `Form`<sup>p447</sup> element  
`formaction`<sup>p531</sup> — URL<sup>p48</sup> to use for form submission<sup>p557</sup>  
`formenctype`<sup>p532</sup> — Form data set encoding type to use for form submission<sup>p557</sup>  
`formmethod`<sup>p531</sup> — HTTP method to use for form submission<sup>p557</sup>  
`formnovalidate`<sup>p532</sup> — Bypass form control validation for form submission<sup>p557</sup>  
`formtarget`<sup>p532</sup> — Browsing context<sup>p762</sup> for form submission<sup>p557</sup>  
`menu`<sup>p497</sup> — Specifies the element's designated pop-up menu<sup>p497</sup>  
`name`<sup>p529</sup> — Name of form control to use for form submission<sup>p557</sup> and in the `form.elements`<sup>p449</sup> API  
`type`<sup>p496</sup> — Type of button  
`value`<sup>p497</sup> — Value to be used for form submission<sup>p557</sup>

### DOM interface<sup>p113</sup>:

```
IDL
interface HTMLButtonElement : HTMLElement {
 attribute boolean autofocus;
 attribute boolean disabled;
 readonly attribute HTMLFormElement? form;
 attribute DOMString formAction;
 attribute DOMString formEnctype;
 attribute DOMString formMethod;
 attribute boolean formNoValidate;
 attribute DOMString formTarget;
 attribute DOMString name;
 attribute DOMString type;
 attribute DOMString value;
 attribute HTMLMenuElement? menu;

 readonly attribute boolean willValidate;
 readonly attribute ValidityState validity;
 readonly attribute DOMString validationMessage;
 boolean checkValidity();
 boolean reportValidity();
 void setCustomValidity(DOMString error);

 readonly attribute NodeList labels;
};
```

The `button`<sup>p495</sup> element represents<sup>p111</sup> a button labeled by its contents.

The element is a `button`<sup>p447</sup>.

The `type` attribute controls the behaviour of the button when it is activated. It is an enumerated attribute<sup>p60</sup>. The following table lists the keywords and states for the attribute — the keywords in the left column map to the states in the cell in the second column on the same row as the keyword.

Keyword	State	Brief description
<code>submit</code>	<u>Submit Button</u> <sup>p497</sup>	Submits the form.
<code>reset</code>	<u>Reset Button</u> <sup>p497</sup>	Resets the form.
<code>button</code>	<u>Button</u> <sup>p497</sup>	Does nothing.
<code>menu</code>	<u>Menu</u> <sup>p497</sup>	Shows a menu.

The [missing value default](#)<sup>p60</sup> is the [Submit Button](#)<sup>p497</sup> state.

If the [type](#)<sup>p496</sup> attribute is in the [Submit Button](#)<sup>p497</sup> state, the element is specifically a [submit button](#)<sup>p447</sup>.

**Constraint validation:** If the [type](#)<sup>p496</sup> attribute is in the [Reset Button](#)<sup>p497</sup> state, the [Button](#)<sup>p497</sup> state, or the [Menu](#)<sup>p497</sup> state, the element is [barred from constraint validation](#)<sup>p553</sup>.

When a [button](#)<sup>p495</sup> element is not [disabled](#)<sup>p530</sup>, its [activation behaviour](#)<sup>p725</sup> element is to run the steps defined in the following list for the current state of the element's [type](#)<sup>p496</sup> attribute:

### Submit Button

If the element has a [form owner](#)<sup>p527</sup> and the element's [node document](#) is [fully active](#)<sup>p763</sup>, the element must [submit](#)<sup>p558</sup> the [form owner](#)<sup>p527</sup> from the [button](#)<sup>p495</sup> element.

### Reset Button

If the element has a [form owner](#)<sup>p527</sup> and the element's [node document](#) is [fully active](#)<sup>p763</sup>, the element must [reset](#)<sup>p567</sup> the [form owner](#)<sup>p527</sup>.

### Button

Do nothing.

### Menu

The element must follow these steps:

1. If the [button](#)<sup>p495</sup> is not [being rendered](#)<sup>p1058</sup>, abort these steps.
2. If the [button](#)<sup>p495</sup> element's [node document](#) is not [fully active](#)<sup>p763</sup>, abort these steps.
3. Let [menu](#) be the element's [designated pop-up menu](#)<sup>p497</sup>, if any. If there isn't one, then abort these steps.
4. [Fire](#)<sup>p43</sup> a [trusted](#)<sup>p43</sup> event with the name [show](#)<sup>p1145</sup> at [menu](#), using the [RelatedEvent](#)<sup>p579</sup> interface, with the [relatedTarget](#)<sup>p579</sup> attribute initialised to the [button](#)<sup>p495</sup> element. The event must be cancelable.
5. If the event is not canceled, then [build and show](#)<sup>p572</sup> the menu for [menu](#), with the [button](#)<sup>p495</sup> element as the subject.

The [form](#)<sup>p527</sup> attribute is used to explicitly associate the [button](#)<sup>p495</sup> element with its [form owner](#)<sup>p527</sup>. The [name](#)<sup>p529</sup> attribute represents the element's name. The [disabled](#)<sup>p530</sup> attribute is used to make the control non-interactive and to prevent its value from being submitted. The [autofocus](#)<sup>p533</sup> attribute controls focus. The [formaction](#)<sup>p531</sup>, [formenctype](#)<sup>p532</sup>, [formmethod](#)<sup>p531</sup>, [formnovalidate](#)<sup>p532</sup>, and [formtarget](#)<sup>p532</sup> attributes are [attributes for form submission](#)<sup>p531</sup>.

**Note** The [formnovalidate](#)<sup>p532</sup> attribute can be used to make submit buttons that do not trigger the constraint validation.

The [formaction](#)<sup>p531</sup>, [formenctype](#)<sup>p532</sup>, [formmethod](#)<sup>p531</sup>, [formnovalidate](#)<sup>p532</sup>, and [formtarget](#)<sup>p532</sup> must not be specified if the element's [type](#)<sup>p496</sup> attribute is not in the [Submit Button](#)<sup>p497</sup> state.

The [value](#) attribute gives the element's value for the purposes of form submission. The element's [value](#)<sup>p527</sup> is the value of the element's [value](#)<sup>p497</sup> attribute, if there is one, or the empty string otherwise.

**Note** A button (and its value) is only included in the form submission if the button itself was used to initiate the form submission.

If the element's [type](#)<sup>p496</sup> attribute is in the [Menu](#)<sup>p497</sup> state, the [menu](#) attribute must be specified to give the element's menu. The value must be the [ID](#)<sup>p51</sup> of a [menu](#)<sup>p571</sup> element in the same [home subtree](#)<sup>p42</sup> whose [type](#)<sup>p572</sup> attribute is in the [popup menu](#)<sup>p572</sup> state. The attribute must not be specified if the element's [type](#)<sup>p496</sup> attribute is not in the [Menu](#)<sup>p497</sup> state.

A [button](#)<sup>p495</sup> element's [designated pop-up menu](#) is the first element in the [button](#)<sup>p495</sup>'s [home subtree](#)<sup>p42</sup> whose ID is that given by the [button](#)<sup>p495</sup> element's [menu](#)<sup>p497</sup> attribute, if there is such an element and its [type](#)<sup>p572</sup> attribute is in the [popup menu](#)<sup>p572</sup> state; otherwise, the element has no [designated pop-up menu](#)<sup>p497</sup>.

The [value](#) and [menu](#) IDL attributes must [reflect](#)<sup>p88</sup> the content attributes of the same name.

The `type` IDL attribute must [reflect<sup>p88</sup>](#) the `content` attribute of the same name, [limited to only known values<sup>p89</sup>](#).

The `willValidatep555`, `validityp556`, and `validationMessagep557` IDL attributes, and the `checkValidity()p556`, `reportValidity()p557`, and `setCustomValidity()p555` methods, are part of the [constraint validation API<sup>p554</sup>](#). The `labelsp452` IDL attribute provides a list of the element's `labelp451`s. The `autofocusp533`, `disabledp530`, `formp529`, and `namep529` IDL attributes are part of the element's forms API.

### Example

The following button is labeled "Show hint" and pops up a dialog box when activated:

```
<button type=button
 onclick="alert('This 15-20 minute piece was composed by George Gershwin.')">
 Show hint
</button>
```

## 4.10.7 The `select` element

Spec bugs: [25027](#), [27476](#),

 readonly attribute boolean willValidate;
 readonly attribute ValidityState validity;
 readonly attribute DOMString validationMessage;
 boolean checkValidity();
 boolean reportValidity();
 void setCustomValidity(DOMString error);

 readonly attribute NodeList labels;
 };
}

```

The [select](#) element represents a control for selecting amongst a set of options.

The [multiple](#) attribute is a [boolean attribute](#). If the attribute is present, then the [select](#) element represents a control for selecting zero or more options from the [list of options](#). If the attribute is absent, then the [select](#) element represents a control for selecting a single option from the [list of options](#).

The [size](#) attribute gives the number of options to show to the user. The [size](#) attribute, if specified, must have a value that is a [valid non-negative integer](#) greater than zero.

The [display size](#) of a [select](#) element is the result of applying the [rules for parsing non-negative integers](#) to the value of element's [size](#) attribute, if it has one and parsing it is successful. If applying those rules to the attribute's value is not successful, or if the [size](#) attribute is absent, then the element's [display size](#) is 4 if the element's [multiple](#) content attribute is present, and 1 otherwise.

The [list of options](#) for a [select](#) element consists of all the [option](#) element children of the [select](#) element, and all the [option](#) element children of all the [optgroup](#) element children of the [select](#) element, in [tree order](#).

The [required](#) attribute is a [boolean attribute](#). When specified, the user will be required to select a value before submitting the form.

If a [select](#) element has a [required](#) attribute specified, does not have a [multiple](#) attribute specified, and has a [display size](#) of 1; and if the [value](#) of the first [option](#) element in the [select](#) element's [list of options](#) (if any) is the empty string, and that [option](#) element's parent node is the [select](#) element (and not an [optgroup](#) element), then that [option](#) is the [select](#) element's [placeholder label option](#).

If a [select](#) element has a [required](#) attribute specified, does not have a [multiple](#) attribute specified, and has a [display size](#) of 1, then the [select](#) element must have a [placeholder label option](#).

**Constraint validation:** If the element has its [required](#) attribute specified, and either none of the [option](#) elements in the [select](#) element's [list of options](#) have their [selectedness](#) set to true, or the only [option](#) element in the [select](#) element's [list of options](#) with its [selectedness](#) set to true is the [placeholder label option](#), then the element is [suffering from being missing](#).

If the [multiple](#) attribute is absent, and the element is not [disabled](#), then the user agent should allow the user to pick an [option](#) element in its [list of options](#) that is itself not [disabled](#). Upon this [option](#) element being [picked](#) (either through a click, or through unfocusing the element after changing its value, or through a [menu command](#), or through any other mechanism), and before the relevant user

interaction event is queued (e.g. before the `click` event), the user agent must set the `selectedness` of the picked `option` element to true, set its `dirtiness` to true, and then `send select update notifications`.

If the `multiple` attribute is absent, whenever an `option` element in the `select` element's `list of options` has its `selectedness` set to true, and whenever an `option` element with its `selectedness` set to true is added to the `select` element's `list of options`, the user agent must set the `selectedness` of all the other `option` elements in its `list of options` to false.

If the `multiple` attribute is absent and the element's `display size` is greater than 1, then the user agent should also allow the user to request that the `option` whose `selectedness` is true, if any, be unselected. Upon this request being conveyed to the user agent, and before the relevant user interaction event is queued (e.g. before the `click` event), the user agent must set the `selectedness` of that `option` element to false, set its `dirtiness` to true, and then `send select update notifications`.

If `nodes are inserted` or `nodes are removed` causing the `list of options` to gain or lose one or more `option` elements, or if an `option` element in the `list of options` asks for a reset, then, if the `select` element's `multiple` attribute is absent, the user agent must run the first applicable set of steps from the following list:

- ↪ If the `select` element's `display size` is 1, and no `option` elements in the `select` element's `list of options` have their `selectedness` set to true  
Set the `selectedness` of the first `option` element in the `list of options` in `tree order` that is not `disabled`, if any, to true.
- ↪ If two or more `option` elements in the `select` element's `list of options` have their `selectedness` set to true  
Set the `selectedness` of all but the last `option` element with its `selectedness` set to true in the `list of options` in `tree order` to false.

If the `multiple` attribute is present, and the element is not `disabled`, then the user agent should allow the user to **toggle** the `selectedness` of the `option` elements in its `list of options` that are themselves not `disabled`. Upon such an element being **toggled** (either through a click, or through a `menu command`, or any other mechanism), and before the relevant user interaction event is queued (e.g. before a related `click` event), the `selectedness` of the `option` element must be changed (from true to false or false to true), the `dirtiness` of the element must be set to true, and the user agent must `send select update notifications`.

When the user agent is to `send select update notifications`, `queue a task` to first `fire a simple event` that bubbles named `input` at the `select` element, and then `fire a simple event` that bubbles named `change` at the `select` element, using the `user interaction task source` as the task source. If the `stack of script settings objects` was not empty when the user agent was to `send select update notifications`, then the resulting `input` and `change` events must not be `trusted`.

The `reset algorithm` for `select` elements is to go through all the `option` elements in the element's `list of options`, set their `selectedness` to true if the `option` element has a `selected` attribute, and false otherwise, set their `dirtiness` to false, and then have the `option` elements `ask for a reset`.

The `form` attribute is used to explicitly associate the `select` element with its `form owner`. The `name` attribute represents the element's name. The `disabled` attribute is used to make the control non-interactive and to prevent its value from being submitted. The `autofocus` attribute controls focus. The `autocomplete` attribute controls how the user agent provides autofill behaviour.

A `select` element that is not `disabled` is `mutable`.

### Note

`select . type`

Returns "select-multiple" if the element has a `multiple` attribute, and "select-one" otherwise.

`select . options`

Returns an `HTMLOptionsCollection` of the `list of options`.

`select . length` [= `value`]

Returns the number of elements in the `list of options`.

When set to a smaller number, truncates the number of `option` elements in the `select`.

When set to a greater number, adds new blank `option` elements to the `select`.

```

element = select.itemp501(index)
select[index]
 Returns the item with index index from the list of optionsp499. The items are sorted in tree orderp42.
element = select.namedItemp501(name)
 Returns the first item with IDp51 or namep1097 name from the list of optionsp499.
 Returns null if no element with that IDp51 could be found.
select.addp501(element [, before])
 Inserts element before the node given by before.
 The before argument can be a number, in which case element is inserted before the item with that number, or an element from the list of optionsp499, in which case element is inserted before that element.
 If before is omitted, null, or a number out of range, then element will be added at the end of the list.
 This method will throw a HierarchyRequestErrorp50 exception if element is an ancestor of the element into which it is to be inserted.
select.selectedOptionsp501
 Returns an HTMLCollectionp51 of the list of optionsp499 that are selected.
select.selectedIndexp502 [= value]
 Returns the index of the first selected item, if any, or -1 if there is no selected item.
 Can be set, to change the selection.
select.valuep502 [= value]
 Returns the valuep506 of the first selected item, if any, or the empty string if there is no selected item.
 Can be set, to change the selection.

```

The [type](#) IDL attribute, on getting, must return the string "select-one" if the [multiple<sup>p499</sup>](#) attribute is absent, and the string "select-multiple" if the [multiple<sup>p499</sup>](#) attribute is present.

The [options](#) IDL attribute must return an [HTMLOptionsCollection<sup>p93</sup>](#) rooted at the [select<sup>p498</sup>](#) node, whose filter matches the elements in the [list of options<sup>p499</sup>](#).

The [options<sup>p501</sup>](#) collection is also mirrored on the [HTMLSelectElement<sup>p498</sup>](#) object. The [supported property indices<sup>p49</sup>](#) at any instant are the indices supported by the object returned by the [options<sup>p501</sup>](#) attribute at that instant.

The [length](#) IDL attribute must return the number of nodes [represented<sup>p51</sup>](#) by the [options<sup>p501</sup>](#) collection. On setting, it must act like the attribute of the same name on the [options<sup>p501</sup>](#) collection.

The [item\(index\)](#) method must return the value returned by [the method of the same name<sup>p51</sup>](#) on the [options<sup>p501</sup>](#) collection, when invoked with the same argument.

The [namedItem\(name\)](#) method must return the value returned by [the method of the same name<sup>p94</sup>](#) on the [options<sup>p501</sup>](#) collection, when invoked with the same argument.

When the user agent is to **set the value of a new indexed property** for a given property index *index* to a new value *value*, it must instead [set the value of a new indexed property<sup>p94</sup>](#) with the given property index *index* to the new value *value* on the [options<sup>p501</sup>](#) collection.

Similarly, the [add\(\)](#) method must act like its namesake method on that same [options<sup>p501</sup>](#) collection.

The [remove\(\)](#) method must act like its namesake method on that same [options<sup>p501</sup>](#) collection when it has arguments, and like its namesake method on the [ChildNode<sup>p51</sup>](#) interface implemented by the [HTMLSelectElement<sup>p498</sup>](#) ancestor interface [Element<sup>p51</sup>](#) when it has no arguments.

The [selectedOptions](#) IDL attribute must return an [HTMLCollection<sup>p51</sup>](#) rooted at the [select<sup>p498</sup>](#) node, whose filter matches the elements in the [list of options<sup>p499</sup>](#) that have their [selectedness<sup>p507</sup>](#) set to true.

The `selectedIndex` IDL attribute, on getting, must return the `indexp507` of the first `optionp505` element in the `list of optionsp499` in `tree orderp42` that has its `selectednessp507` set to true, if any. If there isn't one, then it must return -1.

On setting, the `selectedIndexp502` attribute must set the `selectednessp507` of all the `optionp505` elements in the `list of optionsp499` to false, and then the `optionp505` element in the `list of optionsp499` whose `indexp507` is the given new value, if any, must have its `selectednessp507` set to true and its `dirtyinessp506` set to true.

**Note** This can result in no element having a `selectednessp507` set to true even in the case of the `selectp498` element having no `multiplep499` attribute and a `display sizep499` of 1.

The `value` IDL attribute, on getting, must return the `valuep506` of the first `optionp505` element in the `list of optionsp499` in `tree orderp42` that has its `selectednessp507` set to true, if any. If there isn't one, then it must return the empty string.

On setting, the `valuep502` attribute must set the `selectednessp507` of all the `optionp505` elements in the `list of optionsp499` to false, and then the first `optionp505` element in the `list of optionsp499`, in `tree orderp42`, whose `valuep506` is equal to the given new value, if any, must have its `selectednessp507` set to true and its `dirtyinessp506` set to true.

**Note** This can result in no element having a `selectednessp507` set to true even in the case of the `selectp498` element having no `multiplep499` attribute and a `display sizep499` of 1.

The `multiple`, `required`, and `size` IDL attributes must `reflectp88` the respective content attributes of the same name. The `sizep502` IDL attribute has a default value of zero.

**Note** For historical reasons, the default value of the `sizep502` IDL attribute does not return the actual size used, which, in the absence of the `sizep499` content attribute, is either 1 or 4 depending on the presence of the `multiplep499` attribute.

The `willValidatep555`, `validityp556`, and `validationMessagep557` IDL attributes, and the `checkValidity()p556`, `reportValidity()p557`, and `setCustomValidity()p555` methods, are part of the `constraint validation APIp554`. The `labelsp452` IDL attribute provides a list of the element's `labelp451`s. The `autofocusp533`, `disabledp530`, `formp529`, and `namep529` IDL attributes are part of the element's forms API.

### Example

The following example shows how a `selectp498` element can be used to offer the user with a set of options from which the user can select a single option. The default option is preselected.

```
<p>
 <label for="unittype">Select unit type:</label>
 <select id="unittype" name="unittype">
 <option value="1"> Miner </option>
 <option value="2"> Puffer </option>
 <option value="3" selected> Snipey </option>
 <option value="4"> Max </option>
 <option value="5"> Firebot </option>
 </select>
</p>
```

When there is no default option, a placeholder can be used instead:

```
<select name="unittype" required>
 <option value=""> Select unit type </option>
 <option value="1"> Miner </option>
 <option value="2"> Puffer </option>
 <option value="3"> Snipey </option>
 <option value="4"> Max </option>
 <option value="5"> Firebot </option>
</select>
```

### Example

Here, the user is offered a set of options from which he can select any number. By default, all five options are selected.

```
<p>
 <label for="allowedunits">Select unit types to enable on this map:</label>
 <select id="allowedunits" name="allowedunits" multiple>
```

```

<option value="1" selected> Miner </option>
<option value="2" selected> Puffer </option>
<option value="3" selected> Snipey </option>
<option value="4" selected> Max </option>
<option value="5" selected> Firebot </option>
</select>
</p>

```

### Example

Sometimes, a user has to select one or more items. This example shows such an interface.

```

<p>Select the songs from that you would like on your Act II Mix Tape:</p>
<select multiple required name="act2">
 <option value="s1">It Sucks to Be Me (Reprise)
 <option value="s2">There is Life Outside Your Apartment
 <option value="s3">The More You Ruv Someone
 <option value="s4">Schadenfreude
 <option value="s5">I Wish I Could Go Back to College
 <option value="s6">The Money Song
 <option value="s7">School for Monsters
 <option value="s8">The Money Song (Reprise)
 <option value="s9">There's a Fine, Fine Line (Reprise)
 <option value="s10">What Do You Do With a B.A. in English? (Reprise)
 <option value="s11">For Now
</select>

```

## 4.10.8 The `datalist` element

**Categories**<sup>p113</sup>:

[Flow content](#)<sup>p115</sup>.

[Phrasing content](#)<sup>p116</sup>.

**Contexts in which this element can be used**<sup>p113</sup>:

Where [phrasing content](#)<sup>p116</sup> is expected.

**Content model**<sup>p113</sup>:

Either: [phrasing content](#)<sup>p116</sup>.

Or: Zero or more [option](#)<sup>p505</sup> and script-supporting elements.

**Tag omission in text/html**<sup>p113</sup>:

Neither tag is ommissible.

**Content attributes**<sup>p113</sup>:

[Global attributes](#)<sup>p120</sup>

**DOM interface**<sup>p113</sup>:

IDL	<pre> interface HTMLDataListElement : HTMLElement {   readonly attribute HTMLCollection options; } </pre>
-----	-----------------------------------------------------------------------------------------------------------

Support:		
	Chrome	20+
	IE (limited)	10+
	Chrome for Android	40+
	Firefox	4+
	Android Browser 4.4.3-4.4.4+	
	UC Browser for Android	9.9+
	Opera Mini	None
	Safari	None
	Opera	9+
	Firefox for Android	33+

Source: [caniuse.com](#)

The [datalist](#)<sup>p503</sup> element represents a set of [option](#)<sup>p505</sup> elements that represent predefined options for other controls. In the rendering, the [datalist](#)<sup>p503</sup> element [represents](#)<sup>p111</sup> nothing and it, along with its children, should be hidden.

The [datalist](#)<sup>p503</sup> element can be used in two ways. In the simplest case, the [datalist](#)<sup>p503</sup> element has just [option](#)<sup>p505</sup> element children.

### Example

```

<label>
 Sex:
 <input name=sex list=sexes>

```

```

<datalist id=sexes>
 <option value="Female">
 <option value="Male">
</datalist>
</label>

```

In the more elaborate case, the [datalist](#)<sup>p503</sup> element can be given contents that are to be displayed for down-level clients that don't support [datalist](#)<sup>p503</sup>. In this case, the [option](#)<sup>p505</sup> elements are provided inside a [select](#)<sup>p498</sup> element inside the [datalist](#)<sup>p503</sup> element.

### Example

```

<label>
 Sex:
 <input name=sex list=sexes>
</label>
<datalist id=sexes>
 <label>
 or select from the list:
 <select name=sex>
 <option value="">
 <option>Female
 <option>Male
 </select>
 </label>
</datalist>

```

The [datalist](#)<sup>p503</sup> element is hooked up to an [input](#)<sup>p452</sup> element using the [list](#)<sup>p489</sup> attribute on the [input](#)<sup>p452</sup> element.

Each [option](#)<sup>p505</sup> element that is a descendant of the [datalist](#)<sup>p503</sup> element, that is not [disabled](#)<sup>p506</sup>, and whose [value](#)<sup>p506</sup> is a string that isn't the empty string, represents a suggestion. Each suggestion has a [value](#)<sup>p506</sup> and a [label](#)<sup>p506</sup>.

### Note

[datalist](#).[options](#)<sup>p504</sup>

Returns an [HTMLCollection](#)<sup>p51</sup> of the [option](#)<sup>p505</sup> elements of the [datalist](#)<sup>p503</sup> element.

The [options](#) IDL attribute must return an [HTMLCollection](#)<sup>p51</sup> rooted at the [datalist](#)<sup>p503</sup> node, whose filter matches [option](#)<sup>p505</sup> elements.

**Constraint validation:** If an element has a [datalist](#)<sup>p503</sup> element ancestor, it is [barred from constraint validation](#)<sup>p553</sup>.

## 4.10.9 The [optgroup](#) element

**Categories**<sup>p113</sup>:

None.

**Contexts in which this element can be used**<sup>p113</sup>:

As a child of a [select](#)<sup>p498</sup> element.

**Content model**<sup>p113</sup>:

Zero or more [option](#)<sup>p505</sup> and [script-supporting](#)<sup>p117</sup> elements.

**Tag omission in text/html**<sup>p113</sup>:

An [optgroup](#)<sup>p504</sup> element's [end tag](#)<sup>p944</sup> can be omitted if the [optgroup](#)<sup>p504</sup> element is immediately followed by another [optgroup](#)<sup>p504</sup> element, or if there is no more content in the parent element.

**Content attributes**<sup>p113</sup>:

[Global attributes](#)<sup>p120</sup>

[disabled](#)<sup>p505</sup> — Whether the form control is disabled

[label](#)<sup>p505</sup> — User-visible label

## DOM interface<sup>p113</sup>:

IDL	<pre>interface <b>HTMLOptGroupElement</b> : <b>HTMLElement</b> {     attribute boolean <b>disabled</b>;     attribute DOMString <b>label</b>; };</pre>
-----	--------------------------------------------------------------------------------------------------------------------------------------------------------------------

The [optgroup](#)<sup>p504</sup> element [represents](#)<sup>p111</sup> a group of [option](#)<sup>p505</sup> elements with a common label.

The element's group of [option](#)<sup>p505</sup> elements consists of the [option](#)<sup>p505</sup> elements that are children of the [optgroup](#)<sup>p504</sup> element.

When showing [option](#)<sup>p505</sup> elements in [select](#)<sup>p498</sup> elements, user agents should show the [option](#)<sup>p505</sup> elements of such groups as being related to each other and separate from other [option](#)<sup>p505</sup> elements.

The [disabled](#) attribute is a [boolean attribute](#)<sup>p59</sup> and can be used to [disable](#)<sup>p506</sup> a group of [option](#)<sup>p505</sup> elements together.

The [label](#) attribute must be specified. Its value gives the name of the group, for the purposes of the user interface. User agents should use this attribute's value when labeling the group of [option](#)<sup>p505</sup> elements in a [select](#)<sup>p498</sup> element.

The [disabled](#) and [label](#) attributes must [reflect](#)<sup>p88</sup> the respective content attributes of the same name.

**Note** There is no way to select an [optgroup](#)<sup>p504</sup> element. Only [option](#)<sup>p505</sup> elements can be selected. An [optgroup](#)<sup>p504</sup> element merely provides a label for a group of [option](#)<sup>p505</sup> elements.

### Example

The following snippet shows how a set of lessons from three courses could be offered in a [select](#)<sup>p498</sup> drop-down widget:

```
<form action="coursesselector.dll" method="get">
 <p>Which course would you like to watch today?
 <p><label>Course:
 <select name="c">
 <optgroup label="8.01 Physics I: Classical Mechanics">
 <option value="8.01.1">Lecture 01: Powers of Ten
 <option value="8.01.2">Lecture 02: 1D Kinematics
 <option value="8.01.3">Lecture 03: Vectors
 <optgroup label="8.02 Electricity and Magnetism">
 <option value="8.02.1">Lecture 01: What holds our world together?
 <option value="8.02.2">Lecture 02: Electric Field
 <option value="8.02.3">Lecture 03: Electric Flux
 <optgroup label="8.03 Physics III: Vibrations and Waves">
 <option value="8.03.1">Lecture 01: Periodic Phenomenon
 <option value="8.03.2">Lecture 02: Beats
 <option value="8.03.3">Lecture 03: Forced Oscillations with Damping
 </select>
 </label>
 <p><input type="submit" value="▶ Play">
</form>
```

## 4.10.10 The [option](#) element

### Categories<sup>p113</sup>:

None.

### Contexts in which this element can be used<sup>p113</sup>:

As a child of a [select](#)<sup>p498</sup> element.

As a child of a [datalist](#)<sup>p503</sup> element.

As a child of an [optgroup](#) element.

#### Content model<sup>p113</sup>:

If the element has a [label](#) attribute and a [value](#) attribute: [Nothing](#).

If the element has a [label](#) attribute but no [value](#) attribute: [Text](#).

If the element has no [label](#) attribute: [Text](#) that is not [inter-element whitespace](#).

#### Tag omission in text/html<sup>p113</sup>:

An [option](#) element's [end tag](#) can be omitted if the [option](#) element is immediately followed by another [option](#) element, or if it is immediately followed by an [optgroup](#) element, or if there is no more content in the parent element.

#### Content attributes<sup>p113</sup>:

##### [Global attributes](#)<sup>p120</sup>

[disabled](#) — Whether the form control is disabled

[label](#) — User-visible label

[selected](#) — Whether the option is selected by default

[value](#) — Value to be used for [form submission](#)

#### DOM interface<sup>p113</sup>:

```
[NamedConstructor=Option(optional DOMString text = "", optional DOMString value, optional
boolean defaultSelected = false, optional boolean selected = false)]
interface HTMLOptionElement : HTMLElement {
 attribute boolean disabled;
 readonly attribute HTMLFormElement? form;
 attribute DOMString label;
 attribute boolean defaultSelected;
 attribute boolean selected;
 attribute DOMString value;

 attribute DOMString text;
 readonly attribute long index;
};
```

The [option](#) element [represents](#) an option in a [select](#) element or as part of a list of suggestions in a [datalist](#) element.

In certain circumstances described in the definition of the [select](#) element, an [option](#) element can be a [select](#) element's [placeholder label option](#). A [placeholder label option](#) does not represent an actual option, but instead represents a label for the [select](#) control.

The [disabled](#) attribute is a [boolean attribute](#). An [option](#) element is [disabled](#) if its [disabled](#) attribute is present or if it is a child of an [optgroup](#) element whose [disabled](#) attribute is present.

An [option](#) element that is [disabled](#) must prevent any [click](#) events that are [queued](#) on the [user interaction task source](#) from being dispatched on the element.

The [label](#) attribute provides a label for element. The [label](#) of an [option](#) element is the value of the [label](#) content attribute, if there is one and its value is not the empty string, or, otherwise, the value of the element's [text](#) IDL attribute.

The [label](#) content attribute, if specified, must not be empty.

The [value](#) attribute provides a value for element. The [value](#) of an [option](#) element is the value of the [value](#) content attribute, if there is one, or, if there is not, the value of the element's [text](#) IDL attribute.

The [selected](#) attribute is a [boolean attribute](#). It represents the default [selectedness](#) of the element.

The [dirtiness](#) of an [option](#) element is a boolean state, initially false. It controls whether adding or removing the [selected](#) content attribute has any effect.

The **selectedness** of an `option` element is a boolean state, initially false. Except where otherwise specified, when the element is created, its `selectedness` must be set to true if the element has a `selected` attribute. Whenever an `option` element's `selected` attribute is added, if its `dirtiness` is false, its `selectedness` must be set to true. Whenever an `option` element's `selected` attribute is removed, if its `dirtiness` is false, its `selectedness` must be set to false.

**Note** The `Option()` constructor, when called with three or fewer arguments, overrides the initial state of the `selectedness` state to always be false even if the third argument is true (implying that a `selected` attribute is to be set). The fourth argument can be used to explicitly set the initial `selectedness` state when using the constructor.

A `select` element whose `multiple` attribute is not specified must not have more than one descendant `option` element with its `selected` attribute set.

An `option` element's `index` is the number of `option` elements that are in the same `list of options` but that come before it in `tree order`. If the `option` element is not in a `list of options`, then the `option` element's `index` is zero.

**Note**

#### `option.selected`

Returns true if the element is selected, and false otherwise.

Can be set, to override the current state of the element.

#### `option.index`

Returns the index of the element in its `select` element's `options` list.

#### `option.form`

Returns the element's `form` element, if any, or null otherwise.

#### `option.text`

Same as `textContent`, except that spaces are collapsed and `script` elements are skipped.

#### `option = new Option([text[, value[, defaultSelected[, selected]]]])`

Returns a new `option` element.

The `text` argument sets the contents of the element.

The `value` argument sets the `value` attribute.

The `defaultSelected` argument sets the `selected` attribute.

The `selected` argument sets whether or not the element is selected. If it is omitted, even if the `defaultSelected` argument is true, the element is not selected.

The `disabled` IDL attribute must `reflect` the `content` attribute of the same name. The `defaultSelected` IDL attribute must `reflect` the `selected` content attribute.

The `label` IDL attribute, on getting, if there is a `label` content attribute, must return that attribute's value; otherwise, it must return the element's `label`. On setting, the element's `label` content attribute must be set to the new value.

The `value` IDL attribute, on getting, must return the element's `value`. On setting, the element's `value` content attribute must be set to the new value.

The `selected` IDL attribute, on getting, must return true if the element's `selectedness` is true, and false otherwise. On setting, it must set the element's `selectedness` to the new value, set its `dirtiness` to true, and then cause the element to `ask for a reset`.

The `index` IDL attribute must return the element's `index`.

The `text` IDL attribute, on getting, must return the result of `stripping and collapsing whitespace` from the concatenation of `data` of all the `Text` node descendants of the `option` element, in `tree order`, excluding any that are descendants of descendants of the `option` element that are themselves `script` elements in the `HTML namespace` or `script` elements in the `SVG namespace`.

On setting, the `text` attribute must act as if the `textContent` IDL attribute on the element had been set to the new value.

The `form` IDL attribute's behaviour depends on whether the `option` element is in a `select` element or not. If the `option` has a `select` element as its parent, or has an `optgroup` element as its parent and that `optgroup` element has a `select` element as its parent, then the `form` IDL attribute must return the same value as the `form` IDL attribute on that `select` element. Otherwise, it must return null.

A constructor is provided for creating `HTMLOptionElement` objects (in addition to the factory methods from DOM such as `createElement(): Option(text, value, defaultSelected, selected)`). When invoked as a constructor, it must return a new `HTMLOptionElement` object (a new `option` element). If the first argument is not the empty string, the new object must have as its only child a `Text` node whose data is the value of that argument. Otherwise, it must have no children. If the `value` argument is present, the new object must have a `value` attribute set with the value of the argument as its value. If the `defaultSelected` argument is true, the new object must have a `selected` attribute set with no value. If the `selected` argument is true, the new object must have its `selectedness` set to true; otherwise the `selectedness` must be set to false, even if the `defaultSelected` argument is true. The element's `node document` must be the `active document` of the `browsing context` of the `Window` object on which the interface object of the invoked constructor is found.

#### 4.10.11 The `textarea` element

Spec bugs: 15291, 18069

Categories<sup>p113</sup>:

[Flow content](#)<sup>p115</sup>.  
[Phrasing content](#)<sup>p116</sup>.  
[Interactive content](#)<sup>p116</sup>.  
[Listed](#)<sup>p446</sup>, [labelable](#)<sup>p447</sup>, [submittable](#)<sup>p447</sup>, [resettable](#)<sup>p447</sup>, and [reassociateable](#)<sup>p447</sup> [form-associated element](#)<sup>p446</sup>.  
[Palpable content](#)<sup>p117</sup>.

Contexts in which this element can be used<sup>p113</sup>:

Where [phrasing content](#)<sup>p116</sup> is expected.

Content model<sup>p113</sup>:

[Text](#)<sup>p116</sup>.

Tag omission in `text/html`<sup>p113</sup>:

Neither tag is omissible.

Content attributes<sup>p113</sup>:

[Global attributes](#)<sup>p120</sup>  
[autocomplete](#)<sup>p535</sup> — Hint for form autofill feature  
[autofocus](#)<sup>p533</sup> — Automatically focus the form control when the page is loaded  
[cols](#)<sup>p510</sup> — Maximum number of characters per line  
[dirname](#)<sup>p529</sup> — Name of form field to use for sending the element's [directionality](#)<sup>p125</sup> in [form submission](#)<sup>p557</sup>

attribute unsigned long selectionStart;
attribute unsigned long selectionEnd;
attribute DOMString selectionDirection;
void setRangeText(DOMString replacement);
void setRangeText(DOMString replacement, unsigned long start, unsigned long end, optional
SelectionMode selectionMode = "preserve");
void setSelectionRange(unsigned long start, unsigned long end, optional DOMString
direction);
};

}

```

The `textarea`<sup>p508</sup> element represents<sup>p111</sup> a multiline plain text edit control for the element's **raw value**. The contents of the control represent the control's default value.

The raw value<sup>p509</sup> of a `textarea`<sup>p508</sup> control must be initially the empty string.

**Note** *This element has rendering requirements involving the bidirectional algorithm*<sup>p132</sup>.

The **readonly** attribute is a boolean attribute<sup>p59</sup> used to control whether the text can be edited by the user or not.

### Example

In this example, a text field is marked read-only because it represents a read-only file:

```

Filename: <code>/etc/bash.bashrc</code>
<textarea name="buffer" readonly>
System-wide .bashrc file for interactive bash(1) shells.

To enable the settings / commands in this file for login shells as well,
this file has to be sourced in /etc/profile.

If not running interactively, don't do anything
[-z "$PS1"] && return

```

```
...</textarea>
```

**Constraint validation:** If the `readonly`<sup>p509</sup> attribute is specified on a `textarea`<sup>p508</sup> element, the element is [barred from constraint validation](#)<sup>p553</sup>.

A `textarea`<sup>p508</sup> element is [mutable](#)<sup>p527</sup> if it is neither [disabled](#)<sup>p530</sup> nor has a `readonly`<sup>p509</sup> attribute specified.

When a `textarea`<sup>p508</sup> is [mutable](#)<sup>p527</sup>, its [raw value](#)<sup>p509</sup> should be editable by the user: the user agent should allow the user to edit, insert, and remove text, and to insert and remove line breaks in the form of U+000A LINE FEED (LF) characters. Any time the user causes the element's [raw value](#)<sup>p509</sup> to change, the user agent must [queue a task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> that bubbles named `input`<sup>p1144</sup> at the `textarea`<sup>p508</sup> element. User agents may wait for a suitable break in the user's interaction before queuing the task; for example, a user agent could wait for the user to have not hit a key for 100ms, so as to only fire the event when the user pauses, instead of continuously for each keystroke.

A `textarea`<sup>p508</sup> element has a **dirty value flag**, which must be initially set to false, and must be set to true whenever the user interacts with the control in a way that changes the [raw value](#)<sup>p509</sup>.

When the `textarea`<sup>p508</sup> element's `textContent`<sup>p51</sup> IDL attribute changes value, if the element's **dirty value flag**<sup>p510</sup> is false, then the element's [raw value](#)<sup>p509</sup> must be set to the value of the element's `textContent`<sup>p51</sup> IDL attribute.

The [reset algorithm](#)<sup>p567</sup> for `textarea`<sup>p508</sup> elements is to set the element's [raw value](#)<sup>p509</sup> to the value of the element's `textContent`<sup>p51</sup> IDL Spec bugs: [27504](#)

When a `textarea`<sup>p508</sup> element is popped off the [stack of open elements](#)<sup>p962</sup> of an [HTML parser](#)<sup>p952</sup> or [XML parser](#)<sup>p1054</sup>, then the user agent must invoke the element's [reset algorithm](#)<sup>p567</sup>.

If the element is [mutable](#)<sup>p527</sup>, the user agent should allow the user to change the writing direction of the element, setting it either to a left-to-right writing direction or a right-to-left writing direction. If the user does so, the user agent must then run the following steps:

1. Set the element's `dir`<sup>b125</sup> attribute to "`ltr`<sup>p125</sup>" if the user selected a left-to-right writing direction, and "`rtl`<sup>p125</sup>" if the user selected a right-to-left writing direction.
2. [Queue a task](#)<sup>p835</sup> to [fire a simple event](#)<sup>p846</sup> that bubbles named `input`<sup>p1144</sup> at the `textarea`<sup>p508</sup> element.

The `cols` attribute specifies the expected maximum number of characters per line. If the `cols`<sup>p510</sup> attribute is specified, its value must be a [valid non-negative integer](#)<sup>p61</sup> greater than zero. If applying the [rules for parsing non-negative integers](#)<sup>p61</sup> to the attribute's value results in a number greater than zero, then the element's **character width** is that value; otherwise, it is 20.

The user agent may use the `textarea`<sup>p508</sup> element's **character width**<sup>p510</sup> as a hint to the user as to how many characters the server prefers per line (e.g. for visual user agents by making the width of the control be that many characters). In visual renderings, the user agent should wrap the user's input in the rendering so that each line is no wider than this number of characters.

The `rows` attribute specifies the number of lines to show. If the `rows`<sup>p510</sup> attribute is specified, its value must be a [valid non-negative integer](#)<sup>p61</sup> greater than zero. If applying the [rules for parsing non-negative integers](#)<sup>p61</sup> to the attribute's value results in a number greater than zero, then the element's **character height** is that value; otherwise, it is 2.

Visual user agents should set the height of the control to the number of lines given by [character height](#)<sup>p510</sup>.

The `wrap` attribute is an [enumerated attribute](#)<sup>p60</sup> with two keywords and states: the **soft** keyword which maps to the [Soft](#)<sup>p510</sup> state, and the **hard** keyword which maps to the [Hard](#)<sup>p510</sup> state. The [missing value default](#)<sup>p60</sup> is the [Soft](#)<sup>p510</sup> state.

The **Soft** state indicates that the text in the `textarea`<sup>p508</sup> is not to be wrapped when it is submitted (though it can still be wrapped in the rendering).

The **Hard** state indicates that the text in the `textarea`<sup>p508</sup> is to have newlines added by the user agent so that the text is wrapped when it is submitted.

If the element's `wrap`<sup>p510</sup> attribute is in the [Hard](#)<sup>p510</sup> state, the `cols`<sup>p510</sup> attribute must be specified.

For historical reasons, the element's value is normalised in three different ways for three different purposes. The [raw value](#)<sup>p509</sup> is the value as it was originally set. It is not normalized. The [API value](#)<sup>p511</sup> is the value used in the `value`<sup>p512</sup> IDL attribute. It is normalised so that line breaks use U+000A LINE FEED (LF) characters. Finally, there is the [value](#)<sup>p527</sup>, as used in form submission and other processing models in this specification. It is normalised so that line breaks use U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF) character pairs, and in addition, if necessary given the element's `wrap`<sup>p510</sup> attribute, additional line breaks are inserted to wrap the text at the given width.

The element's **API value** is defined to be the element's [raw value<sup>p509</sup>](#) with the following transformation applied:

1. Replace every U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF) character pair from the [raw value<sup>p509</sup>](#) with a single U+000A LINE FEED (LF) character.
2. Replace every remaining U+000D CARRIAGE RETURN character from the [raw value<sup>p509</sup>](#) with a single U+000A LINE FEED (LF) character.

The element's [value<sup>b527</sup>](#) is defined to be the element's [raw value<sup>p509</sup>](#) with the [textarea wrapping transformation<sup>p511</sup>](#) applied. The **textarea wrapping transformation** is the following algorithm, as applied to a string:

1. Replace every occurrence of a U+000D CARRIAGE RETURN (CR) character not followed by a U+000A LINE FEED (LF) character, and every occurrence of a U+000A LINE FEED (LF) character not preceded by a U+000D CARRIAGE RETURN (CR) character, by a two-character string consisting of a U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF) character pair.
2. If the element's [wrap<sup>p510</sup>](#) attribute is in the [Hard<sup>p510</sup>](#) state, insert U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF) character pairs into the string using a UA-defined algorithm so that each line has no more than [character width<sup>p510</sup>](#) characters. For the purposes of this requirement, lines are delimited by the start of the string, the end of the string, and U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF) character pairs.

The [maxlength](#) attribute is a [form control maxlength attribute<sup>p529</sup>](#) controlled by the [textarea<sup>p508</sup>](#) element's [dirty value flag<sup>p510</sup>](#).

If the [textarea<sup>p508</sup>](#) element has a [maximum allowed value length<sup>p529</sup>](#), then the element's children must be such that the [code-unit length<sup>p44</sup>](#) of the value of the element's [textContent<sup>p51</sup>](#) IDL attribute with the [textarea wrapping transformation<sup>p511</sup>](#) applied is equal to or less than the element's [maximum allowed value length<sup>p529</sup>](#).

The [minlength](#) attribute is a [form control minlength attribute<sup>p530</sup>](#) controlled by the [textarea<sup>p508</sup>](#) element's [dirty value flag<sup>p510</sup>](#).

The [required](#) attribute is a [boolean attribute<sup>p59</sup>](#). When specified, the user will be required to enter a value before submitting the form.

**Constraint validation:** If the element has its [required<sup>p511</sup>](#) attribute specified, and the element is [mutable<sup>b527</sup>](#), and the element's [value<sup>b527</sup>](#) is the empty string, then the element is [suffering from being missing<sup>b553</sup>](#).

The [placeholder](#) attribute represents a *short* hint (a word or short phrase) intended to aid the user with data entry when the control has no value. A hint could be a sample value or a brief description of the expected format.

The [placeholder<sup>p511</sup>](#) attribute should not be used as an alternative to a [label<sup>p451</sup>](#). For a longer hint or other advisory text, the [title<sup>p122</sup>](#) attribute is more appropriate.

**Note** These mechanisms are very similar but subtly different: the hint given by the control's [label<sup>p451</sup>](#) is shown at all times; the short hint given in the [placeholder<sup>p511</sup>](#) attribute is shown before the user enters a value; and the hint in the [title<sup>p122</sup>](#) attribute is shown when the user requests further help.

User agents should present this hint to the user when the element's [value<sup>b527</sup>](#) is the empty string and the control is not [focused<sup>b728</sup>](#) (e.g. by displaying it inside a blank unfocused control). All U+000D CARRIAGE RETURN U+000A LINE FEED character pairs (CRLF) in the hint, as well as all other U+000D CARRIAGE RETURN (CR) and U+000A LINE FEED (LF) characters in the hint, must be treated as line breaks when rendering the hint.

The [name<sup>p529</sup>](#) attribute represents the element's name. The [dirname<sup>b529</sup>](#) attribute controls how the element's [directionality<sup>p125</sup>](#) is submitted. The [disabled<sup>p530</sup>](#) attribute is used to make the control non-interactive and to prevent its value from being submitted. The [form<sup>p527</sup>](#) attribute is used to explicitly associate the [textarea<sup>p508</sup>](#) element with its [form owner<sup>p527</sup>](#). The [autofocus<sup>p533</sup>](#) attribute controls focus. The [inputmode<sup>p534</sup>](#) attribute controls the user interface's input modality for the control. The [autocomplete<sup>p535</sup>](#) attribute controls how the user agent provides autofill behaviour.

**Note**

`textarea . typep512`

Returns the string "textarea".

`textarea . valuep512`

Returns the current value of the element.

Can be set, to change the value.

The `cols`, `placeholder`, `required`, `rows`, and `wrap` attributes must `reflectb88` the respective content attributes of the same name. The `colsp512` and `rowsp512` attributes are `limited to only non-negative numbers greater than zerob89`. The `colsp512` attribute's default value is 20. The `rowsp512` attribute's default value is 2. The `dirName` IDL attribute must `reflectb88` the `dirnamep529` content attribute. The `inputMode` IDL attribute must `reflectb88` the `inputmodep534` content attribute, `limited to only known valuesb89`. The `maxLength` IDL attribute must `reflectb88` the `maxlengthp511` content attribute, `limited to only non-negative numbersb89`. The `minLength` IDL attribute must `reflectb88` the `minlengthp511` content attribute, `limited to only non-negative numbersb89`. The `readOnly` IDL attribute must `reflectb88` the `readonlyp509` content attribute.

The `type` IDL attribute must return the value "textarea".

The `defaultValue` IDL attribute must act like the element's `textContentp51` IDL attribute.

The `value` attribute must, on getting, return the element's `API valuep511`; on setting, it must set the element's `raw valuep509` to the new value, set the element's `dirty value flagp510` to true, and should then move the text entry cursor position to the end of the text field, unselecting any selected text and resetting the selection direction to `none`.

The `textLength` IDL attribute must return the `code-unit lengthp44` of the element's `API valuep511`.

The `willValidatep555`, `validityb556`, and `validationMessagep557` IDL attributes, and the `checkValidity()p556`, `reportValidity()p557`, and `setCustomValidity()p555` methods, are part of the `constraint validation APIp554`. The `labelsp452` IDL attribute provides a list of the element's `labelp451`s. The `select()p551`, `selectionStartp551`, `selectionEndp551`, `selectionDirectionp551`, `setRangeText()p551`, and `setSelectionRange()p551` methods and IDL attributes expose the element's text selection. The `autofocusp533`, `disabledp530`, `formp529`, and `namep529` IDL attributes are part of the element's forms API.

### Example

Here is an example of a `textareap508` being used for unrestricted free-form text input in a form:

```
<p>If you have any comments, please let us know: <textarea cols=80 name=comments></textarea></p>
```

To specify a maximum length for the comments, one can use the `maxlengthp511` attribute:

```
<p>If you have any short comments, please let us know: <textarea cols=80 name=comments
maxlength=200></textarea></p>
```

To give a default value, text can be included inside the element:

```
<p>If you have any comments, please let us know: <textarea cols=80 name=comments>You
rock!</textarea></p>
```

You can also give a minimum length. Here, a letter needs to be filled out by the user; a template (which is shorter than the minimum length) is provided, but is insufficient to submit the form:

```
<textarea required minlength="500">Dear Madam Speaker,
```

```
Regarding your letter dated ...
```

```
...
```

```
Yours Sincerely,
```

```
...</textarea>
```

A placeholder can be given as well, to suggest the basic form to the user, without providing an explicit template:

```
<textarea placeholder="Dear Francine,
```

```
They closed the parks this week, so we won't be able to
meet your there. Should we just have dinner?
```

```
Love,
Daddy"></textare>
```

To have the browser submit [the directionality](#)<sup>p125</sup> of the element along with the value, the [dirname](#)<sup>p529</sup> attribute can be specified:

```
<p>If you have any comments, please let us know (you may use either English or Hebrew for your
comments):
<textarea cols=80 name=comments dirname=comments.dir></textarea></p>
```

#### 4.10.12 The `keygen` element

Categories<sup>p113</sup>:

[Flow content](#)<sup>p115</sup>.  
[Phrasing content](#)<sup>p116</sup>.  
[Interactive content](#)<sup>p116</sup>.  
[Listed](#)<sup>p446</sup>, [labelable](#)<sup>p447</sup>, [submittable](#)<sup>p447</sup>, [resettable](#)<sup>p447</sup>, and [reassociateable](#)<sup>p447</sup> [form-associated element](#)<sup>p446</sup>.  
[Palpable content](#)<sup>p117</sup>.

Contexts in which this element can be used<sup>p113</sup>:

Where [phrasing content](#)<sup>p116</sup> is expected.

Content model<sup>p113</sup>:

[Nothing](#)<sup>p114</sup>.

Tag omission in text/html<sup>p113</sup>:

No end tag<sup>p944</sup>.

Content attributes<sup>p113</sup>:

[Global attributes](#)<sup>p120</sup>  
[autofocus](#)<sup>p533</sup> — Automatically focus the form control when the page is loaded  
[challenge](#)<sup>p514</sup> — String to package with the generated and signed public key  
[disabled](#)<sup>p530</sup> — Whether the form control is disabled  
[form](#)<sup>p527</sup> — Associates the control with a [form](#)<sup>p447</sup> element  
[keytype](#)<sup>p514</sup> — The type of cryptographic key to generate  
[name](#)<sup>p529</sup> — Name of form control to use for [form submission](#)<sup>p557</sup> and in the [form.elements](#)<sup>p449</sup> API

DOM interface<sup>p113</sup>:

```
IDL interface HTMLKeygenElement : HTMLElement {
 attribute boolean autofocus;
 attribute DOMString challenge;
 attribute boolean disabled;
 readonly attribute HTMLFormElement? form;
 attribute DOMString keytype;
 attribute DOMString name;

 readonly attribute DOMString type;

 readonly attribute boolean willValidate;
 readonly attribute ValidityState validity;
 readonly attribute DOMString validationMessage;
 boolean checkValidity();
 boolean reportValidity();
 void setCustomValidity(DOMString error);

 readonly attribute NodeList labels;
};
```

The [keygen](#)<sup>p513</sup> element [represents](#)<sup>p111</sup> a key pair generator control. When the control's form is submitted, the private key is stored in the local keystore, and the public key is packaged and sent to the server.

The [challenge](#) attribute may be specified. Its value will be packaged with the submitted key.

The [keytype](#) attribute is an [enumerated attribute](#)<sup>p60</sup>. The following table lists the keywords and states for the attribute — the keywords in the left column map to the states listed in the cell in the second column on the same row as the keyword. User agents are not required to support these values, and must only recognise values whose corresponding algorithms they support.

Keyword	State
rsa	RSA

The [invalid value default](#)<sup>p60</sup> state is the *unknown* state. The [missing value default](#)<sup>p60</sup> state is the RSA state, if it is supported, or the *unknown* state otherwise.

**Note** *This specification does not specify what key types user agents are to support — it is possible for a user agent to not support any key types at all.*

The user agent may expose a user interface for each [keygen](#)<sup>p513</sup> element to allow the user to configure settings of the element's key pair generator, e.g. the key length.

The [reset algorithm](#)<sup>p567</sup> for [keygen](#)<sup>p513</sup> elements is to set these various configuration settings back to their defaults.

The element's [value](#)<sup>p527</sup> is the string returned from the following algorithm:

1. Use the appropriate step from the following list:

↪ If the [keytype](#)<sup>p514</sup> attribute is in the RSA state

Generate an RSA key pair using the settings given by the user, if appropriate, using the `md5WithRSAEncryption` RSA signature algorithm (the signature algorithm with MD5 and the RSA encryption algorithm) referenced in section 2.2.1 ("RSA Signature Algorithm") of RFC 3279, and defined in RFC 3447. [\[RFC3279\]](#)<sup>p1152</sup> [\[RFC3447\]](#)<sup>p1152</sup>

↪ Otherwise, the [keytype](#)<sup>p514</sup> attribute is in the unknown state

The given key type is not supported. Return the empty string and abort this algorithm.

Let *private key* be the generated private key.

Let *public key* be the generated public key.

Let *signature algorithm* be the selected signature algorithm.

2. If the element has a [challenge](#)<sup>p514</sup> attribute, then let *challenge* be that attribute's value. Otherwise, let *challenge* be the empty string.
3. Let *algorithm* be an ASN.1 `AlgorithmIdentifier` structure as defined by RFC 5280, with the `algorithm` field giving the ASN.1 OID used to identify *signature algorithm*, using the OIDs defined in section 2.2 ("Signature Algorithms") of RFC 3279, and the `parameters` field set up as required by RFC 3279 for `AlgorithmIdentifier` structures for that algorithm. [\[X690\]](#)<sup>p1154</sup> [\[RFC5280\]](#)<sup>p1153</sup> [\[RFC3279\]](#)<sup>p1152</sup>
4. Let *spki* be an ASN.1 `SubjectPublicKeyInfo` structure as defined by RFC 5280, with the `algorithm` field set to the *algorithm* structure from the previous step, and the `subjectPublicKey` field set to the BIT STRING value resulting from ASN.1 DER encoding the *public key*. [\[X690\]](#)<sup>p1154</sup> [\[RFC5280\]](#)<sup>p1153</sup>
5. Let *publicKeyAndChallenge* be an ASN.1 [PublicKeyAndChallenge](#)<sup>p515</sup> structure as defined below, with the `spki` field set to the *spki* structure from the previous step, and the `challenge` field set to the string *challenge* obtained earlier. [\[X690\]](#)<sup>p1154</sup>
6. Let *signature* be the BIT STRING value resulting from ASN.1 DER encoding the signature generated by applying the *signature algorithm* to the byte string obtained by ASN.1 DER encoding the *publicKeyAndChallenge* structure, using *private key* as the signing key. [\[X690\]](#)<sup>p1154</sup>
7. Let *signedPublicKeyAndChallenge* be an ASN.1 [SignedPublicKeyAndChallenge](#)<sup>p515</sup> structure as defined below, with the `publicKeyAndChallenge` field set to the *publicKeyAndChallenge* structure, the `signatureAlgorithm` field set to the *algorithm* structure, and the `signature` field set to the BIT STRING *signature* from the previous step. [\[X690\]](#)<sup>p1154</sup>

8. Return the result of base64 encoding the result of ASN.1 DER encoding the *signedPublicKeyAndChallenge* structure. [RFC4648]<sup>p1153</sup>  
[\[X690\]<sup>p1154</sup>](#)

The data objects used by the above algorithm are defined as follows. These definitions use the same "ASN.1-like" syntax defined by RFC 5280.  
[\[RFC5280\]<sup>p1153</sup>](#)

ASN

```

PublicKeyAndChallenge ::= SEQUENCE {
 spki SubjectPublicKeyInfo,
 challenge IA5STRING
}

SignedPublicKeyAndChallenge ::= SEQUENCE {
 publicKeyAndChallenge PublicKeyAndChallenge,
 signatureAlgorithm AlgorithmIdentifier,
 signature BIT STRING
}

```

**Constraint validation:** The [keygen](#)<sup>p513</sup> element is [barred from constraint validation](#)<sup>p553</sup>.

The [form](#)<sup>p527</sup> attribute is used to explicitly associate the [keygen](#)<sup>p513</sup> element with its [form owner](#)<sup>p527</sup>. The [name](#)<sup>p529</sup> attribute represents the element's name. The [disabled](#)<sup>p530</sup> attribute is used to make the control non-interactive and to prevent its value from being submitted. The [autofocus](#)<sup>p533</sup> attribute controls focus.

Note

[keygen . type](#)<sup>p515</sup>

Returns the string "keygen".

The [challenge](#) IDL attribute must [reflect](#)<sup>p88</sup> the content attribute of the same name.

The [keytype](#) IDL attribute must [reflect](#)<sup>p88</sup> the content attribute of the same name, [limited to only known values](#)<sup>p89</sup>.

The [type](#) IDL attribute must return the value "keygen".

The [willValidate](#)<sup>p555</sup>, [validity](#)<sup>p556</sup>, and [validationMessage](#)<sup>p557</sup> IDL attributes, and the [checkValidity\(\)](#)<sup>p556</sup>, [reportValidity\(\)](#)<sup>p557</sup>, and [setCustomValidity\(\)](#)<sup>p555</sup> methods, are part of the [constraint validation API](#)<sup>p554</sup>. The [labels](#)<sup>p452</sup> IDL attribute provides a list of the element's [label](#)<sup>p451</sup>s. The [autofocus](#)<sup>p533</sup>, [disabled](#)<sup>p530</sup>, [form](#)<sup>p529</sup>, and [name](#)<sup>p529</sup> IDL attributes are part of the element's forms API.

Note

*This specification does not specify how the private key generated is to be used. It is expected that after receiving the [SignedPublicKeyAndChallenge](#)<sup>p515</sup> (SPKAC) structure, the server will generate a client certificate and offer it back to the user for download; this certificate, once downloaded and stored in the key store along with the private key, can then be used to authenticate to services that use TLS and certificate authentication. For more information, see e.g. [this MDN article](#).*

Example

To generate a key pair, add the private key to the user's key store, and submit the public key to the server, markup such as the following can be used:

```

<form action="processkey.cgi" method="post" enctype="multipart/form-data">
 <p><keygen name="key"></p>
 <p><input type=submit value="Submit key..."></p>
</form>

```

The server will then receive a form submission with a packaged RSA public key as the value of "key". This can then be used for various purposes, such as generating a client certificate, as mentioned above.

#### 4.10.13 The `output` element

Categories<sup>p113</sup>:

[Flow content<sup>p115</sup>](#).  
[Phrasing content<sup>p116</sup>](#).  
[Listed<sup>p446</sup>](#), [labelable<sup>p447</sup>](#), [resettable<sup>p447</sup>](#), and [reassociateable<sup>p447</sup>](#) [form-associated element<sup>p446</sup>](#).  
[Palpable content<sup>p117</sup>](#).

Contexts in which this element can be used<sup>p113</sup>:

Where [phrasing content<sup>p116</sup>](#) is expected.

Content model<sup>p113</sup>:

[Phrasing content<sup>p116</sup>](#).

Tag omission in `text/html`<sup>p113</sup>:

Neither tag is omitable.

Content attributes<sup>p113</sup>:

[Global attributes<sup>p120</sup>](#)

[for<sup>p516</sup>](#) — Specifies controls from which the output was calculated  
[form<sup>p527</sup>](#) — Associates the control with a [form<sup>p447</sup>](#) element  
[name<sup>p529</sup>](#) — Name of form control to use in the [form.elements<sup>p449</sup>](#) API

DOM interface<sup>p113</sup>:

```
IDL interface HTMLOutputElement : HTMLElement {
 [PutForwards=value] readonly attribute DOMSettableTokenList htmlFor;
 readonly attribute HTMLFormElement? form;
 attribute DOMString name;

 readonly attribute DOMString type;
 attribute DOMString defaultValue;
 attribute DOMString value;

 readonly attribute boolean willValidate;
 readonly attribute ValidityState validity;
 readonly attribute DOMString validationMessage;
 boolean checkValidity();
 boolean reportValidity();
 void setCustomValidity(DOMString error);

 readonly attribute NodeList labels;
};
```

The [output<sup>p516</sup>](#) element [represents<sup>p111</sup>](#) the result of a calculation performed by the application, or the result of a user action.

**Note** This element can be contrasted with the [samp<sup>p233</sup>](#) element, which is the appropriate element for quoting the output of other programs run previously.

The [for](#) content attribute allows an explicit relationship to be made between the result of a calculation and the elements that represent the values that went into the calculation or that otherwise influenced the calculation. The [for<sup>p516</sup>](#) attribute, if specified, must contain a string consisting of an [unordered set of unique space-separated tokens<sup>p80</sup>](#) that are [case-sensitive<sup>p58</sup>](#), each of which must have the value of an [ID<sup>p51</sup>](#) of an element in the same [Document<sup>p102</sup>](#).

The [form<sup>p527</sup>](#) attribute is used to explicitly associate the [output<sup>p516</sup>](#) element with its [form owner<sup>p527</sup>](#). The [name<sup>p529</sup>](#) attribute represents the element's name. The [output<sup>p516</sup>](#) element is associated with a form so that it can be easily referenced from the event handlers of form controls; the element's value itself is not submitted when the form is submitted.

The element has a **value mode flag** which is either [value<sup>p517</sup>](#) or [default<sup>p517</sup>](#). Initially, the [value mode flag<sup>p516</sup>](#) must be set to [default<sup>p517</sup>](#).

The element also has a **default value**. Initially, the [default value<sup>p516</sup>](#) must be the empty string.

When the [value mode flag](#)<sup>p516</sup> is in mode **default**, the contents of the element represent both the value of the element and its [default value](#)<sup>p516</sup>. When the [value mode flag](#)<sup>p516</sup> is in mode **value**, the contents of the element represent the value of the element only, and the [default value](#)<sup>p516</sup> is only accessible using the [defaultValue](#)<sup>p517</sup> IDL attribute.

Whenever the element's descendants are changed in any way, if the [value mode flag](#)<sup>p516</sup> is in mode [default](#)<sup>p517</sup>, the element's [default value](#)<sup>p516</sup> must be set to the value of the element's [textContent](#)<sup>p51</sup> IDL attribute.

The [reset algorithm](#)<sup>p567</sup> for [output](#)<sup>p516</sup> elements is to set the element's [value mode flag](#)<sup>p516</sup> to [default](#)<sup>p517</sup> and then to set the element's [textContent](#)<sup>p51</sup> IDL attribute to the value of the element's [default value](#)<sup>p516</sup> (thus replacing the element's child nodes).

#### Note

**output.value**<sup>p517</sup> [= *value*]

Returns the element's current value.

Can be set, to change the value.

**output.defaultValue**<sup>p517</sup> [= *value*]

Returns the element's current default value.

Can be set, to change the default value.

**output.type**<sup>p517</sup>

Returns the string "output".

The **value** IDL attribute must act like the element's [textContent](#)<sup>p51</sup> IDL attribute, except that on setting, in addition, before the child nodes are changed, the element's [value mode flag](#)<sup>p516</sup> must be set to [value](#)<sup>p517</sup>.

The [defaultValue](#) IDL attribute, on getting, must return the element's [default value](#)<sup>p516</sup>. On setting, the attribute must set the element's [default value](#)<sup>p516</sup>, and, if the element's [value mode flag](#)<sup>p516</sup> is in the mode [default](#)<sup>p517</sup>, set the element's [textContent](#)<sup>p51</sup> IDL attribute as well.

The **type** attribute must return the string "output".

The **htmlFor** IDL attribute must [reflect](#)<sup>p88</sup> the [for](#)<sup>p516</sup> content attribute.

The [willValidate](#)<sup>p555</sup>, [validity](#)<sup>p556</sup>, and [validationMessage](#)<sup>p557</sup> IDL attributes, and the [checkValidity\(\)](#)<sup>p556</sup>, [reportValidity\(\)](#)<sup>p557</sup>, and [setCustomValidity\(\)](#)<sup>p555</sup> methods, are part of the [constraint validation API](#)<sup>p554</sup>. The [labels](#)<sup>p452</sup> IDL attribute provides a list of the element's [label](#)<sup>p451</sup>s. The [form](#)<sup>p529</sup> and [name](#)<sup>p529</sup> IDL attributes are part of the element's forms API.

#### Example

A simple calculator could use [output](#)<sup>p516</sup> for its display of calculated results:

```
<form onsubmit="return false" oninput="o.value = a.valueAsNumber + b.valueAsNumber">
 <input name=a type=number step=any> +
 <input name=b type=number step=any> =
 <output name=o for="a b"></output>
</form>
```

#### Example

In this example, an [output](#)<sup>p516</sup> element is used to report the results of a calculation performed by a remote server, as they come in:

```
<output id="result"></output>
<script>
var primeSource = new WebSocket('ws://primes.example.net/');
primeSource.onmessage = function (event) {
 document.getElementById('result').value = event.data;
}
</script>
```

#### 4.10.14 The `progress` element

Spec bugs:	<a href="#">18093</a>
Support:	
Chrome	8+
IE (limited)	10+
Chrome for Android	40+
Firefox	16+
iOS Safari (limited)	7.0-7.1+
Android Browser	4.4+
UC Browser for Android	9.9+
Opera Mini	None
Safari	6+
Opera	11+
IE Mobile (limited)	10+
Firefox for Android	33+

Source: [caniuse.com](#)

##### Categories<sup>p113</sup>:

- [Flow content<sup>p115</sup>](#).
- [Phrasing content<sup>p116</sup>](#).
- [Labelable element<sup>p447</sup>](#).
- [Palpable content<sup>p117</sup>](#).

##### Contexts in which this element can be used<sup>p113</sup>:

Where [phrasing content<sup>p116</sup>](#) is expected.

##### Content model<sup>p113</sup>:

[Phrasing content<sup>p116</sup>](#), but there must be no [progress<sup>p518</sup>](#) element descendants.

##### Tag omission in text/html<sup>p113</sup>:

Neither tag is omitable.

##### Content attributes<sup>p113</sup>:

###### [Global attributes<sup>p120</sup>](#)

- [value<sup>p518</sup>](#) — Current value of the element
- [max<sup>p518</sup>](#) — Upper bound of range

##### DOM interface<sup>p113</sup>:

```
IDL interface HTMLProgressElement : HTMLElement {
 attribute double value;
 attribute double max;
 readonly attribute double position;
 readonly attribute NodeList labels;
};
```

The [progress<sup>p518</sup>](#) element [represents<sup>p111</sup>](#) the completion progress of a task. The progress is either indeterminate, indicating that progress is being made but that it is not clear how much more work remains to be done before the task is complete (e.g. because the task is waiting for a remote host to respond), or the progress is a number in the range zero to a maximum, giving the fraction of work that has so far been completed.

There are two attributes that determine the current task completion represented by the element. The [value](#) attribute specifies how much of the task has been completed, and the [max](#) attribute specifies how much work the task requires in total. The units are arbitrary and not specified.

**Note** To make a determinate progress bar, add a [value<sup>p518</sup>](#) attribute with the current progress (either a number from 0.0 to 1.0, or, if the [max<sup>p518</sup>](#) attribute is specified, a number from 0 to the value of the [max<sup>p518</sup>](#) attribute). To make an indeterminate progress bar, remove the [value<sup>p518</sup>](#) attribute.

Authors are encouraged to also include the current value and the maximum value inline as text inside the element, so that the progress is made available to users of legacy user agents.

##### Example

Here is a snippet of a Web application that shows the progress of some automated task:

```
<section>
 <h2>Task Progress</h2>
 <p>Progress: <progress id="p" max=100>0%</progress></p>
 <script>
 var progressBar = document.getElementById('p');
 function updateProgress(newValue) {
 progressBar.value = newValue;
 progressBar.getElementsByTagName('span')[0].textContent = newValue;
 }
 </script>
</section>
```

(The `updateProgress()` method in this example would be called by some other code on the page to update the actual progress bar as the task progressed.)

The `value`<sup>p518</sup> and `max`<sup>p518</sup> attributes, when present, must have values that are [valid floating-point numbers](#)<sup>p61</sup>. The `value`<sup>p518</sup> attribute, if present, must have a value equal to or greater than zero, and less than or equal to the value of the `max`<sup>p518</sup> attribute, if present, or 1.0, otherwise. The `max`<sup>p518</sup> attribute, if present, must have a value greater than zero.

**Note** *The `progress`<sup>p518</sup> element is the wrong element to use for something that is just a gauge, as opposed to task progress. For instance, indicating disk space usage using `progress`<sup>p518</sup> would be inappropriate. Instead, the `meter`<sup>p519</sup> element is available for such use cases.*

**User agent requirements:** If the `value`<sup>p518</sup> attribute is omitted, then the progress bar is an indeterminate progress bar. Otherwise, it is a determinate progress bar.

If the progress bar is a determinate progress bar and the element has a `max`<sup>p518</sup> attribute, the user agent must parse the `max`<sup>p518</sup> attribute's value according to the [rules for parsing floating-point number values](#)<sup>p62</sup>. If this does not result in an error, and if the parsed value is greater than zero, then the **maximum value** of the progress bar is that value. Otherwise, if the element has no `max`<sup>p518</sup> attribute, or if it has one but parsing it resulted in an error, or if the parsed value was less than or equal to zero, then the **maximum value**<sup>p519</sup> of the progress bar is 1.0.

If the progress bar is a determinate progress bar, user agents must parse the `value`<sup>p518</sup> attribute's value according to the [rules for parsing floating-point number values](#)<sup>p62</sup>. If this does not result in an error, and if the parsed value is less than the **maximum value**<sup>p519</sup> and greater than zero, then the **current value** of the progress bar is that parsed value. Otherwise, if the parsed value was greater than or equal to the **maximum value**<sup>p519</sup>, then the **current value**<sup>p519</sup> of the progress bar is the **maximum value**<sup>p519</sup> of the progress bar. Otherwise, if parsing the `value`<sup>p518</sup> attribute's value resulted in an error, or a number less than or equal to zero, then the **current value**<sup>p519</sup> of the progress bar is zero.

**UA requirements for showing the progress bar:** When representing a `progress`<sup>p518</sup> element to the user, the UA should indicate whether it is a determinate or indeterminate progress bar, and in the former case, should indicate the relative position of the **current value**<sup>p519</sup> relative to the **maximum value**<sup>p519</sup>.

**Note**

`progress . position`<sup>p519</sup>

For a determinate progress bar (one with known current and maximum values), returns the result of dividing the current value by the maximum value.

For an indeterminate progress bar, returns -1.

If the progress bar is an indeterminate progress bar, then the `position` IDL attribute must return -1. Otherwise, it must return the result of dividing the **current value**<sup>p519</sup> by the **maximum value**<sup>p519</sup>.

If the progress bar is an indeterminate progress bar, then the `value` IDL attribute, on getting, must return 0. Otherwise, it must return the **current value**<sup>p519</sup>. On setting, the given value must be converted to the [best representation of the number as a floating-point number](#)<sup>p62</sup> and then the `value`<sup>p519</sup> content attribute must be set to that string.

**Note** *Setting the `value`<sup>p519</sup> IDL attribute to itself when the corresponding content attribute is absent would change the progress bar from an indeterminate progress bar to a determinate progress bar with no progress.*

The `max` IDL attribute must [reflect](#)<sup>p88</sup> the content attribute of the same name, [limited to numbers greater than zero](#)<sup>p89</sup>. The default value for `max`<sup>p519</sup> is 1.0.

The `labels`<sup>p452</sup> IDL attribute provides a list of the element's `label`<sup>p451</sup>s.

#### 4.10.15 The `meter` element

**Categories**<sup>p113</sup>:

[Flow content](#)<sup>p115</sup>.  
[Phrasing content](#)<sup>p116</sup>.  
[Labelable element](#)<sup>p447</sup>.  
[Palpable content](#)<sup>p117</sup>.

**Contexts in which this element can be used**<sup>p113</sup>:

Where [phrasing content](#)<sup>p116</sup> is expected.

### Content model<sup>p113</sup>:

Phrasing content<sup>p116</sup>, but there must be no meter<sup>p519</sup> element descendants.

### Tag omission in text/html<sup>p113</sup>:

Neither tag is omissionable.

### Content attributes<sup>p113</sup>:

#### Global attributes<sup>p120</sup>

value<sup>p520</sup> — Current value of the element  
min<sup>p520</sup> — Lower bound of range  
max<sup>p520</sup> — Upper bound of range  
low<sup>p520</sup> — High limit of low range  
high<sup>p520</sup> — Low limit of high range  
optimum<sup>p520</sup> — Optimum value in gauge

### DOM interface<sup>p113</sup>:

```
IDL interface HTMLMeterElement : HTMLElement {
 attribute double value;
 attribute double min;
 attribute double max;
 attribute double low;
 attribute double high;
 attribute double optimum;
 readonly attribute NodeList labels;
};
```

The meter<sup>p519</sup> element represents<sup>p111</sup> a scalar measurement within a known range, or a fractional value; for example disk usage, the relevance of a query result, or the fraction of a voting population to have selected a particular candidate.

This is also known as a gauge.

**Note** The meter<sup>p519</sup> element should not be used to indicate progress (as in a progress bar). For that role, HTML provides a separate progress<sup>p518</sup> element.

**Note** The meter<sup>p519</sup> element also does not represent a scalar value of arbitrary range — for example, it would be wrong to use this to report a weight, or height, unless there is a known maximum value.

There are six attributes that determine the semantics of the gauge represented by the element.

The min attribute specifies the lower bound of the range, and the max attribute specifies the upper bound. The value attribute specifies the value to have the gauge indicate as the "measured" value.

The other three attributes can be used to segment the gauge's range into "low", "medium", and "high" parts, and to indicate which part of the gauge is the "optimum" part. The low attribute specifies the range that is considered to be the "low" part, and the high attribute specifies the range that is considered to be the "high" part. The optimum attribute gives the position that is "optimum"; if that is higher than the "high" value then this indicates that the higher the value, the better; if it's lower than the "low" mark then it indicates that lower values are better, and naturally if it is in between then it indicates that neither high nor low values are good.

**Authoring requirements:** The value<sup>p520</sup> attribute must be specified. The value<sup>p520</sup>, min<sup>p520</sup>, low<sup>p520</sup>, high<sup>p520</sup>, max<sup>p520</sup>, and optimum<sup>p520</sup> attributes, when present, must have values that are valid floating-point numbers<sup>p61</sup>.

In addition, the attributes' values are further constrained:

Let value be the value<sup>p520</sup> attribute's number.

If the min<sup>p520</sup> attribute is specified, then let minimum be that attribute's value; otherwise, let it be zero.

If the max<sup>p520</sup> attribute is specified, then let maximum be that attribute's value; otherwise, let it be 1.0.

The following inequalities must hold, as applicable:

- $\text{minimum} \leq \text{value} \leq \text{maximum}$
- $\text{minimum} \leq \text{low}^{\text{p520}} \leq \text{maximum}$  (if  $\text{low}^{\text{p520}}$  is specified)
- $\text{minimum} \leq \text{high}^{\text{p520}} \leq \text{maximum}$  (if  $\text{high}^{\text{p520}}$  is specified)
- $\text{minimum} \leq \text{optimum}^{\text{p520}} \leq \text{maximum}$  (if  $\text{optimum}^{\text{p520}}$  is specified)
- $\text{low}^{\text{p520}} \leq \text{high}^{\text{p520}}$  (if both  $\text{low}^{\text{p520}}$  and  $\text{high}^{\text{p520}}$  are specified)

**Note** If no minimum or maximum is specified, then the range is assumed to be 0..1, and the value thus has to be within that range.

Authors are encouraged to include a textual representation of the gauge's state in the element's contents, for users of user agents that do not support the `meter`<sup>p519</sup> element.

When used with `microdata`<sup>p683</sup>, the `meter`<sup>p519</sup> element's `value`<sup>p520</sup> attribute provides the element's machine-readable value.

### Example

The following examples show three gauges that would all be three-quarters full:

```
Storage space usage: <meter value=6 max=8>6 blocks used (out of 8 total)</meter>
Voter turnout: <meter value=0.75></meter>
Tickets sold: <meter min="0" max="100" value="75"></meter>
```

The following example is incorrect use of the element, because it doesn't give a range (and since the default maximum is 1, both of the gauges would end up looking maxed out):

```
<p>The grapefruit pie had a radius of <meter value=12>12cm</meter>
and a height of <meter value=2>2cm</meter>.<!-- BAD! --></pre>
```

Instead, one would either not include the `meter` element, or use the `meter` element with a defined range to give the dimensions in context compared to other pies:

```
<p>The grapefruit pie had a radius of 12cm and a height of
2cm.</p>
<dl>
 <dt>Radius: <dd> <meter min=0 max=20 value=12>12cm</meter>
 <dt>Height: <dd> <meter min=0 max=10 value=2>2cm</meter>
</dl>
```

There is no explicit way to specify units in the `meter`<sup>p519</sup> element, but the units may be specified in the `title`<sup>p122</sup> attribute in free-form text.

### Example

The example above could be extended to mention the units:

```
<dl>
 <dt>Radius: <dd> <meter min=0 max=20 value=12 title="centimeters">12cm</meter>
 <dt>Height: <dd> <meter min=0 max=10 value=2 title="centimeters">2cm</meter>
</dl>
```

**User agent requirements:** User agents must parse the `min`<sup>p520</sup>, `max`<sup>p520</sup>, `value`<sup>p520</sup>, `low`<sup>p520</sup>, `high`<sup>p520</sup>, and `optimum`<sup>p520</sup> attributes using the [rules for parsing floating-point number values](#)<sup>p62</sup>.

User agents must then use all these numbers to obtain values for six points on the gauge, as follows. (The order in which these are evaluated is important, as some of the values refer to earlier ones.)

#### The `minimum` value

If the `min`<sup>p520</sup> attribute is specified and a value could be parsed out of it, then the minimum value is that value. Otherwise, the minimum value is zero.

#### The `maximum` value

If the `max`<sup>p520</sup> attribute is specified and a value could be parsed out of it, then the candidate maximum value is that value. Otherwise, the candidate maximum value is 1.0.

If the candidate maximum value is greater than or equal to the minimum value, then the maximum value is the candidate maximum value. Otherwise, the maximum value is the same as the minimum value.

### **The *actual value***

If the `valueb520` attribute is specified and a value could be parsed out of it, then that value is the candidate actual value. Otherwise, the candidate actual value is zero.

If the candidate actual value is less than the minimum value, then the actual value is the minimum value.

Otherwise, if the candidate actual value is greater than the maximum value, then the actual value is the maximum value.

Otherwise, the actual value is the candidate actual value.

### **The *low boundary***

If the `lowb520` attribute is specified and a value could be parsed out of it, then the candidate low boundary is that value. Otherwise, the candidate low boundary is the same as the minimum value.

If the candidate low boundary is less than the minimum value, then the low boundary is the minimum value.

Otherwise, if the candidate low boundary is greater than the maximum value, then the low boundary is the maximum value.

Otherwise, the low boundary is the candidate low boundary.

### **The *high boundary***

If the `highb520` attribute is specified and a value could be parsed out of it, then the candidate high boundary is that value. Otherwise, the candidate high boundary is the same as the maximum value.

If the candidate high boundary is less than the low boundary, then the high boundary is the low boundary.

Otherwise, if the candidate high boundary is greater than the maximum value, then the high boundary is the maximum value.

Otherwise, the high boundary is the candidate high boundary.

### **The *optimum point***

If the `optimumb520` attribute is specified and a value could be parsed out of it, then the candidate optimum point is that value. Otherwise, the candidate optimum point is the midpoint between the minimum value and the maximum value.

If the candidate optimum point is less than the minimum value, then the optimum point is the minimum value.

Otherwise, if the candidate optimum point is greater than the maximum value, then the optimum point is the maximum value.

Otherwise, the optimum point is the candidate optimum point.

All of which will result in the following inequalities all being true:

- minimum value ≤ actual value ≤ maximum value
- minimum value ≤ low boundary ≤ high boundary ≤ maximum value
- minimum value ≤ optimum point ≤ maximum value

**UA requirements for regions of the gauge:** If the optimum point is equal to the low boundary or the high boundary, or anywhere in between them, then the region between the low and high boundaries of the gauge must be treated as the optimum region, and the low and high parts, if any, must be treated as suboptimal. Otherwise, if the optimum point is less than the low boundary, then the region between the minimum value and the low boundary must be treated as the optimum region, the region from the low boundary up to the high boundary must be treated as a suboptimal region, and the remaining region must be treated as an even less good region. Finally, if the optimum point is higher than the high boundary, then the situation is reversed; the region between the high boundary and the maximum value must be treated as the optimum region, the region from the high boundary down to the low boundary must be treated as a suboptimal region, and the remaining region must be treated as an even less good region.

**UA requirements for showing the gauge:** When representing a `meterb519` element to the user, the UA should indicate the relative position of the actual value to the minimum and maximum values, and the relationship between the actual value and the three regions of the gauge.

#### **Example**

The following markup:

```
<h3>Suggested groups</h3>
<menu type="toolbar">
 Hide suggested groups
```

```

</menu>

 <p>comp.infosystems.www.authoring.stylesheets -

 join</p>
 <p>Group description: Layout/presentation on the WWW.</p>
 <p><meter value="0.5">Moderate activity,</meter> Usenet, 618 subscribers</p>

 <p>netscape.public.mozilla.xpininstall -

 join</p>
 <p>Group description: Mozilla XPIInstall discussion.</p>
 <p><meter value="0.25">Low activity,</meter> Usenet, 22 subscribers</p>

 <p>mozilla.dev.general -

 join</p>
 <p><meter value="0.25">Low activity,</meter> Usenet, 66 subscribers</p>

```

Might be rendered as follows:

User agents may combine the value of the `title`<sup>p122</sup> attribute and the other attributes to provide context-sensitive help or inline text detailing the actual values.

### Example

For example, the following snippet:

```
<meter min=0 max=60 value=23.2 title="seconds"></meter>
```

...might cause the user agent to display a gauge with a tooltip saying "Value: 23.2 out of 60." on one line and "seconds" on a second line.

The `value` IDL attribute, on getting, must return the [actual value](#)<sup>p522</sup>. On setting, the given value must be converted to the [best representation of the number as a floating-point number](#)<sup>p62</sup> and then the [value](#)<sup>p523</sup> content attribute must be set to that string.

The `min` IDL attribute, on getting, must return the [minimum value](#)<sup>p521</sup>. On setting, the given value must be converted to the [best representation of the number as a floating-point number](#)<sup>p62</sup> and then the [min](#)<sup>p523</sup> content attribute must be set to that string.

The `max` IDL attribute, on getting, must return the [maximum value](#)<sup>p521</sup>. On setting, the given value must be converted to the [best representation of the number as a floating-point number](#)<sup>p62</sup> and then the [max](#)<sup>p523</sup> content attribute must be set to that string.

The `low` IDL attribute, on getting, must return the [low boundary](#)<sup>p522</sup>. On setting, the given value must be converted to the [best representation of the number as a floating-point number](#)<sup>p62</sup> and then the [low](#)<sup>p523</sup> content attribute must be set to that string.

The `high` IDL attribute, on getting, must return the [high boundary<sup>p522</sup>](#). On setting, the given value must be converted to the [best representation of the number as a floating-point number<sup>p62</sup>](#) and then the `highp524` content attribute must be set to that string.

The `optimum` IDL attribute, on getting, must return the [optimum value<sup>p522</sup>](#). On setting, the given value must be converted to the [best representation of the number as a floating-point number<sup>p62</sup>](#) and then the `optimump524` content attribute must be set to that string.

The `labelsp452` IDL attribute provides a list of the element's `labelp451`s.

### Example

The following example shows how a gauge could fall back to localised or pretty-printed text.

```
<p>Disk usage: <meter min=0 value=170261928 max=233257824>170 261 928 bytes used
out of 233 257 824 bytes available</meter></p>
```

## 4.10.16 The `fieldset` element

Spec bugs: [25551](#)

Categories<sup>p113</sup>:

[Flow content<sup>p115</sup>](#).

[Sectioning root<sup>p176</sup>](#).

[Listed<sup>p446</sup>](#) and [reassociateable<sup>p447</sup>](#) [form-associated element<sup>p446</sup>](#).

[Palpable content<sup>p117</sup>](#).

Contexts in which this element can be used<sup>p113</sup>:

Where [flow content<sup>p115</sup>](#) is expected.

Content model<sup>p113</sup>:

Optionally a [legend<sup>p526</sup>](#) element, followed by [flow content<sup>p115</sup>](#).

Tag omission in text/html<sup>p113</sup>:

Neither tag is omissible.

Content attributes<sup>p113</sup>:

[Global attributes<sup>p120</sup>](#)

[disabled<sup>p525</sup>](#) — Whether the form control is disabled

[form<sup>p527</sup>](#) — Associates the control with a [form<sup>p447</sup>](#) element

[name<sup>p529</sup>](#) — Name of form control to use in the [form.elements<sup>p449</sup>](#) API

DOM interface<sup>p113</sup>:

```
IDL
interface HTMLFieldSetElement : HTMLElement {
 attribute boolean disabled;
 readonly attribute HTMLFormElement? form;
 attribute DOMString name;

 readonly attribute DOMString type;

 readonly attribute HTMLFormControlsCollection elements;

 readonly attribute boolean willValidate;
 [SameObject] readonly attribute ValidityState validity;
 readonly attribute DOMString validationMessage;
 boolean checkValidity();
 boolean reportValidity();
 void setCustomValidity(DOMString error);
};
```

The `fieldsetp524` element [represents<sup>p111</sup>](#) a set of form controls optionally grouped under a common name.

The name of the group is given by the first `legend`<sup>p526</sup> element that is a child of the `fieldset`<sup>p524</sup> element, if any. The remainder of the descendants form the group.

The `disabled` attribute, when specified, causes all the form control descendants of the `fieldset`<sup>p524</sup> element, excluding those that are descendants of the `fieldset`<sup>p524</sup> element's first `legend`<sup>p526</sup> element child, if any, to be `disabled`<sup>p530</sup>.

A `fieldset`<sup>p524</sup> element is a **disabled fieldset** if it matches any of the following conditions:

- Its `disabled`<sup>p525</sup> attribute is specified
- It is a descendant of another `fieldset`<sup>p524</sup> element whose `disabled`<sup>p525</sup> attribute is specified, and is *not* a descendant of that `fieldset`<sup>p524</sup> element's first `legend`<sup>p526</sup> element child, if any.

The `form`<sup>p527</sup> attribute is used to explicitly associate the `fieldset`<sup>p524</sup> element with its `form owner`<sup>p527</sup>. The `name`<sup>p529</sup> attribute represents the element's name.

#### Note

`fieldset . type`<sup>p525</sup>

Returns the string "fieldset".

`fieldset . elements`<sup>p525</sup>

Returns an `HTMLFormControlsCollection`<sup>p91</sup> of the form controls in the element.

The `disabled` IDL attribute must `reflect`<sup>p88</sup> the content attribute of the same name.

The `type` IDL attribute must return the string "fieldset".

The `elements` IDL attribute must return an `HTMLFormControlsCollection`<sup>p91</sup> rooted at the `fieldset`<sup>p524</sup> element, whose filter matches `listed elements`<sup>p446</sup>.

The `willValidate`<sup>p555</sup>, `validity`<sup>b556</sup>, and `validationMessage`<sup>p557</sup> attributes, and the `checkValidity()`<sup>p556</sup>, `reportValidity()`<sup>p557</sup>, and `setCustomValidity()`<sup>p555</sup> methods, are part of the `constraint validation API`<sup>p524</sup>. The `form`<sup>p529</sup> and `name`<sup>p529</sup> IDL attributes are part of the element's forms API.

#### Example

This example shows a `fieldset`<sup>p524</sup> element being used to group a set of related controls:

```
<fieldset>
 <legend>Display</legend>
 <p><label><input type=radio name=c value=0 checked> Black on White</label>
 <p><label><input type=radio name=c value=1> White on Black</label>
 <p><label><input type=checkbox name=g> Use grayscale</label>
 <p><label>Enhance contrast <input type=range name=e list=contrast min=0 max=100 value=0
 step=1></label>
 <datalist id=contrast>
 <option label=Normal value=0>
 <option label=Maximum value=100>
 </datalist>
</fieldset>
```

#### Example

The following snippet shows a fieldset with a checkbox in the legend that controls whether or not the fieldset is enabled. The contents of the fieldset consist of two required text fields and an optional year/month control.

```
<fieldset name="clubfields" disabled>
 <legend> <label>
 <input type=checkbox name=club onchange="form.clubfields.disabled = !checked">
 Use Club Card
 </label> </legend>
 <p><label>Name on card: <input name=clubname required></label></p>
```

```

<p><label>Card number: <input name=clubnum required pattern="[-0-9]+"/></label></p>
<p><label>Expiry date: <input name=clubexp type=month></label></p>
</fieldset>

```

### Example

You can also nest [fieldset<sup>p524</sup>](#) elements. Here is an example expanding on the previous one that does so:

```

<fieldset name="clubfields" disabled>
 <legend> <label>
 <input type=checkbox name=club onchange="form.clubfields.disabled = !checked">
 Use Club Card
 </label> </legend>
 <p><label>Name on card: <input name=clubname required></label></p>
 <fieldset name="numfields">
 <legend> <label>
 <input type=radio checked name=clubtype onchange="form.numfields.disabled = !checked">
 My card has numbers on it
 </label> </legend>
 <p><label>Card number: <input name=clubnum required pattern="[-0-9]+"/></label></p>
 </fieldset>
 <fieldset name="letfields" disabled>
 <legend> <label>
 <input type=radio name=clubtype onchange="form.letfields.disabled = !checked">
 My card has letters on it
 </label> </legend>
 <p><label>Card code: <input name=clublet required pattern="[A-Za-z]+"/></label></p>
 </fieldset>
</fieldset>

```

In this example, if the outer "Use Club Card" checkbox is not checked, everything inside the outer [fieldset<sup>p524</sup>](#), including the two radio buttons in the legends of the two nested [fieldset<sup>p524</sup>](#)s, will be disabled. However, if the checkbox is checked, then the radio buttons will both be enabled and will let you select which of the two inner [fieldset<sup>p524</sup>](#)s is to be enabled.

## 4.10.17 The **legend** element

**Categories<sup>p113</sup>:**

None.

**Contexts in which this element can be used<sup>p113</sup>:**

As the first child of a [fieldset<sup>p524</sup>](#) element.

**Content model<sup>p113</sup>:**

[Phrasing content<sup>p116</sup>](#).

**Tag omission in text/html<sup>p113</sup>:**

Neither tag is omissible.

**Content attributes<sup>p113</sup>:**

[Global attributes<sup>p120</sup>](#)

**DOM interface<sup>p113</sup>:**

IDL	<pre> interface HTMLLegendElement : HTMLElement {   readonly attribute HTMLFormElement? form;    // also has obsolete members }; </pre>
-----	-----------------------------------------------------------------------------------------------------------------------------------------

The [legend<sup>p526</sup>](#) element [represents<sup>p111</sup>](#) a caption for the rest of the contents of the [legend<sup>p526</sup>](#) element's parent [fieldset<sup>p524</sup>](#) element, if any.

**Note**

`legend . formp527`

Returns the element's `formp447` element, if any, or null otherwise.

The `form` IDL attribute's behaviour depends on whether the `legendp526` element is in a `fieldsetp524` element or not. If the `legendp526` has a `fieldsetp524` element as its parent, then the `formp527` IDL attribute must return the same value as the `formp529` IDL attribute on that `fieldsetp524` element. Otherwise, it must return null.

## 4.10.18 Form control infrastructure

### 4.10.18.1 A form control's value

Most form controls have a **value** and a **checkedness**. (The latter is only used by `inputp452` elements.) These are used to describe how the user interacts with the control.

A control's `valuep527` is its internal state. As such, it might not match the user's current input.

**Example** For instance, if a user enters the word "three" into `a numeric fieldp469` that expects digits, the user's input would be the string "three" but the control's `valuep527` would remain unchanged.

To define the behaviour of constraint validation in the face of the `inputp452` element's `multiplep485` attribute, `inputp452` elements can also have separately defined **values**.

The `selectp498` element does not have a `valuep527`; the **selectedness** of its `optionp505` elements is what is used instead.

### 4.10.18.2 Mutability

A form control can be designated as **mutable**.

**Note** This determines (by means of definitions and requirements in this specification that rely on whether an element is so designated) whether or not the user can modify the `valuep527` or `checkednessp527` of a form control, or whether or not a control can be automatically prefilled.

### 4.10.18.3 Association of controls and forms

Spec bugs: [27678](#)

A `form-associated elementp446` can have a relationship with a `formp447` element, which is called the element's **form owner**. If a `form-associated elementp446` is not associated with a `formp447` element, its `form ownerp527` is said to be null.

A `form-associated elementp446` is, by default, associated with its nearest ancestor `formp447` element (as described below), but, if it is `reassociateablep447`, may have a `form` attribute specified to override this.

**Note** This feature allows authors to work around the lack of support for nested `formp447` elements.

If a `reassociateablep447` `form-associated elementp446` has a `formp527` attribute specified, then that attribute's value must be the `IDp51` of a `formp447` element in the element's owner `Documentp102`.

**Note** The rules in this section are complicated by the fact that although conforming documents will never contain nested `formp447` elements, it is quite possible (e.g. using a script that performs DOM manipulation) to generate documents that have such nested elements. They are also complicated by rules in the HTML parser that, for historical reasons, can result in a `form-associated elementp446` being associated with a `formp447` element that is not its ancestor.

When a `form-associated elementp446` is created, its `form ownerp527` must be initialised to null (no owner).

When a `form-associated elementp446` is to be **associated** with a form, its `form ownerp527` must be set to that form.

**Note**

When a [form-associated element<sup>p446</sup>](#) or one of its ancestors is [inserted into a Document<sup>p42</sup>](#), then the user agent must [reset the form owner<sup>p528</sup>](#) of that [form-associated element<sup>p446</sup>](#). The HTML parser<sup>p952</sup> overrides this requirement when inserting form controls.

When an element changes its parent node resulting in a [form-associated element<sup>p446</sup>](#) and its [form owner<sup>p527</sup>](#) (if any) no longer being in the same [home subtree<sup>p42</sup>](#), then the user agent must [reset the form owner<sup>p528</sup>](#) of that [form-associated element<sup>p446</sup>](#).

When a [reassociateable<sup>p447</sup>](#) [form-associated element<sup>p446</sup>](#)'s [form<sup>p527</sup>](#) attribute is set, changed, or removed, then the user agent must [reset the form owner<sup>p528</sup>](#) of that element.

When a [reassociateable<sup>p447</sup>](#) [form-associated element<sup>p446</sup>](#) has a [form<sup>p527</sup>](#) attribute and the [ID<sup>p51</sup>](#) of any of the elements in the [Document<sup>p102</sup>](#) changes, then the user agent must [reset the form owner<sup>p528</sup>](#) of that [form-associated element<sup>p446</sup>](#).

When a [reassociateable<sup>p447</sup>](#) [form-associated element<sup>p446</sup>](#) has a [form<sup>p527</sup>](#) attribute and an element with an [ID<sup>p51</sup>](#) is [inserted into<sup>p42</sup>](#) or [removed from<sup>p42</sup>](#) the [Document<sup>p102</sup>](#), then the user agent must [reset the form owner<sup>p528</sup>](#) of that [form-associated element<sup>p446</sup>](#).

When the user agent is to [reset the form owner](#) of a [form-associated element<sup>p446</sup>](#), it must run the following steps:

1. If the element's [form owner<sup>p527</sup>](#) is not null, and either the element is not [reassociateable<sup>p447</sup>](#) or its [form<sup>p527</sup>](#) content attribute is not present, and the element's [form owner<sup>p527</sup>](#) is its nearest [form<sup>p447</sup>](#) element ancestor after the change to the ancestor chain, then do nothing, and abort these steps.
2. Let the element's [form owner<sup>p527</sup>](#) be null.
3. If the element is [reassociateable<sup>p447</sup>](#), has a [form<sup>p527</sup>](#) content attribute, and is itself in a [Document<sup>p42</sup>](#), then run these substeps:
  1. If the first element [in the Document<sup>p42</sup>](#) to have an [ID<sup>p51</sup>](#) that is [case-sensitively<sup>p58</sup>](#) equal to the element's [form<sup>p527</sup>](#) content attribute's value is a [form<sup>p447</sup>](#) element, then [associate<sup>p527</sup>](#) the [form-associated element<sup>p446</sup>](#) with that [form<sup>p447</sup>](#) element.
  2. Abort the "reset the form owner" steps.
4. Otherwise, if the [form-associated element<sup>p446</sup>](#) in question has an ancestor [form<sup>p447</sup>](#) element, then [associate<sup>p527</sup>](#) the [form-associated element<sup>p446</sup>](#) with the nearest such ancestor [form<sup>p447</sup>](#) element.
5. Otherwise, the element is left unassociated.

**Example**

In the following non-conforming snippet:

```
...
<form id="a">
 <div id="b"></div>
</form>
<script>
 document.getElementById('b').innerHTML =
 '<table><tr><td><form id="c"><input id="d"></table>' +
 '<input id="e">';
</script>
...
```

The [form owner<sup>p527</sup>](#) of "d" would be the inner nested form "c", while the [form owner<sup>p527</sup>](#) of "e" would be the outer form "a".

This happens as follows: First, the "e" node gets associated with "c" in the [HTML parser<sup>p952</sup>](#). Then, the [innerHTML<sup>p52</sup>](#) algorithm moves the nodes from the temporary document to the "b" element. At this point, the nodes see their ancestor chain change, and thus all the "magic" associations done by the parser are reset to normal ancestor associations.

This example is a non-conforming document, though, as it is a violation of the content models to nest [form<sup>p447</sup>](#) elements.

**Note**

`element.formp529`

Returns the element's [form owner<sup>p527</sup>](#).

Returns null if there isn't one.

[Reassociateable](#)<sup>p447</sup> [form-associated elements](#)<sup>p446</sup> have a `form` IDL attribute, which, on getting, must return the element's [form owner](#)<sup>p527</sup>, or null if there isn't one.

#### 4.10.19 Attributes common to form controls

##### 4.10.19.1 Naming form controls: the `name`<sup>p529</sup> attribute

The `name` content attribute gives the name of the form control, as used in [form submission](#)<sup>p557</sup> and in the `form`<sup>p447</sup> element's `elements`<sup>p449</sup> object. If the attribute is specified, its value must not be the empty string.

Any non-empty value for `name`<sup>b448</sup> is allowed, but the names "`charset`<sup>p529</sup>" and "`isindex`<sup>p529</sup>" are special:

###### `isindex`

This value, if used as the name of a [Text](#)<sup>p458</sup> control that is the first control in a form that is submitted using the [application/x-www-form-urlencoded](#)<sup>p532</sup> mechanism, causes the submission to only include the value of this control, with no name.

###### `charset`

This value, if used as the name of a [Hidden](#)<sup>p458</sup> control with no `value`<sup>p457</sup> attribute, is automatically given a value during submission consisting of the submission character encoding.

The `name` IDL attribute must [reflect](#)<sup>p88</sup> the `name`<sup>p529</sup> content attribute.

##### 4.10.19.2 Submitting element directionality: the `dirname`<sup>p529</sup> attribute

The `dirname` attribute on a form control element enables the submission of [the directionality](#)<sup>p125</sup> of the element, and gives the name of the field that contains this value during [form submission](#)<sup>p557</sup>. If such an attribute is specified, its value must not be the empty string.

###### Example

In this example, a form contains a text field and a submission button:

```
<form action="addcomment.cgi" method=post>
 <p><label>Comment: <input type=text name="comment" dirname="comment.dir" required></label></p>
 <p><button name="mode" type=submit value="add">Post Comment</button></p>
</form>
```

When the user submits the form, the user agent includes three fields, one called "comment", one called "comment.dir", and one called "mode"; so if the user types "Hello", the submission body might be something like:

```
comment=Hello&comment.dir=ltr&mode=add
```

If the user manually switches to a right-to-left writing direction and enters "مرحبا", the submission body might be something like:

```
comment=%D9%85%D8%B1%D8%AD%D8%A8%D8%A7&comment.dir=rtl&mode=add
```

##### 4.10.19.3 Limiting user input length: the `maxlength`<sup>p529</sup> attribute

A `form control` `maxlength` attribute, controlled by a *dirty value flag*, declares a limit on the number of characters a user can input.

If an element has its [form control](#) `maxlength` attribute<sup>b529</sup> specified, the attribute's value must be a [valid non-negative integer](#)<sup>p61</sup>. If the attribute is specified and applying the [rules for parsing non-negative integers](#)<sup>p61</sup> to its value results in a number, then that number is the element's **maximum allowed value length**. If the attribute is omitted or parsing its value results in an error, then there is no [maximum allowed value length](#)<sup>p529</sup>.

**Constraint validation:** If an element has a [maximum allowed value length](#)<sup>p529</sup>, its *dirty value flag* is true, its `value`<sup>p527</sup> was last changed by a user edit (as opposed to a change made by a script), and the `code-unit length`<sup>p44</sup> of the element's `value`<sup>p527</sup> is greater than the element's [maximum allowed value length](#)<sup>p529</sup>, then the element is [suffering from being too long](#)<sup>p553</sup>.

User agents may prevent the user from causing the element's [value](#)<sup>p527</sup> to be set to a value whose [code-unit length](#)<sup>p44</sup> is greater than the element's [maximum allowed value length](#)<sup>p529</sup>.

**Note** In the case of [textarea](#)<sup>p508</sup> elements, this is the [value](#)<sup>p527</sup>, not the [raw value](#)<sup>p509</sup>, so the [textarea wrapping transformation](#)<sup>p511</sup> is applied before the [maximum allowed value length](#)<sup>p529</sup> is checked.

#### 4.10.19.4 Setting minimum input length requirements: the [minlength](#)<sup>p530</sup> attribute

A form control [minlength](#) attribute, controlled by a *dirty value flag*, declares a lower bound on the number of characters a user can input.

**Note** The [minlength](#)<sup>p530</sup> attribute does not imply the [required](#) attribute. If the form control has no [required](#) attribute, then the value can still be omitted; the [minlength](#)<sup>p530</sup> attribute only kicks in once the user has entered a value at all. If the empty string is not allowed, then the [required](#) attribute also needs to be set.

If an element has its [form control minlength attribute](#)<sup>p530</sup> specified, the attribute's value must be a [valid non-negative integer](#)<sup>p61</sup>. If the attribute is specified and applying the [rules for parsing non-negative integers](#)<sup>p61</sup> to its value results in a number, then that number is the element's [minimum allowed value length](#). If the attribute is omitted or parsing its value results in an error, then there is no [minimum allowed value length](#)<sup>p530</sup>.

If an element has both a [maximum allowed value length](#)<sup>p529</sup> and a [minimum allowed value length](#)<sup>p530</sup>, the [minimum allowed value length](#)<sup>p530</sup> must be smaller than or equal to the [maximum allowed value length](#)<sup>p529</sup>.

**Constraint validation:** If an element has a [minimum allowed value length](#)<sup>p530</sup>, its [value](#)<sup>p527</sup> is not the empty string, and the [code-unit length](#)<sup>p44</sup> of the element's [value](#)<sup>p527</sup> is less than the element's [minimum allowed value length](#)<sup>p530</sup>, then the element is [suffering from being too short](#)<sup>p553</sup>.

##### Example

In this example, there are four text fields. The first is required, and has to be at least 5 characters long. The other three are optional, but if the user fills one in, the user has to enter at least 10 characters.

```
<form action="/events/menu.cgi" method="post">
<p><label>Name of Event: <input required minlength=5 maxlength=50 name=event></label></p>
<p><label>Describe what you would like for breakfast, if anything:
 <textarea name="breakfast" minlength="10"></textarea></label></p>
<p><label>Describe what you would like for lunch, if anything:
 <textarea name="lunch" minlength="10"></textarea></label></p>
<p><label>Describe what you would like for dinner, if anything:
 <textarea name="dinner" minlength="10"></textarea></label></p>
<p><input type=submit value="Submit Request"></p>
</form>
```

#### 4.10.19.5 Enabling and disabling form controls: the [disabled](#)<sup>p530</sup> attribute

The [disabled](#) content attribute is a [boolean attribute](#)<sup>p59</sup>.

A form control is [disabled](#) if any of the following conditions are met:

1. The element is a [button](#)<sup>p495</sup>, [input](#)<sup>p452</sup>, [select](#)<sup>p498</sup>, or [textarea](#)<sup>p508</sup> element, and the [disabled](#)<sup>p530</sup> attribute is specified on this element (regardless of its value).
2. The element is a descendant of a [fieldset](#)<sup>p524</sup> element whose [disabled](#)<sup>p525</sup> attribute is specified, and is *not* a descendant of that [fieldset](#)<sup>p524</sup> element's first [legend](#)<sup>p526</sup> element child, if any.

A form control that is [disabled](#)<sup>p530</sup> must prevent any [click](#)<sup>p52</sup> events that are [queued](#)<sup>p835</sup> on the [user interaction task source](#)<sup>p838</sup> from being dispatched on the element.

**Constraint validation:** If an element is [disabled](#)<sup>p530</sup>, it is [barred from constraint validation](#)<sup>p553</sup>.

The [disabled](#) IDL attribute must [reflect](#)<sup>p88</sup> the [disabled](#)<sup>p530</sup> content attribute.

#### 4.10.19.6 Form submission

Attributes for form submission can be specified both on [form<sup>p447</sup>](#) elements and on [submit buttons<sup>p447</sup>](#) (elements that represent buttons that submit forms, e.g. an [input<sup>p452</sup>](#) element whose [type<sup>p454</sup>](#) attribute is in the [Submit Button<sup>p478</sup>](#) state).

The [attributes for form submission<sup>p531</sup>](#) that may be specified on [form<sup>p447</sup>](#) elements are [action<sup>p531</sup>](#), [enctype<sup>p532</sup>](#), [method<sup>p531</sup>](#), [novalidate<sup>b532</sup>](#), and [target<sup>p532</sup>](#).

The corresponding [attributes for form submission<sup>p531</sup>](#) that may be specified on [submit buttons<sup>p447</sup>](#) are [formaction<sup>p531</sup>](#), [formenctype<sup>p532</sup>](#), [formmethod<sup>p531</sup>](#), [formnovalidate<sup>p532</sup>](#), and [formtarget<sup>b532</sup>](#). When omitted, they default to the values given on the corresponding attributes on the [form<sup>p447</sup>](#) element.

The [action](#) and [formaction](#) content attributes, if specified, must have a value that is a [valid non-empty URL potentially surrounded by spaces<sup>p82</sup>](#).

The [action](#) of an element is the value of the element's [formaction<sup>p531</sup>](#) attribute, if the element is a [submit button<sup>p447</sup>](#) and has such an attribute, or the value of its [form owner<sup>p527</sup>](#)'s [action<sup>p531</sup>](#) attribute, if it has one, or else the empty string.

The [method](#) and [formmethod](#) content attributes are [enumerated attributes<sup>p60</sup>](#) with the following keywords and states:

- The keyword [get](#), mapping to the state **GET**, indicating the HTTP GET method.
- The keyword [post](#), mapping to the state **POST**, indicating the HTTP POST method.
- The keyword [dialog](#), mapping to the state **dialog**, indicating that submitting the [form<sup>p447</sup>](#) is intended to close the [dialog<sup>p586</sup>](#) box in which the form finds itself, if any, and otherwise not submit.

The [invalid value default<sup>p60</sup>](#) for these attributes is the [GET<sup>p531</sup>](#) state. The [missing value default<sup>p60</sup>](#) for the [method<sup>p531</sup>](#) attribute is also the [GET<sup>p531</sup>](#) state. (There is no [missing value default<sup>p60</sup>](#) for the [formmethod<sup>p531</sup>](#) attribute.)

The [method](#) of an element is one of those states. If the element is a [submit button<sup>p447</sup>](#) and has a [formmethod<sup>p531</sup>](#) attribute, then the element's [method<sup>p531</sup>](#) is that attribute's state; otherwise, it is the [form owner<sup>p527</sup>](#)'s [method<sup>p531</sup>](#) attribute's state.

##### Example

Here the [method<sup>p531</sup>](#) attribute is used to explicitly specify the default value, "[get<sup>p531</sup>](#)", so that the search query is submitted in the URL:

```
<form method="get" action="/search.cgi">
 <p><label>Search terms: <input type=search name=q></label></p>
 <p><input type=submit></p>
</form>
```

##### Example

On the other hand, here the [method<sup>p531</sup>](#) attribute is used to specify the value "[post<sup>p531</sup>](#)", so that the user's message is submitted in the HTTP request's body:

```
<form method="post" action="/post-message.cgi">
 <p><label>Message: <input type=text name=m></label></p>
 <p><input type=submit value="Submit message"></p>
</form>
```

##### Example

In this example, a [form<sup>p447</sup>](#) is used with a [dialog<sup>p586</sup>](#). The [method<sup>p531</sup>](#) attribute's "[dialog<sup>p531</sup>](#)" keyword is used to have the dialog automatically close when the form is submitted.

```
<dialog id="ship">
 <form method=dialog>
 <p>A ship has arrived in the harbour.</p>
 <button type=submit value="board">Board the ship</button>
 <button type=submit value="call">Call to the captain</button>
 </form>
```

```

</dialog>
<script>
 var ship = document.getElementById('ship');
 ship.showModal();
 ship.onclose = function (event) {
 if (ship.returnValue == 'board') {
 // ...
 } else {
 // ...
 }
 };
</script>

```

The **enctype** and **formenctype** content attributes are [enumerated attributes<sup>p60</sup>](#) with the following keywords and states:

- The "**application/x-www-form-urlencoded**" keyword and corresponding state.
- The "**multipart/form-data**" keyword and corresponding state.
- The "**text/plain**" keyword and corresponding state.

The [invalid value default<sup>p60</sup>](#) for these attributes is the [application/x-www-form-urlencoded<sup>p532</sup>](#) state. The [missing value default<sup>p60</sup>](#) for the **enctype**<sup>p532</sup> attribute is also the [application/x-www-form-urlencoded<sup>p532</sup>](#) state. (There is no [missing value default<sup>p60</sup>](#) for the **formenctype**<sup>p532</sup> attribute.)

The **enctype** of an element is one of those three states. If the element is a [submit button<sup>p447</sup>](#) and has a [formenctype<sup>p532</sup>](#) attribute, then the element's **enctype**<sup>p532</sup> is that attribute's state; otherwise, it is the [form owner<sup>p527</sup>](#)'s [enctype<sup>p532</sup>](#) attribute's state.

The **target** and **formtarget** content attributes, if specified, must have values that are [valid browsing context names or keywords<sup>p766</sup>](#).

The **target** of an element is the value of the element's [formtarget<sup>p532</sup>](#) attribute, if the element is a [submit button<sup>p447</sup>](#) and has such an attribute; or the value of its [form owner<sup>p527</sup>](#)'s [target<sup>p532</sup>](#) attribute, if it has such an attribute; or, if the [Document<sup>p102</sup>](#) contains a [base<sup>p140</sup>](#) element with a [target<sup>p140</sup>](#) attribute, then the value of the [target<sup>p140</sup>](#) attribute of the first such [base<sup>p140</sup>](#) element; or, if there is no such element, the empty string.

The **novalidate** and **formnovalidate** content attributes are [boolean attributes<sup>p59</sup>](#). If present, they indicate that the form is not to be validated during submission.

The **no-validate state** of an element is true if the element is a [submit button<sup>p447</sup>](#) and the element's [formnovalidate<sup>p532</sup>](#) attribute is present, or if the element's [form owner<sup>p527</sup>](#)'s [novalidate<sup>p532</sup>](#) attribute is present, and false otherwise.

### Example

This attribute is useful to include "save" buttons on forms that have validation constraints, to allow users to save their progress even though they haven't fully entered the data in the form. The following example shows a simple form that has two required fields. There are three buttons: one to submit the form, which requires both fields to be filled in; one to save the form so that the user can come back and fill it in later; and one to cancel the form altogether.

```

<form action="editor.cgi" method="post">
 <p><label>Name: <input required name=fn></label></p>
 <p><label>Essay: <textarea required name=essay></textarea></label></p>
 <p><input type=submit name=submit value="Submit essay"></p>
 <p><input type=submit formnovalidate name=save value="Save essay"></p>
 <p><input type=submit formnovalidate name=cancel value="Cancel"></p>
</form>

```

The **action** IDL attribute must [reflect<sup>p88</sup>](#) the content attribute of the same name, except that on getting, when the content attribute is missing or its value is the empty string, [the document's address](#) must be returned instead. The **target** IDL attribute must [reflect<sup>p88</sup>](#) the content attribute of the same name. The **method** and **enctype** IDL attributes must [reflect<sup>p88</sup>](#) the respective content attributes of the same name, [limited to only known](#)

values<sup>p89</sup>. The encoding IDL attribute must reflect<sup>p88</sup> the enctype<sup>p532</sup> content attribute, limited to only known values<sup>p89</sup>. The noValidate IDL attribute must reflect<sup>p88</sup> the novalidate<sup>p532</sup> content attribute. The formAction IDL attribute must reflect<sup>p88</sup> the formaction<sup>p531</sup> content attribute, except that on getting, when the content attribute is missing or its value is the empty string, the document's address must be returned instead. The formEnctype IDL attribute must reflect<sup>p88</sup> the formenctype<sup>p532</sup> content attribute, limited to only known values<sup>p89</sup>. The formMethod IDL attribute must reflect<sup>p88</sup> the formmethod<sup>p531</sup> content attribute, limited to only known values<sup>p89</sup>. The formNoValidate IDL attribute must reflect<sup>p88</sup> the formnovalidate<sup>p532</sup> content attribute. The formTarget IDL attribute must reflect<sup>p88</sup> the formtarget<sup>p532</sup> content attribute.

#### 4.10.19.6.1 Autofocusing a form control: the autofocus<sup>p533</sup> attribute

The autofocus content attribute allows the author to indicate that a control is to be focused as soon as the page is loaded or as dialog<sup>p586</sup> within which it finds itself is shown, allowing the user to just start typing without having to manually focus the main control.

The autofocus<sup>p533</sup> attribute is a boolean attribute<sup>p59</sup>.

An element's **nearest ancestor autofocus scoping root element** is the element itself if the element is a dialog<sup>p586</sup> element, or the element's nearest ancestor dialog<sup>p586</sup> element, if any, or else is the element's root element<sup>p42</sup>.

There must not be two elements with the same nearest ancestor autofocus scoping root element<sup>p533</sup> that both have the autofocus<sup>p533</sup> attribute specified.

When an element with the autofocus<sup>p533</sup> attribute specified is inserted into a document<sup>p42</sup>, user agents should run the following steps:

1. Let *target* be the element's node document.
2. If *target* has no browsing context<sup>p762</sup>, abort these steps.
3. If *target*'s browsing context<sup>p762</sup> has no top-level browsing context<sup>p763</sup> (e.g. it is a nested browsing context<sup>p763</sup> with no parent browsing context<sup>p763</sup>), abort these steps.
4. If *target*'s active sandboxing flag set<sup>p782</sup> has the sandboxed automatic features browsing context flag<sup>p780</sup>, abort these steps.
5. If *target*'s origin<sup>p776</sup> is not the same<sup>p778</sup> as the origin<sup>p776</sup> of the node document of the currently focused element in *target*'s top-level browsing context<sup>p763</sup>, abort these steps.
6. If *target*'s origin<sup>p776</sup> is not the same<sup>p778</sup> as the origin<sup>p776</sup> of the active document<sup>p762</sup> of *target*'s top-level browsing context<sup>p763</sup>, abort these steps.
7. If the user agent has already reached the last step of this list of steps in response to an element being inserted<sup>p42</sup> into a Document<sup>p102</sup> whose top-level browsing context<sup>p763</sup>'s active document<sup>p762</sup> is the same as *target*'s top-level browsing context<sup>p763</sup>'s active document<sup>p762</sup>, abort these steps.
8. If the user has indicated (for example, by starting to type in a form control) that he does not wish focus to be changed, then optionally abort these steps.
9. Queue a task<sup>p835</sup> that runs the focusing steps<sup>p730</sup> for the element. User agents may also change the scrolling position of the document, or perform some other action that brings the element to the user's attention. The task source<sup>p835</sup> for this task is the user interaction task source<sup>p838</sup>.

**Note** This handles the automatic focusing during document load. The show()<sup>p587</sup> and showModal()<sup>p587</sup> methods of dialog<sup>p586</sup> elements also processes the autofocus<sup>p533</sup> attribute.

**Note** Focusing the control does not imply that the user agent must focus the browser window if it has lost focus.

The autofocus IDL attribute must reflect<sup>p88</sup> the content attribute of the same name.

#### Example

In the following snippet, the text control would be focused when the document was loaded.

```
<input maxlength="256" name="q" value="" autofocus>
<input type="submit" value="Search">
```

Spec bugs:	26669

#### 4.10.19.7 Input modalities: the `inputmode`<sup>p534</sup> attribute

The `inputmode` content attribute is an [enumerated attribute](#)<sup>p60</sup> that specifies what kind of input mechanism would be most helpful for users entering content into the form control.

User agents must recognise all the keywords and corresponding states given below, but need not support all of the corresponding states. If a keyword's state is not supported, the user agent must act as if the keyword instead mapped to the given state's fallback state, as defined below. This fallback behaviour is transitive.

**Note** For example, if a user agent with a QWERTY keyboard layout does not support text prediction and automatic capitalization, then it could treat the `latin-prose`<sup>p534</sup> keyword in the same way as the `verbatim`<sup>p534</sup> keyword, following the chain `Latin Prose`<sup>p534</sup> → `Latin Text`<sup>p534</sup> → `Latin Verbatim`<sup>p534</sup>.

The possible keywords and states for the attributes are listed in the following table. The keywords are listed in the first column. Each maps to the state given in the cell in the second column of that keyword's row, and that state has the fallback state given in the cell in the third column of that row.

Keyword	State	Fallback state	Description
<code>verbatim</code>	<code>Latin Verbatim</code>	<code>Default</code> <sup>p534</sup>	Alphanumeric Latin-script input of non-prose content, e.g. usernames, passwords, product codes.
<code>latin</code>	<code>Latin Text</code>	<code>Latin Verbatim</code> <sup>p534</sup>	Latin-script input in the user's preferred language(s), with some typing aids enabled (e.g. text prediction). Intended for human-to-computer communications, e.g. free-form text search fields.
<code>latin-name</code>	<code>Latin Name</code>	<code>Latin Text</code> <sup>p534</sup>	Latin-script input in the user's preferred language(s), with typing aids intended for entering human names enabled (e.g. text prediction from the user's contact list and automatic capitalisation at every word). Intended for situations such as customer name fields.
<code>latin-prose</code>	<code>Latin Prose</code>	<code>Latin Text</code> <sup>p534</sup>	Latin-script input in the user's preferred language(s), with aggressive typing aids intended for human-to-human communications enabled (e.g. text prediction and automatic capitalisation at the start of sentences). Intended for situations such as e-mails and instant messaging.
<code>full-width-latin</code>	<code>Full-width Latin</code>	<code>Latin Prose</code> <sup>p534</sup>	Latin-script input in the user's secondary language(s), using full-width characters, with aggressive typing aids intended for human-to-human communications enabled (e.g. text prediction and automatic capitalisation at the start of sentences). Intended for latin text embedded inside CJK text.
<code>kana</code>	<code>Kana</code>	<code>Default</code> <sup>p534</sup>	Kana or romaji input, typically hiragana input, using full-width characters, with support for converting to kanji. Intended for Japanese text input.
<code>kana-name</code>	<code>Kana Name</code>	<code>Kana</code> <sup>p534</sup>	Kana or romaji input, typically hiragana input, using full-width characters, with support for converting to kanji, and with typing aids intended for entering human names enabled (e.g. text prediction from the user's contact list). Intended for situations such as customer name fields.
<code>katakana</code>	<code>Katakana</code>	<code>Kana</code> <sup>p534</sup>	Katakana input, using full-width characters, with support for converting to kanji. Intended for Japanese text input.
<code>numeric</code>	<code>Numeric</code>	<code>Default</code> <sup>p534</sup>	Numeric input, including keys for the digits 0 to 9, the user's preferred thousands separator character, and the character for indicating negative numbers. Intended for numeric codes, e.g. credit card numbers. (For numbers, prefer " <code>&lt;input type=number&gt;</code> " <sup>p469</sup> .)
<code>tel</code>	<code>Telephone</code>	<code>Numeric</code> <sup>p534</sup>	Telephone number input, including keys for the digits 0 to 9, the "#" character, and the "*" character. In some locales, this can also include alphabetic mnemonic labels (e.g. in the US, the key labeled "2" is historically also labeled with the letters A, B, and C). <a href="#">Rarely necessary</a> <sup>p534</sup> ; use " <code>&lt;input type=tel&gt;</code> " <sup>p459</sup> instead.
<code>email</code>	<code>E-mail</code>	<code>Default</code> <sup>p534</sup>	Text input in the user's locale, with keys for aiding in the input of e-mail addresses, such as that for the "@" character and the "." character. <a href="#">Rarely necessary</a> <sup>p534</sup> ; use " <code>&lt;input type=email&gt;</code> " <sup>p461</sup> instead.
<code>url</code>	<code>URL</code>	<code>Default</code> <sup>p534</sup>	Text input in the user's locale, with keys for aiding in the input of Web addresses, such as that for the "/" and ":" characters and for quick input of strings commonly found in domain names such as "www." or ".co.uk". <a href="#">Rarely necessary</a> <sup>p534</sup> ; use " <code>&lt;input type=url&gt;</code> " <sup>p460</sup> instead.

The last three keywords listed above are only provided for completeness, and are rarely necessary, as dedicated input controls exist for their usual use cases (as described in the table above).

User agents must all support the `Default` input mode state, which corresponds to the user agent's default input modality. This specification does not define how the user agent's default modality is to operate. The [missing value default](#)<sup>p60</sup> is the [default input mode](#)<sup>p534</sup> state.

User agents should use the input modality corresponding to the state of the `inputmode`<sup>p534</sup> attribute when exposing a user interface for editing the value of a form control to which the attribute [applies](#)<sup>p455</sup>. An input modality corresponding to a state is one designed to fit the description of the state in the table above. This value can change dynamically; user agents should update their interface as the attribute changes state, unless that would go against the user's wishes.

#### 4.10.19.8 Autofill

##### 4.10.19.8.1 Autofilling form controls: the `autocomplete`<sup>p535</sup> attribute

User agents sometimes have features for helping users fill forms in, for example prefilling the user's address based on earlier user input. The `autocomplete` content attribute can be used to hint to the user agent how to, or indeed whether to, provide such a feature.

There are two ways this attribute is used. When wearing the **autofill expectation mantle**, the `autocomplete`<sup>p535</sup> attribute describes what input is expected from users. When wearing the **autofill anchor mantle**, the `autocomplete`<sup>p535</sup> attribute describes the meaning of the given value.

On an `input`<sup>p452</sup> element whose `type`<sup>p454</sup> attribute is in the `Hidden`<sup>p458</sup> state, the `autocomplete`<sup>p535</sup> attribute wears the **autofill anchor mantle**<sup>p535</sup>. In all other cases, it wears the **autofill expectation mantle**<sup>p535</sup>.

When wearing the **autofill expectation mantle**<sup>p535</sup>, the `autocomplete`<sup>p535</sup> attribute, if specified, must have a value that is an ordered `set of space-separated tokens`<sup>p80</sup> consisting of either a single token that is an `ASCII case-insensitive`<sup>p58</sup> match for the string "`off`<sup>p536</sup>", or a single token that is an `ASCII case-insensitive`<sup>p58</sup> match for the string "`on`<sup>p537</sup>", or `autofill detail tokens`<sup>p535</sup>.

When wearing the **autofill anchor mantle**<sup>p535</sup>, the `autocomplete`<sup>p535</sup> attribute, if specified, must have a value that is an ordered `set of space-separated tokens`<sup>p80</sup> consisting of just `autofill detail tokens`<sup>p535</sup> (i.e. the "`on`<sup>p537</sup>" and "`off`<sup>p536</sup>" keywords are not allowed).

**Autofill detail tokens** are the following, in the order given below:

1. Optionally, a token whose first eight characters are an `ASCII case-insensitive`<sup>p58</sup> match for the string "`section-`", meaning that the field belongs to the named group.

###### Example

For example, if there are two shipping addresses in the form, then they could be marked up as:

```
<fieldset>
 <legend>Ship the blue gift to...</legend>
 <p> <label> Address: <input name=ba autocomplete="section-blue shipping
 street-address"> </label>
 <p> <label> City: <input name=bc autocomplete="section-blue shipping
 address-level1"> </label>
 <p> <label> Postal Code: <input name=bp autocomplete="section-blue shipping
 postal-code"> </label>
</fieldset>
<fieldset>
 <legend>Ship the red gift to...</legend>
 <p> <label> Address: <input name=ra autocomplete="section-red shipping
 street-address"> </label>
 <p> <label> City: <input name=rc autocomplete="section-red shipping
 address-level1"> </label>
 <p> <label> Postal Code: <input name=rp autocomplete="section-red shipping
 postal-code"> </label>
</fieldset>
```

2. Optionally, a token that is an `ASCII case-insensitive`<sup>p58</sup> match for one of the following strings:
  - "`shipping`", meaning the field is part of the shipping address or contact information
  - "`billing`", meaning the field is part of the billing address or contact information
3. Either of the following two options:
  - A token that is an `ASCII case-insensitive`<sup>p58</sup> match for one of the following `autofill field`<sup>p537</sup> names, excluding those that are `inappropriate for the control`<sup>p537</sup>:
    - "`name`<sup>p537</sup>"
    - "`honorific-prefix`<sup>p537</sup>"
    - "`given-name`<sup>p537</sup>"
    - "`additional-name`<sup>p537</sup>"
    - "`family-name`<sup>p537</sup>"
    - "`honorific-suffix`<sup>p537</sup>"
    - "`nickname`<sup>p537</sup>"
    - "`username`<sup>p537</sup>"
    - "`new-password`<sup>p538</sup>"

- "current-password<sup>p538</sup>"
- "organization-title<sup>p537</sup>"
- "organization<sup>p538</sup>"
- "street-address<sup>p538</sup>"
- "address-line1<sup>p538</sup>"
- "address-line2<sup>p538</sup>"
- "address-line3<sup>p538</sup>"
- "address-level4<sup>p538</sup>"
- "address-level3<sup>p538</sup>"
- "address-level2<sup>p538</sup>"
- "address-level1<sup>p538</sup>"
- "country<sup>p538</sup>"
- "country-name<sup>p538</sup>"
- "postal-code<sup>p538</sup>"
- "cc-name<sup>p538</sup>"
- "cc-given-name<sup>p538</sup>"
- "cc-additional-name<sup>p538</sup>"
- "cc-family-name<sup>p538</sup>"
- "cc-number<sup>p538</sup>"
- "cc-exp<sup>p538</sup>"
- "cc-exp-month<sup>p538</sup>"
- "cc-exp-year<sup>p538</sup>"
- "cc-csc<sup>p538</sup>"
- "cc-type<sup>p538</sup>"
- "transaction-currency<sup>p538</sup>"
- "transaction-amount<sup>p538</sup>"
- "language<sup>p538</sup>"
- "bday<sup>p538</sup>"
- "bday-day<sup>p538</sup>"
- "bday-month<sup>p539</sup>"
- "bday-year<sup>p539</sup>"
- "sex<sup>p539</sup>"
- "url<sup>p539</sup>"
- "photo<sup>p539</sup>"

(See the table below for descriptions of these values.)

- The following, in the given order:
  1. Optionally, a token that is an [ASCII case-insensitive<sup>p58</sup>](#) match for one of the following strings:
    - "home", meaning the field is for contacting someone at their residence
    - "work", meaning the field is for contacting someone at their workplace
    - "mobile", meaning the field is for contacting someone regardless of location
    - "fax", meaning the field describes a fax machine's contact details
    - "pager", meaning the field describes a pager's or beeper's contact details
  2. A token that is an [ASCII case-insensitive<sup>p58</sup>](#) match for one of the following [autofill field<sup>p537</sup>](#) names, excluding those that are [inappropriate for the control<sup>p537</sup>](#).
    - "tel<sup>p539</sup>"
    - "tel-country-code<sup>p539</sup>"
    - "tel-national<sup>p539</sup>"
    - "tel-area-code<sup>p539</sup>"
    - "tel-local<sup>p539</sup>"
    - "tel-local-prefix<sup>p539</sup>"
    - "tel-local-suffix<sup>p539</sup>"
    - "tel-extension<sup>p539</sup>"
    - "email<sup>p539</sup>"
    - "impp<sup>p539</sup>"

(See the table below for descriptions of these values.)

As noted earlier, the meaning of the attribute and its keywords depends on the mantle that the attribute is wearing.

#### ↪ When wearing the [autofill expectation mantle<sup>p535</sup>](#)...

The "**off**" keyword indicates either that the control's input data is particularly sensitive (for example the activation code for a nuclear weapon); or that it is a value that will never be reused (for example a one-time-key for a bank login) and the user will therefore have to explicitly enter the data each time, instead of being able to rely on the UA to prefill the value for him; or that the document provides its own autocomplete mechanism and does not want the user agent to provide autocompletion values.

The "on" keyword indicates that the user agent is allowed to provide the user with autocompletion values, but does not provide any further information about what kind of data the user might be expected to enter. User agents would have to use heuristics to decide what autocompletion values to suggest.

The [autofill field<sup>p537</sup>](#) listed above indicate that the user agent is allowed to provide the user with autocompletion values, and specifies what kind of value is expected. The meaning of each such keyword is described in the table below.

If the [autocomplete<sup>p535</sup>](#) attribute is omitted, the default value corresponding to the state of the element's [form owner<sup>p527</sup>](#)'s [autocomplete<sup>p448</sup>](#) attribute is used instead (either "on<sup>p537</sup>" or "off<sup>p536</sup>"). If there is no [form owner<sup>p527</sup>](#), then the value "on<sup>p537</sup>" is used.

#### ↳ When wearing the [autofill anchor mantle<sup>p535</sup>](#)...

The [autofill field<sup>p537</sup>](#) listed above indicate that the value of the particular kind of value specified is that value provided for this element. The meaning of each such keyword is described in the table below.

**Example** In this example the page has explicitly specified the currency and amount of the transaction. The form requests a credit card and other billing details. The user agent could use this information to suggest a credit card that it knows has sufficient balance and that supports the relevant currency.

```
<form method=post action="step2.cgi">
 <input type=hidden autocomplete=transaction-currency value="CHF">
 <input type=hidden autocomplete=transaction-amount value="15.00">
 <p><label>Credit card number: <input type=text inputmode=numeric
 autocomplete=cc-number></label>
 <p><label>Expiry Date: <input type=month autocomplete=cc-exp></label>
 <p><input type=submit value="Continue...">
</form>
```

The **autofill field** keywords relate to each other as described in the table below. Each field name listed on a row of this table corresponds to the meaning given in the cell for that row in the column labeled "Meaning". Some fields correspond to subparts of other fields; for example, a credit card expiry date can be expressed as one field giving both the month and year of expiry ("[cc-exp<sup>p538</sup>](#)"), or as two fields, one giving the month ("[cc-exp-month<sup>p538</sup>](#)") and one the year ("[cc-exp-year<sup>p538</sup>](#)"). In such cases, the names of the broader fields cover multiple rows, in which the narrower fields are defined.

**Note** *Generally, authors are encouraged to use the broader fields rather than the narrower fields, as the narrower fields tend to expose Western biases. For example, while it is common in some Western cultures to have a given name and a family name, in that order (and thus often referred to as a first name and a surname), many cultures put the family name first and the given name second, and many others simply have one name (a mononym). Having a single field is therefore more flexible.*

Some fields are only appropriate for certain form controls. An [autofill field<sup>p537</sup>](#) name is **inappropriate for a control** if the control does not belong to the group listed for that [autofill field<sup>p537</sup>](#) in the fifth column of the first row describing that [autofill field<sup>p537</sup>](#) in the table below. What controls fall into each group is described below the table.

Field name	Meaning	Canonical Format	Canonical Format Example	Control group
"name"	Full name	Free-form text, no newlines	Sir Timothy John Berners-Lee, OM, KBE, FRS, FREng, FRSA	<a href="#">Text<sup>p539</sup></a>
"honorific-prefix"	Prefix or title (e.g. "Mr.", "Ms.", "Dr.", "M <sup>lle</sup> re")	Free-form text, no newlines	Sir	<a href="#">Text<sup>p539</sup></a>
"given-name"	Given name (in some Western cultures, also known as the <i>first name</i> )	Free-form text, no newlines	Timothy	<a href="#">Text<sup>p539</sup></a>
"additional-name"	Additional names (in some Western cultures, also known as <i>middle names</i> , forenames other than the first name)	Free-form text, no newlines	John	<a href="#">Text<sup>p539</sup></a>
"family-name"	Family name (in some Western cultures, also known as the <i>last name</i> or <i>surname</i> )	Free-form text, no newlines	Berners-Lee	<a href="#">Text<sup>p539</sup></a>
"honorific-suffix"	Suffix (e.g. "Jr.", "B.Sc.", "MBASW", "II")	Free-form text, no newlines	OM, KBE, FRS, FREng, FRSA	<a href="#">Text<sup>p539</sup></a>
"nickname"	Nickname, screen name, handle: a typically short name used instead of the full name	Free-form text, no newlines	Tim	<a href="#">Text<sup>p539</sup></a>
"organization-title"	Job title (e.g. "Software Engineer", "Senior Vice President", "Deputy Managing Director")	Free-form text, no newlines	Professor	<a href="#">Text<sup>p539</sup></a>
"username"	A username	Free-form text, no newlines	timbl	<a href="#">Text<sup>p539</sup></a>

Field name	Meaning	Canonical Format	Canonical Format Example	Control group
"new-password"	A new password (e.g. when creating an account or changing a password)	Free-form text, no newlines	GUMFXbadyrS3	<a href="#">Password<sup>p539</sup></a>
"current-password"	The current password for the account identified by the <a href="#">username<sup>p537</sup></a> field (e.g. when logging in)	Free-form text, no newlines	qwerty	<a href="#">Password<sup>p539</sup></a>
"organization"	Company name corresponding to the person, address, or contact information in the other fields associated with this field	Free-form text, no newlines	World Wide Web Consortium	<a href="#">Text<sup>p539</sup></a>
"street-address"	Street address (multiple lines, newlines preserved)	Free-form text	32 Vassar Street MIT Room 32-G524	<a href="#">Multiline<sup>p539</sup></a>
"address-line1"	Street address (one line per field)	Free-form text, no newlines	32 Vassar Street	<a href="#">Text<sup>p539</sup></a>
"address-line2"		Free-form text, no newlines	MIT Room 32-G524	<a href="#">Text<sup>p539</sup></a>
"address-line3"		Free-form text, no newlines		<a href="#">Text<sup>p539</sup></a>
"address-level4"	The most fine-grained <a href="#">administrative level<sup>p540</sup></a> , in addresses with four administrative levels	Free-form text, no newlines		<a href="#">Text<sup>p539</sup></a>
"address-level3"	The <a href="#">third administrative level<sup>p540</sup></a> , in addresses with three or more administrative levels	Free-form text, no newlines		<a href="#">Text<sup>p539</sup></a>
"address-level2"	The <a href="#">second administrative level<sup>p540</sup></a> , in addresses with two or more administrative levels; in the countries with two administrative levels, this would typically be the city, town, village, or other locality within which the relevant street address is found	Free-form text, no newlines	Cambridge	<a href="#">Text<sup>p539</sup></a>
"address-level1"	The broadest <a href="#">administrative level<sup>p540</sup></a> in the address, i.e. the province within which the locality is found; for example, in the US, this would be the state; in Switzerland it would be the canton; in the UK, the post town	Free-form text, no newlines	MA	<a href="#">Text<sup>p539</sup></a>
"country"	Country code	Valid <a href="#">ISO 3166-1-alpha-2 country code [ISO3166]<sup>p1150</sup></a>	US	<a href="#">Text<sup>p539</sup></a>
"country-name"	Country name	Free-form text, no newlines; <a href="#">derived from country in some cases<sup>p545</sup></a>	US	<a href="#">Text<sup>p539</sup></a>
"postal-code"	Postal code, post code, ZIP code, CEDEX code (if CEDEX, append "CEDEX", and the <a href="#">arrondissement</a> , if relevant, to the <a href="#">address-level12<sup>p538</sup></a> field)	Free-form text, no newlines	02139	<a href="#">Text<sup>p539</sup></a>
"cc-name"	Full name as given on the payment instrument	Free-form text, no newlines	Tim Berners-Lee	<a href="#">Text<sup>p539</sup></a>
"cc-given-name"	Given name as given on the payment instrument (in some Western cultures, also known as the <i>first name</i> )	Free-form text, no newlines	Tim	<a href="#">Text<sup>p539</sup></a>
"cc-additional-name"	Additional names given on the payment instrument (in some Western cultures, also known as <i>middle names</i> , forenames other than the first name)	Free-form text, no newlines		<a href="#">Text<sup>p539</sup></a>
"cc-family-name"	Family name given on the payment instrument (in some Western cultures, also known as the <i>last name</i> or <i>surname</i> )	Free-form text, no newlines	Berners-Lee	<a href="#">Text<sup>p539</sup></a>
"cc-number"	Code identifying the payment instrument (e.g. the credit card number)	<a href="#">ASCII digits<sup>p58</sup></a>	4114360123456785	<a href="#">Text<sup>p539</sup></a>
"cc-exp"	Expiration date of the payment instrument	<a href="#">Valid month string<sup>b67</sup></a>	2014-12	<a href="#">Month<sup>p540</sup></a>
"cc-exp-month"	Month component of the expiration date of the payment instrument	<a href="#">Valid integer<sup>b60</sup></a> in the range 1..12	12	<a href="#">Numeric<sup>p540</sup></a>
"cc-exp-year"	Year component of the expiration date of the payment instrument	<a href="#">Valid integer<sup>b60</sup></a> greater than zero	2014	<a href="#">Numeric<sup>p540</sup></a>
"cc-csc"	Security code for the payment instrument (also known as the card security code (CSC), card validation code (CVC), card verification value (CVV), signature panel code (SPC), credit card ID (CCID), etc)	<a href="#">ASCII digits<sup>p58</sup></a>	419	<a href="#">Text<sup>p539</sup></a>
"cc-type"	Type of payment instrument	Free-form text, no newlines	Visa	<a href="#">Text<sup>p539</sup></a>
"transaction-currency"	The currency that the user would prefer the transaction to use	ISO 4217 currency code <a href="#">[ISO4217]<sup>p1150</sup></a>	GBP	<a href="#">Text<sup>p539</sup></a>
"transaction-amount"	The amount that the user would like for the transaction (e.g. when entering a bid or sale price)	<a href="#">Valid floating-point number<sup>b61</sup></a>	401.00	<a href="#">Numeric<sup>p540</sup></a>
"language"	Preferred language	Valid BCP 47 language tag <a href="#">[BCP47]<sup>p1148</sup></a>	en	<a href="#">Text<sup>p539</sup></a>
"bday"	Birthday	<a href="#">Valid date string<sup>b67</sup></a>	1955-06-08	<a href="#">Date<sup>p540</sup></a>
"bday-day"	Day component of birthday	<a href="#">Valid integer<sup>b60</sup></a> in the range 1..31	8	<a href="#">Numeric<sup>p540</sup></a>

Field name	Meaning	Canonical Format	Canonical Format Example	Control group
" <b>bdy-month</b> "	Month component of birthday	Valid integer <sup>b60</sup> in the range 1..12	6	Numeric <sup>p540</sup>
" <b>bdy-year</b> "	Year component of birthday	Valid integer <sup>b60</sup> greater than zero	1955	Numeric <sup>p540</sup>
" <b>sex</b> "	Gender identity (e.g. Female, Fa'afafine)	Free-form text, no newlines	Male	Text <sup>p539</sup>
" <b>url</b> "	Home page or other Web page corresponding to the company, person, address, or contact information in the other fields associated with this field	Valid URL <sup>p81</sup>	http://www.w3.org/People/Berners-Lee/	URL <sup>p539</sup>
" <b>photo</b> "	Photograph, icon, or other image corresponding to the company, person, address, or contact information in the other fields associated with this field	Valid URL <sup>p81</sup>	http://www.w3.org/Press/Stock/Berners-Lee/2001-europaeum-eighth.jpg	URL <sup>p539</sup>
" <b>tel</b> "	Full telephone number, including country code	ASCII digits <sup>p58</sup> and U+0020 SPACE characters, prefixed by a U+002B PLUS SIGN character (+)	+1 617 253 5702	Tel <sup>p540</sup>
" <b>tel-country-code</b> "	Country code component of the telephone number	ASCII digits <sup>p58</sup> prefixed by a U+002B PLUS SIGN character (+)	+1	Text <sup>p539</sup>
" <b>tel-national</b> "	Telephone number without the country code component, with a country-internal prefix applied if applicable	ASCII digits <sup>p58</sup> and U+0020 SPACE characters	617 253 5702	Text <sup>p539</sup>
" <b>tel-area-code</b> "	Area code component of the telephone number, with a country-internal prefix applied if applicable	ASCII digits <sup>p58</sup>	617	Text <sup>p539</sup>
" <b>tel-local</b> "	Telephone number without the country code and area code components	ASCII digits <sup>p58</sup>	2535702	Text <sup>p539</sup>
" <b>tel-local-prefix</b> "	First part of the component of the telephone number that follows the area code, when that component is split into two components	ASCII digits <sup>p58</sup>	253	Text <sup>p539</sup>
" <b>tel-local-suffix</b> "	Second part of the component of the telephone number that follows the area code, when that component is split into two components	ASCII digits <sup>p58</sup>	5702	Text <sup>p539</sup>
" <b>tel-extension</b> "	Telephone number internal extension code	ASCII digits <sup>p58</sup>	1000	Text <sup>p539</sup>
" <b>email</b> "	E-mail address	Valid e-mail address <sup>p462</sup>	timbl@w3.org	E-mail <sup>p540</sup>
" <b>impp</b> "	URL representing an instant messaging protocol endpoint (for example, "aim:goim?screenname=example" or "xmpp:fred@example.net")	Valid URL <sup>p81</sup>	irc://example.org/timbl,isuser	URL <sup>p539</sup>

The groups correspond to controls as follows:

### Text

`input`<sup>p452</sup> elements with a `type`<sup>p454</sup> attribute in the `Hidden`<sup>p458</sup> state  
`input`<sup>p452</sup> elements with a `type`<sup>p454</sup> attribute in the `Text`<sup>p458</sup> state  
`input`<sup>p452</sup> elements with a `type`<sup>p454</sup> attribute in the `Search`<sup>p458</sup> state  
`textarea`<sup>b508</sup> elements  
`select`<sup>p498</sup> elements

### Multiline

`input`<sup>p452</sup> elements with a `type`<sup>p454</sup> attribute in the `Hidden`<sup>p458</sup> state  
`textarea`<sup>b508</sup> elements  
`select`<sup>p498</sup> elements

### Password

`input`<sup>p452</sup> elements with a `type`<sup>p454</sup> attribute in the `Hidden`<sup>p458</sup> state  
`input`<sup>p452</sup> elements with a `type`<sup>p454</sup> attribute in the `Text`<sup>p458</sup> state  
`input`<sup>p452</sup> elements with a `type`<sup>p454</sup> attribute in the `Search`<sup>p458</sup> state  
`input`<sup>p452</sup> elements with a `type`<sup>p454</sup> attribute in the `Password`<sup>p462</sup> state  
`textarea`<sup>b508</sup> elements  
`select`<sup>p498</sup> elements

### URL

`input`<sup>p452</sup> elements with a `type`<sup>p454</sup> attribute in the `Hidden`<sup>p458</sup> state  
`input`<sup>p452</sup> elements with a `type`<sup>p454</sup> attribute in the `Text`<sup>p458</sup> state

input<sup>p452</sup> elements with a type<sup>p454</sup> attribute in the Search<sup>p458</sup> state  
input<sup>p452</sup> elements with a type<sup>p454</sup> attribute in the URL<sup>p460</sup> state  
textarea<sup>b508</sup> elements  
select<sup>p498</sup> elements

#### E-mail

input<sup>p452</sup> elements with a type<sup>p454</sup> attribute in the Hidden<sup>p458</sup> state  
input<sup>p452</sup> elements with a type<sup>p454</sup> attribute in the Text<sup>p458</sup> state  
input<sup>p452</sup> elements with a type<sup>p454</sup> attribute in the Search<sup>p458</sup> state  
input<sup>p452</sup> elements with a type<sup>p454</sup> attribute in the E-mail<sup>p461</sup> state  
textarea<sup>b508</sup> elements  
select<sup>p498</sup> elements

#### Tel

input<sup>p452</sup> elements with a type<sup>p454</sup> attribute in the Hidden<sup>p458</sup> state  
input<sup>p452</sup> elements with a type<sup>p454</sup> attribute in the Text<sup>p458</sup> state  
input<sup>p452</sup> elements with a type<sup>p454</sup> attribute in the Search<sup>p458</sup> state  
input<sup>p452</sup> elements with a type<sup>p454</sup> attribute in the Telephone<sup>p459</sup> state  
textarea<sup>b508</sup> elements  
select<sup>p498</sup> elements

#### Numeric

input<sup>p452</sup> elements with a type<sup>p454</sup> attribute in the Hidden<sup>p458</sup> state  
input<sup>p452</sup> elements with a type<sup>p454</sup> attribute in the Text<sup>p458</sup> state  
input<sup>p452</sup> elements with a type<sup>p454</sup> attribute in the Search<sup>p458</sup> state  
input<sup>p452</sup> elements with a type<sup>p454</sup> attribute in the Number<sup>p469</sup> state  
textarea<sup>b508</sup> elements  
select<sup>p498</sup> elements

#### Month

input<sup>p452</sup> elements with a type<sup>p454</sup> attribute in the Hidden<sup>p458</sup> state  
input<sup>p452</sup> elements with a type<sup>p454</sup> attribute in the Text<sup>p458</sup> state  
input<sup>p452</sup> elements with a type<sup>p454</sup> attribute in the Search<sup>p458</sup> state  
input<sup>p452</sup> elements with a type<sup>p454</sup> attribute in the Month<sup>p465</sup> state  
textarea<sup>b508</sup> elements  
select<sup>p498</sup> elements

#### Date

input<sup>p452</sup> elements with a type<sup>p454</sup> attribute in the Hidden<sup>p458</sup> state  
input<sup>p452</sup> elements with a type<sup>p454</sup> attribute in the Text<sup>p458</sup> state  
input<sup>p452</sup> elements with a type<sup>p454</sup> attribute in the Search<sup>p458</sup> state  
input<sup>p452</sup> elements with a type<sup>p454</sup> attribute in the Date<sup>p464</sup> state  
textarea<sup>b508</sup> elements  
select<sup>p498</sup> elements

**Address levels:** The "address-level1<sup>p538</sup>" – "address-level4<sup>p538</sup>" fields are used to describe the locality of the street address. Different locales have different numbers of levels. For example, the US uses two levels (state and town), the UK uses one or two depending on the address (the post town, and in some cases the locality), and China can use three (province, city, district). The "address-level1<sup>p538</sup>" field represents the widest administrative division. Different locales order the fields in different ways; for example, in the US the town (level 2) precedes the state (level 1); while in Japan the prefecture (level 1) precedes the city (level 2) which precedes the district (level 3). Authors are encouraged to provide forms that are presented in a way that matches the country's conventions (hiding, showing, and rearranging fields accordingly as the user changes the country).

#### 4.10.19.8.2 Processing model

Each input<sup>p452</sup> element to which the autocomplete<sup>b535</sup> attribute applies<sup>p455</sup>, each select<sup>p498</sup> element, and each textarea<sup>b508</sup> element, has an autofill hint set, an autofill scope, an autofill field name, and an IDL-exposed autofill value.

The [autofill field name](#)<sup>p540</sup> specifies the specific kind of data expected in the field, e.g. "[street-address](#)<sup>p538</sup>" or "[cc-exp](#)<sup>p538</sup>".

The [autofill hint set](#)<sup>p540</sup> identifies what address or contact information type the user agent is to look at, e.g. "[shipping](#)<sup>p535</sup> [fax](#)<sup>p536</sup>" or "[billing](#)<sup>p535</sup>".

The [autofill scope](#)<sup>p540</sup> identifies the group of fields whose information concerns the same subject, and consists of the [autofill hint set](#)<sup>p540</sup> with, if applicable, the "section-\*" prefix, e.g. "billing", "section-parent shipping", or "section-child shipping home".

These values are defined as the result of running the following algorithm:

1. If the element has no [autocomplete](#)<sup>p535</sup> attribute, then jump to the step labeled *default*.
2. Let *tokens* be the result of [splitting the attribute's value on spaces](#)<sup>p80</sup>.
3. If *tokens* is empty, then jump to the step labeled *default*.
4. Let *index* be the index of the last token in *tokens*.
5. If the *index*th token in *tokens* is not an [ASCII case-insensitive](#)<sup>p58</sup> match for one of the tokens given in the first column of the following table, or if the number of tokens in *tokens* is greater than the maximum number given in the cell in the second column of that token's row, then jump to the step labeled *default*. Otherwise, let *field* be the string given in the cell of the first column of the matching row, and let *category* be the value of the cell in the third column of that same row.

Token	Maximum number of tokens	Category
" <a href="#">off</a> <sup>p536</sup> "	1	Off
" <a href="#">on</a> <sup>p537</sup> "	1	Automatic

6. If *category* is Off or Automatic but the element's autocomplete<sup>p535</sup> attribute is wearing the autofill anchor mantle<sup>p535</sup>, then jump to the step labeled *default*.
7. If *category* is Off, let the element's autofill field name<sup>p540</sup> be the string "off", let its autofill hint set<sup>p540</sup> be empty, and let its IDL-exposed autofill value<sup>p540</sup> be the string "off". Then, abort these steps.
8. If *category* is Automatic, let the element's autofill field name<sup>p540</sup> be the string "on", let its autofill hint set<sup>p540</sup> be empty, and let its IDL-exposed autofill value<sup>p540</sup> be the string "on". Then, abort these steps.
9. Let *scope tokens* be an empty list.
10. Let *hint tokens* be an empty set.
11. Let *IDL value* have the same value as *field*.
12. If the *index*th token in *tokens* is the first entry, then skip to the step labeled *done*.
13. Decrement *index* by one.
14. If *category* is Contact and the *index*th token in *tokens* is an ASCII case-insensitive<sup>p58</sup> match for one of the strings in the following list, then run the substeps that follow:
  - o "home<sup>p536</sup>"
  - o "work<sup>p536</sup>"
  - o "mobile<sup>p536</sup>"
  - o "fax<sup>p536</sup>"
  - o "pager<sup>p536</sup>"

The substeps are:

1. Let *contact* be the matching string from the list above.
2. Insert *contact* at the start of *scope tokens*.
3. Add *contact* to *hint tokens*.
4. Let *IDL value* be the concatenation of *contact*, a U+0020 SPACE character, and the previous value of *IDL value* (which at this point will always be *field*).

5. If the *index*th entry in *tokens* is the first entry, then skip to the step labeled *done*.
  6. Decrement *index* by one.
15. If the *index*th token in *tokens* is an [ASCII case-insensitive<sup>p58</sup>](#) match for one of the strings in the following list, then run the substeps that follow:
- "shipping<sup>p535</sup>"
  - "billing<sup>p535</sup>"
- The substeps are:
1. Let *mode* be the matching string from the list above.
  2. Insert *mode* at the start of *scope tokens*.
  3. Add *mode* to *hint tokens*.
  4. Let *IDL value* be the concatenation of *mode*, a U+0020 SPACE character, and the previous value of *IDL value* (which at this point will either be *field* or the concatenation of *contact*, a space, and *field*).
  5. If the *index*th entry in *tokens* is the first entry, then skip to the step labeled *done*.
  6. Decrement *index* by one.
16. If the *index*th entry in *tokens* is not the first entry, then jump to the step labeled *default*.
17. If the first eight characters of the *index*th token in *tokens* are not an [ASCII case-insensitive<sup>p58</sup>](#) match for the string "[section-](#)<sup>p535</sup>", then jump to the step labeled *default*.
18. Let *section* be the *index*th token in *tokens*, [converted to ASCII lowercase<sup>p58</sup>](#).
19. Insert *section* at the start of *scope tokens*.
20. Let *IDL value* be the concatenation of *section*, a U+0020 SPACE character, and the previous value of *IDL value*.
21. *Done*: Let the element's [autofill hint set<sup>p540</sup>](#) be *hint tokens*.
22. Let the element's [autofill scope<sup>p540</sup>](#) be *scope tokens*.
23. Let the element's [autofill field name<sup>p540</sup>](#) be *field*.
24. Let the element's [IDL-exposed autofill value<sup>p540</sup>](#) be *IDL value*.
25. Abort these steps.
26. *Default*: Let the element's [IDL-exposed autofill value<sup>p540</sup>](#) be the empty string, and its [autofill hint set<sup>p540</sup>](#) and [autofill scope<sup>p540</sup>](#) be empty.
27. If the element's [autocomplete<sup>p535</sup>](#) attribute is wearing the [autofill anchor mantle<sup>p535</sup>](#), then let the element's [autofill field name<sup>p540</sup>](#) be the empty string and abort these steps.
28. Let *form* be the element's [form owner<sup>p527</sup>](#), if any, or null otherwise.
29. If *form* is not null and *form*'s [autocomplete<sup>p448</sup>](#) attribute is in the [off<sup>p448</sup>](#) state, then let the element's [autofill field name<sup>p540</sup>](#) be "[off<sup>p536</sup>](#)".
- Otherwise, let the element's [autofill field name<sup>p540</sup>](#) be "[on<sup>p537</sup>](#)".

For the purposes of autofill, a **control's data** depends on the kind of control:

An [input<sup>p452</sup>](#) element with its [type<sup>p454</sup>](#) attribute in the [E-mail<sup>p461</sup>](#) state and with the [multiple<sup>p485</sup>](#) attribute specified  
The element's [values<sup>p527</sup>](#).

Any other [input<sup>p452</sup>](#) element

A [textarea<sup>p508</sup>](#) element  
The element's [value<sup>p527</sup>](#).

A [select<sup>p498</sup>](#) element with its [multiple<sup>p499</sup>](#) attribute specified

The [option<sup>p505</sup>](#) elements in the [select<sup>p498</sup>](#) element's [list of options<sup>p499</sup>](#) that have their [selectedness<sup>p507</sup>](#) set to true.

## Any other select<sup>p498</sup> element

The option<sup>p505</sup> element in the select<sup>p498</sup> element's list of options<sup>p499</sup> that has its selectedness<sup>p507</sup> set to true.

How to process the autocomplete hint set<sup>p540</sup>, autocomplete scope<sup>p540</sup>, and autocomplete field name<sup>p540</sup> depends on the mantle that the autocomplete<sup>p535</sup> attribute is wearing.

### ↪ When wearing the autocomplete expectation mantle<sup>p535</sup>...

When an element's autocomplete field name<sup>p540</sup> is "off<sup>p536</sup>", the user agent should not remember the control's data<sup>p543</sup>, and should not offer past values to the user.

**Note** *In addition, when an element's autocomplete field name<sup>p540</sup> is "off<sup>p536</sup>", values are reset<sup>p802</sup> when traversing the history<sup>p801</sup>.*

**Example** Banks frequently do not want UAs to prefill login information:

```
<p><label>Account: <input type="text" name="ac" autocomplete="off"></label></p>
<p><label>PIN: <input type="password" name="pin" autocomplete="off"></label></p>
```

When an element's autocomplete field name<sup>p540</sup> is *not* "off<sup>p536</sup>", the user agent may store the control's data<sup>p543</sup>, and may offer previously stored values to the user.

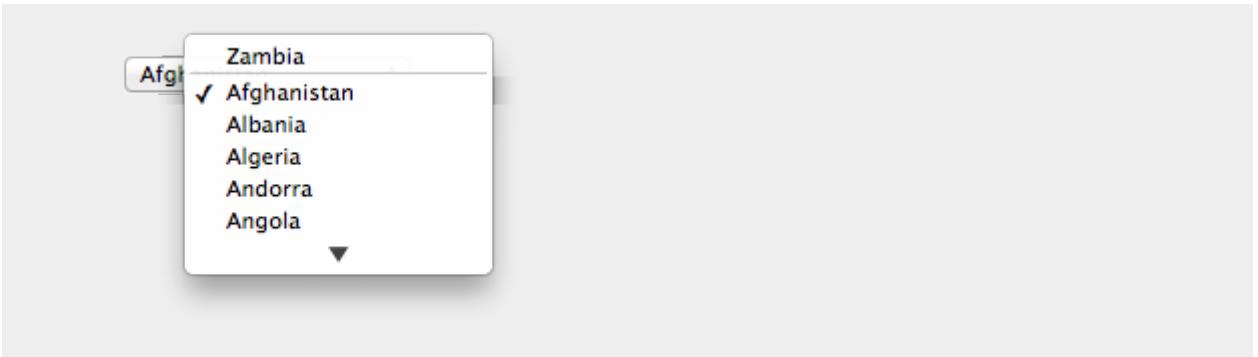

**Example** For example, suppose a user visits a page with this control:

```
<select name="country">
 <option>Afghanistan
 <option>Albania
 <option>Algeria
 <option>Andorra
 <option>Angola
 <option>Antigua and Barbuda
 <option>Argentina
 <option>Armenia
 <!-- ... -->
 <option>Yemen
 <option>Zambia
 <option>Zimbabwe
</select>
```

This might render as follows:

Suppose that on the first visit to this page, the user selects "Zambia". On the second visit, the user agent could duplicate the entry for Zambia at the top of the list, so that the interface instead looks like this:

When the [autofill field name](#)<sup>p540</sup> is "[on](#)"<sup>p537</sup>, the user agent should attempt to use heuristics to determine the most appropriate values to offer the user, e.g. based on the element's [name](#)<sup>p529</sup> value, the position of the element in the document's DOM, what other fields exist in the form, and so forth.

When the [autofill field name](#)<sup>p540</sup> is one of the names of the [autofill fields](#)<sup>p537</sup> described above, the user agent should provide suggestions that match the meaning of the field name as given in the table earlier in this section. The [autofill hint set](#)<sup>p540</sup> should be used to select amongst multiple possible suggestions.

**Example** For example, if a user once entered one address into fields that used the "[shipping](#)"<sup>p535</sup> keyword, and another address into fields that used the "[billing](#)"<sup>p535</sup> keyword, then in subsequent forms only the first address would be suggested for form controls whose [autofill hint set](#)<sup>p540</sup> contains the keyword "[shipping](#)". Both addresses might be suggested, however, for address-related form controls whose [autofill hint set](#)<sup>p540</sup> does not contain either keyword.

#### ↳ When wearing the [autofill anchor mantle](#)<sup>p535</sup>...

When the [autofill field name](#)<sup>p540</sup> is not the empty string, then the user agent must act as if the user had specified the [control's data](#)<sup>p543</sup> for the given [autofill hint set](#)<sup>p540</sup>, [autofill scope](#)<sup>p540</sup>, and [autofill field name](#)<sup>p540</sup> combination.

When the user agent **autofills form controls**, elements with the same [form owner](#)<sup>p527</sup> and the same [autofill scope](#)<sup>p540</sup> must use data relating to the same person, address, payment instrument, and contact details. When a user agent autofills "[country](#)"<sup>p538</sup> and "[country-name](#)"<sup>p538</sup> fields with the same [form owner](#)<sup>p527</sup> and [autofill scope](#)<sup>p540</sup>, and the user agent has a value for the [country](#)<sup>p538</sup> field(s), then the "[country-name](#)"<sup>p538</sup> field(s) must be filled using a human-readable name for the same country. When a user agent fills in multiple fields at once, all fields with the same [autofill field name](#)<sup>p540</sup>, [form owner](#)<sup>p527</sup> and [autofill scope](#)<sup>p540</sup> must be filled with the same value.

**Example** Suppose a user agent knows of two phone numbers, +1 555 123 1234 and +1 555 666 7777. It would not be conforming for the user agent to fill a field with `autocomplete="shipping tel-local-prefix"` with the value "123" and another field in the same form with `autocomplete="shipping tel-local-suffix"` with the value "7777". The only valid prefilled values given the aforementioned information would be "123" and "1234", or "666" and "7777", respectively.

**Example** Similarly, if a form for some reason contained both a "[cc-exp](#)"<sup>p538</sup> field and a "[cc-exp-month](#)"<sup>p538</sup> field, and the user agent prefilled the form, then the month component of the former would have to match the latter.

**Example** This requirement interacts with the [autofill anchor mantle](#)<sup>p535</sup> also. Consider the following markup snippet:

```
<form>
 <input type=hidden autocomplete="nickname" value="TreePlate">
 <input type=text autocomplete="nickname">
</form>
```

The only value that a conforming user agent could suggest in the text field is "TreePlate", the value given by the hidden [input](#)<sup>p452</sup> element.

The "`section-*`" tokens in the [autofill scope](#)<sup>p540</sup> are opaque; user agents must not attempt to derive meaning from the precise values of these tokens.

**Example** For example, it would not be conforming if the user agent decided that it should offer the address it knows to be the user's daughter's address for "`section-child`" and the addresses it knows to be the user's spouses' addresses for "`section-spouse`".

The autocompletion mechanism must be implemented by the user agent acting as if the user had modified the [control's data](#)<sup>p543</sup>, and must be done at a time where the element is [mutable](#)<sup>p527</sup> (e.g. just after the element has been inserted into the document, or when the user agent [stops parsing](#)<sup>p1033</sup>). User agents must only prefill controls using values that the user could have entered.

**Example** For example, if a [select](#)<sup>p498</sup> element only has [option](#)<sup>p505</sup> elements with values "Steve" and "Rebecca", "Jay", and "Bob", and has an [autofill field name](#)<sup>p540</sup> "[given-name](#)<sup>p537</sup>", but the user agent's only idea for what to prefill the field with is "Evan", then the user agent cannot prefill the field. It would not be conforming to somehow set the [select](#)<sup>p498</sup> element to the value "Evan", since the user could not have done so themselves.

A user agent prefilling a form control's [value](#)<sup>p527</sup> must not cause that control to [suffer from a type mismatch](#)<sup>p553</sup>, [suffer from being too long](#)<sup>p553</sup>, [suffer from being too short](#)<sup>p553</sup>, [suffer from an underflow](#)<sup>p553</sup>, [suffer from an overflow](#)<sup>p553</sup>, or [suffer from a step mismatch](#)<sup>p553</sup>. Except when [autofilling](#)<sup>p545</sup> for [requestAutocomplete\(\)](#)<sup>p547</sup>, a user agent prefilling a form control's [value](#)<sup>p527</sup> must not cause that control to [suffer from a pattern mismatch](#)<sup>p553</sup> either. Where possible given the control's constraints, user agents must use the format given as canonical in the aforementioned table. Where it's not possible for the canonical format to be used, user agents should use heuristics to attempt to convert values so that they can be used.

**Example** For example, if the user agent knows that the user's middle name is "Ines", and attempts to prefill a form control that looks like this:

```
<input name=middle-initial maxlength=1 autocomplete="additional-name">
...then the user agent could convert "Ines" to "I" and prefill it that way.
```

**Example** A more elaborate example would be with month values. If the user agent knows that the user's birthday is the 27th of July 2012, then it might try to prefill all of the following controls with slightly different values, all driven from this information:

<code>&lt;input name=b type=month autocomplete="bday"&gt;</code>	2012-07	The day is dropped since the <a href="#">Month</a> <sup>p465</sup> state only accepts a month/year combination.
<code>&lt;select name=c autocomplete="bday"&gt;   &lt;option&gt;Jan   &lt;option&gt;Feb   ...   &lt;option&gt;Jul   &lt;option&gt;Aug   ... &lt;/select&gt;</code>	July	The user agent picks the month from the listed options, either by noticing there are twelve options and picking the 7th, or by recognising that one of the strings (three characters "Jul" followed by a newline and a space) is a close match for the name of the month (July) in one of the user agent's supported languages, or through some other similar mechanism.
<code>&lt;input name=a type=number min=1 max=12 autocomplete="bday-month"&gt;</code>	7	User agent converts "July" to a month number in the range 1..12, like the field.
<code>&lt;input name=a type=number min=0 max=11 autocomplete="bday-month"&gt;</code>	6	User agent converts "July" to a month number in the range 0..11, like the field.
<code>&lt;input name=a type=number min=1 max=11 autocomplete="bday-month"&gt;</code>		User agent doesn't fill in the field, since it can't make a good guess as to what the form expects.

A user agent may allow the user to override an element's [autofill field name](#)<sup>p540</sup>, e.g. to change it from "[off](#)<sup>p536</sup>" to "[on](#)<sup>p537</sup>" to allow values to be remembered and prefilled despite the page author's objections, or to always "[off](#)<sup>p536</sup>", never remembering values.

More specifically, user agents may in particular consider replacing the [autofill field name](#)<sup>p540</sup> of form controls that match the description given in the first column of the following table, when their [autofill field name](#)<sup>p540</sup> is either "[on](#)<sup>p537</sup>" or "[off](#)<sup>p536</sup>", with the value given in the second cell of that row. If this table is used, the replacements must be done in [tree order](#)<sup>p42</sup>, since all but the first row references the [autofill field name](#)<sup>p540</sup> of earlier elements. When the descriptions below refer to form controls being preceded or followed by others, they mean in the list of listed elements that share the same [form owner](#)<sup>p527</sup>.

Form control	New <a href="#">autocomplete field name</a> <sup>p540</sup>
an <a href="#"><code>input</code></a> <sup>p452</sup> element whose <a href="#"><code>type</code></a> <sup>p454</sup> attribute is in the <a href="#">Text</a> <sup>p458</sup> state that is followed by an <a href="#"><code>input</code></a> <sup>p452</sup> element whose <a href="#"><code>type</code></a> <sup>p454</sup> attribute is in the <a href="#">Password</a> <sup>p462</sup> state	" <a href="#">username</a> <sup>p537</sup> "
an <a href="#"><code>input</code></a> <sup>p452</sup> element whose <a href="#"><code>type</code></a> <sup>p454</sup> attribute is in the <a href="#">Password</a> <sup>p462</sup> state that is preceded by an <a href="#"><code>input</code></a> <sup>p452</sup> element whose <a href="#">autocomplete field name</a> <sup>p540</sup> is " <a href="#">username</a> <sup>p537</sup> "	" <a href="#">current-password</a> <sup>p538</sup> "
an <a href="#"><code>input</code></a> <sup>p452</sup> element whose <a href="#"><code>type</code></a> <sup>p454</sup> attribute is in the <a href="#">Password</a> <sup>p462</sup> state that is preceded by an <a href="#"><code>input</code></a> <sup>p452</sup> element whose <a href="#">autocomplete field name</a> <sup>p540</sup> is " <a href="#">current-password</a> <sup>p538</sup> "	" <a href="#">new-password</a> <sup>p538</sup> "
an <a href="#"><code>input</code></a> <sup>p452</sup> element whose <a href="#"><code>type</code></a> <sup>p454</sup> attribute is in the <a href="#">Password</a> <sup>p462</sup> state that is preceded by an <a href="#"><code>input</code></a> <sup>p452</sup> element whose <a href="#">autocomplete field name</a> <sup>p540</sup> is " <a href="#">new-password</a> <sup>p538</sup> "	" <a href="#">new-password</a> <sup>p538</sup> "

The [autocomplete](#) IDL attribute, on getting, must return the element's [IDL-exposed autofill value](#)<sup>p540</sup>, and on setting, must [reflect](#)<sup>p88</sup> the content attribute of the same name.

#### 4.10.19.8.3 User interface for bulk autofill

When the [requestAutocomplete\(\)](#) method on a [`form`](#)<sup>p447</sup> element is invoked, the user agent must run the following steps:

1. Let *form* be the element on which the method was invoked.
2. If any of the following conditions are met, then [queue a task](#)<sup>p835</sup> to [fail the autofill request](#)<sup>p548</sup> on *form* with the reason "[disabled](#)<sup>p549</sup>", and abort these steps:
  - the algorithm is not [allowed to show a popup](#)<sup>p766</sup>
  - *form*'s [node document](#) is not [fully active](#)<sup>p763</sup>
  - *form*'s [autocomplete](#)<sup>p448</sup> attribute is in the [off](#)<sup>p448</sup> state
  - the user has disabled this feature for this *form*'s [node document](#)'s [origin](#)<sup>p776</sup>
  - the user agent does not support this *form*'s fields (e.g. the form has different fields whose [autocomplete scope](#)<sup>p540</sup> use different "section-\*" tokens)
  - the *form* was obtained via unencrypted channels and the user agent does not support autofill in such situations
  - another instance of this algorithm is already being run for *form*
3. Let *pending Autofills* be an initially empty list of [submittable elements](#)<sup>p447</sup>, each annotated with a string known as the *original autocomplete value*.
4. For each element that matches the following criteria, add the element to *pending Autofills*, with the *original autocomplete value* annotation being the value of the element's [autocomplete](#)<sup>p535</sup> attribute:
  - the element's [form owner](#)<sup>p527</sup> is *form*
  - the element is [mutable](#)<sup>p527</sup>
  - the element is an [`input`](#)<sup>p452</sup> element to which the [autocomplete](#)<sup>p535</sup> attribute currently [applies](#)<sup>p455</sup>, or, the element is a [`textarea`](#)<sup>p508</sup> element, or, the element is a [`select`](#)<sup>p498</sup> element
  - the element's [autocomplete](#)<sup>p535</sup> attribute is wearing the [autofill expectation mantle](#)<sup>p535</sup>
  - the element's [autocomplete](#)<sup>p540</sup> is neither "[off](#)<sup>p536</sup>" nor "[on](#)<sup>p537</sup>"
5. Return, but continue running these steps [in parallel](#)<sup>p41</sup>.
6. Provide an interface for the user to efficiently fill in some or all of the fields listed in *pending Autofills*. Await the user's input. The user agent may include additional (immutable) information, e.g. [data](#)<sup>p543</sup> obtained from elements with an [autocomplete](#)<sup>p535</sup> attribute wearing the [autofill anchor mantle](#)<sup>p535</sup>.
7. [Queue a task](#)<sup>p835</sup> to run the following steps:

- If any of the following conditions are met, then [fail the autofill request](#)<sup>p548</sup> on *form* with the reason "[disabled](#)<sup>p549</sup>", and abort these steps:
  - form* is no longer [in a Document](#)<sup>p42</sup>
  - form's node document* is no longer [fully active](#)<sup>p763</sup>
  - form's autocomplete*<sup>p448</sup> attribute is now in the [off](#)<sup>p448</sup> state

**Note** Again, user agents are encouraged to log the precise cause in a developer console, to aid debugging.

- If the user canceled the operation, [fail the autofill request](#)<sup>p548</sup> on *form* with the reason "[cancel](#)<sup>p549</sup>", and abort these steps.
- For each element in *pending autfills*, run the following steps:

- Let *candidate* be the element in question.
- Let *old autocomplete value* be the *original autocomplete value* annotation associated with *candidate* in *pending autfills*.
- If all of the following conditions are met, then [autofill](#)<sup>p545</sup> *candidate*:
  - candidate's form owner*<sup>p527</sup> is *form*
  - candidate* is still [mutable](#)<sup>p527</sup>
  - candidate* is an [input](#)<sup>p452</sup> element to which the [autocomplete](#)<sup>p535</sup> attribute still [applies](#)<sup>p455</sup>, or, *candidate* is a [textarea](#)<sup>p508</sup> element, or, *candidate* is a [select](#)<sup>p498</sup> element
  - the element's [autocomplete](#)<sup>p535</sup> attribute is still wearing the [autofill expectation mantle](#)<sup>p535</sup>
  - candidate's autofill field name*<sup>p540</sup> is still equal to *old autocomplete value*
  - the user provided a value to autofill *candidate*

- [Statically validate the constraints](#)<sup>p554</sup> of *form*. If the result was negative, then [fail the autofill request](#)<sup>p548</sup> on *form* with the reason "[invalid](#)<sup>p549</sup>", and abort these steps.

**Note** [Statically validating the constraints](#)<sup>p554</sup> of a [form](#)<sup>p447</sup> involves firing [invalid](#)<sup>p1144</sup> events to each control that does not [satisfy its constraints](#)<sup>p553</sup>.

- [Fire a simple event](#)<sup>p846</sup> that bubbles named [autocomplete](#)<sup>p1143</sup> at *form*.

When the user agent is required to [fail the autofill request](#) on a [form](#)<sup>p447</sup> element *target* with a reason *reason*, the user agent must dispatch an event that uses the [AutocompleteErrorEvent](#)<sup>p548</sup> interface, with the event type [autocompleteerror](#), which bubbles, is not cancelable, has no default action, has its [reason](#)<sup>p549</sup> attribute set to *reason*, and which is [trusted](#)<sup>p43</sup>, at *target*.

The [task source](#)<sup>p835</sup> for the [tasks](#)<sup>p834</sup> mentioned in this section is the [DOM manipulation task source](#)<sup>p838</sup>.

#### 4.10.19.8.4 The [AutocompleteErrorEvent](#)<sup>p548</sup> interface

```
IDL
enum AutocompleteErrorReason { "" /* empty string */, "cancel", "disabled", "invalid" };

[Constructor(DOMString type, optional AutocompleteErrorEventInit eventInitDict)]
interface AutocompleteErrorEvent : Event {
 readonly attribute AutocompleteErrorReason reason;
};

dictionary AutocompleteErrorEventInit : EventInit {
 AutocompleteErrorReason reason;
};
```

**Note**

`event.reason`<sup>p549</sup>

For the `autocompleteerror`<sup>p1143</sup> event, returns the general reason for the failure of the `requestAutocomplete()`<sup>p547</sup> method, from the list below.

The defined reason codes are:

**"" (the empty string)**

Reason is unknown.

**"cancel"**

The user canceled the autofill interface.

**"disabled"**

The autofill interface is disabled for this form.

There are many reasons why this might be the case; the precise reason is not given, to protect the user's privacy. Amongst these reasons are such factors as:

- The page being delivered over an unencrypted connection (susceptible to man-in-the-middle attacks), when the user agent does not want to risk the user's information being provided to an attacker.
- The form having a combination of fields for which the user agent does not have a dedicated autofill interface.
- The form's `autocomplete`<sup>p448</sup> attribute being in the `off`<sup>p448</sup> state.
- The user having disabled the feature.

**"invalid"**

The fields have been prefilled, but at least one of the controls in the form does not [satisfy its constraints](#)<sup>p553</sup>.

The `reason` attribute must return the value it was initialised to. When the object is created, this attribute must be initialised to the `empty string`<sup>p549</sup>. It represents the context information for the event.

#### 4.10.20 APIs for the text field selections

The `input`<sup>p452</sup> and `textarea`<sup>p508</sup> elements define the following members in their DOM interfaces for handling their selection:

**IDL**

```
void select();
attribute unsigned long selectionStart;
attribute unsigned long selectionEnd;
attribute DOMString selectionDirection;
void setRangeText(DOMString replacement);
void setRangeText(DOMString replacement, unsigned long start, unsigned long end, optional
SelectionMode selectionMode = "preserve");
void setSelectionRange(unsigned long start, unsigned long end, optional DOMString direction =
"preserve");
```

The `setRangeText`<sup>p551</sup> method uses the following enumeration:

**IDL**

```
enum SelectionMode {
 "select",
 "start",
 "end",
 "preserve", // default
};
```

Spec bugs: [27701](#)

These methods and attributes expose and control the selection of `input`<sup>p452</sup> and `textarea`<sup>p508</sup> text fields.

**Note**

`element.selectp551()`

Selects everything in the text field.

`element.selectionStartp551 [= value]`

Returns the offset to the start of the selection.

Can be set, to change the start of the selection.

`element.selectionEndp551 [= value]`

Returns the offset to the end of the selection.

Can be set, to change the end of the selection.

`element.selectionDirectionp551 [= value]`

Returns the current direction of the selection.

Can be set, to change the direction of the selection.

The possible values are "forward", "backward", and "none".

`element.setSelectionRangep551(start, end [, direction])`

Changes the selection to cover the given substring in the given direction. If the direction is omitted, it will be reset to be the platform default (none or forward).

`element.setRangeTextp551(replacement [, start, end [, selectionMode]])`

Replaces a range of text with the new text. If the `start` and `end` arguments are not provided, the range is assumed to be the selection.

The final argument determines how the selection should be set after the text has been replaced. The possible values are:

"select<sup>p552</sup>"

Selects the newly inserted text.

"start<sup>p552</sup>"

Moves the selection to just before the inserted text.

"end<sup>p552</sup>"

Moves the selection to just after the selected text.

"preserve<sup>p552</sup>"

Attempts to preserve the selection. This is the default.

For `inputp452` elements, calling these methods while they `don't applyp455`, and getting or setting these attributes while they `don't applyp455`, must throw an `InvalidStateErrorp50` exception. Otherwise, they must act as described below.

For `inputp452` elements, these methods and attributes must operate on the element's `valuep527`. For `textareap508` elements, these methods and attributes must operate on the element's `raw valuep509`.

Where possible, user interface features for changing the text selection in `inputp452` and `textareap508` elements must be implemented in terms of the DOM API described in this section, so that, e.g., all the same events fire.

The selections of `inputp452` and `textareap508` elements have a `direction`, which is either `forward`, `backward`, or `none`. This direction is set when the user manipulates the selection. The exact meaning of the selection direction depends on the platform.

**Note**

On Windows, the `direction` indicates the position of the caret relative to the selection: a forward selection has the caret at the end of the selection and a backward selection has the caret at the start of the selection. Windows has no none direction. On Mac, the `direction` indicates which end of the selection is affected when the user adjusts the size of the selection using the arrow keys with the Shift modifier: the forward direction means the end of the selection is modified, and the backwards direction means the start of the selection is modified. The none direction is the default on Mac, it indicates that no particular direction has yet been selected. The user sets the direction implicitly when first adjusting the selection, based on which directional arrow key was used.

The `select()` method must cause the contents of the text field to be fully selected, with the selection direction being `none`, if the platform supports selections with the direction `none`, or otherwise `forward`. The user agent must then [queue a task<sup>p835</sup>](#) to [fire a simple event<sup>p846</sup>](#) that bubbles named `selectp1145` at the element, using the [user interaction task source<sup>p838</sup>](#) as the task source.

In the case of [input<sup>p452</sup>](#) elements, if the control has no text field, then the method must do nothing.

**Example** For instance, in a user agent where `<input type="color">p474` is rendered as a colour well with a picker, as opposed to a text field accepting a hexadecimal colour code, there would be no text field, and thus nothing to select, and thus calls to the method are ignored.

The `selectionStart` attribute must, on getting, return the offset (in logical order) to the character that immediately follows the start of the selection. If there is no selection, then it must return the offset (in logical order) to the character that immediately follows the text entry cursor.

On setting, it must act as if the `setSelectionRange()p551` method had been called, with the new value as the first argument; the current value of the `selectionEndp551` attribute as the second argument, unless the current value of the `selectionEndp551` is less than the new value, in which case the second argument must also be the new value; and the current value of the `selectionDirectionp551` as the third argument.

The `selectionEnd` attribute must, on getting, return the offset (in logical order) to the character that immediately follows the end of the selection. If there is no selection, then it must return the offset (in logical order) to the character that immediately follows the text entry cursor.

On setting, it must act as if the `setSelectionRange()p551` method had been called, with the current value of the `selectionStartp551` attribute as the first argument, the new value as the second argument, and the current value of the `selectionDirectionp551` as the third argument.

The `selectionDirection` attribute must, on getting, return the string corresponding to the current selection direction: if the direction is `forward`, "forward"; if the direction is `backward`, "backward"; and otherwise, "none".

On setting, it must act as if the `setSelectionRange()p551` method had been called, with the current value of the `selectionStartp551` attribute as the first argument, the current value of the `selectionEndp551` attribute as the second argument, and the new value as the third argument.

The `setSelectionRange(start, end, direction)` method must set the selection of the text field to the sequence of characters starting with the character at the `start`th position (in logical order) and ending with the character at the `(end-1)`th position. Arguments greater than the length of the value of the text field must be treated as pointing at the end of the text field. If `end` is less than or equal to `start` then the start of the selection and the end of the selection must both be placed immediately before the character with offset `end`. In UAs where there is no concept of an empty selection, this must set the cursor to be just before the character with offset `end`. The direction of the selection must be set to `backward` if `direction` is a [case-sensitive<sup>p568</sup>](#) match for the string "backward", `forward` if `direction` is a [case-sensitive<sup>p568</sup>](#) match for the string "forward" or if the platform does not support selections with the direction `none`, and `none` otherwise (including if the argument is omitted). The user agent must then [queue a task<sup>p835</sup>](#) to [fire a simple event<sup>p846</sup>](#) that bubbles named `selectp1145` at the element, using the [user interaction task source<sup>p838</sup>](#) as the task source.

The `setRangeText(replacement, start, end, selectMode)` method must run the following steps:

1. If the method has only one argument, then let `start` and `end` have the values of the `selectionStartp551` attribute and the `selectionEndp551` attribute respectively.  
Otherwise, let `start`, `end` have the values of the second and third arguments respectively.
2. If `start` is greater than `end`, then throw an [IndexSizeError<sup>p50</sup>](#) exception and abort these steps.
3. If `start` is greater than the length of the value of the text field, then set it to the length of the value of the text field.
4. If `end` is greater than the length of the value of the text field, then set it to the length of the value of the text field.
5. Let `selection start` be the current value of the `selectionStartp551` attribute.
6. Let `selection end` be the current value of the `selectionEndp551` attribute.
7. If `start` is less than `end`, delete the sequence of characters starting with the character at the `start`th position (in logical order) and ending with the character at the `(end-1)`th position.
8. Insert the value of the first argument into the text of the value of the text field, immediately before the `start`th character.
9. Let `new length` be the length of the value of the first argument.
10. Let `new end` be the sum of `start` and `new length`.
11. Run the appropriate set of substeps from the following list:

↪ If the fourth argument's value is "**select**"

Let *selection start* be *start*.

Let *selection end* be *new end*.

↪ If the fourth argument's value is "**start**"

Let *selection start* and *selection end* be *start*.

↪ If the fourth argument's value is "**end**"

Let *selection start* and *selection end* be *new end*.

↪ If the fourth argument's value is "**preserve**" (the default)

1. Let *old length* be *end* minus *start*.

2. Let *delta* be *new length* minus *old length*.

3. If *selection start* is greater than *end*, then increment it by *delta*. (If *delta* is negative, i.e. the new text is shorter than the old text, then this will *decrease* the value of *selection start*.)

Otherwise: if *selection start* is greater than *start*, then set it to *start*. (This snaps the start of the selection to the start of the new text if it was in the middle of the text that it replaced.)

4. If *selection end* is greater than *end*, then increment it by *delta* in the same way.

Otherwise: if *selection end* is greater than *start*, then set it to *new end*. (This snaps the end of the selection to the end of the new text if it was in the middle of the text that it replaced.)

12. Set the selection of the text field to the sequence of characters starting with the character at the *selection start*th position (in logical order) and ending with the character at the (*selection end*-1)th position. In UAs where there is no concept of an empty selection, this must set the cursor to be just before the character with offset *end*. The direction of the selection must be set to *forward* if the platform does not support selections with the direction *none*, and *none* otherwise.
13. Queue a task<sup>p835</sup> to fire a simple event<sup>p846</sup> that bubbles named **select**<sup>p1145</sup> at the element, using the user interaction task source<sup>p838</sup> as the task source.

All elements to which this API applies<sup>p455</sup> have either a selection or a text entry cursor position at all times (even for elements that are not being rendered<sup>p1058</sup>). User agents should follow platform conventions to determine their initial state.

Characters with no visible rendering, such as U+200D ZERO WIDTH JOINER, still count as characters. Thus, for instance, the selection can include just an invisible character, and the text insertion cursor can be placed to one side or another of such a character.

#### Example

To obtain the currently selected text, the following JavaScript suffices:

```
var selectionText = control.value.substring(control.selectionStart, control.selectionEnd);
...where control is the inputp452 or textareap508 element.
```

#### Example

To add some text at the start of a text control, while maintaining the text selection, the three attributes must be preserved:

```
var oldStart = control.selectionStart;
var oldEnd = control.selectionEnd;
var oldDirection = control.selectionDirection;
var prefix = "http://";
control.value = prefix + control.value;
control.setSelectionRange(oldStart + prefix.length, oldEnd + prefix.length, oldDirection);
```

...where control is the input<sup>p452</sup> or textarea<sup>p508</sup> element.

## 4.10.21 Constraints

### 4.10.21.1 Definitions

A [submittable element](#)<sup>p447</sup> is a **candidate for constraint validation** except when a condition has **barred the element from constraint validation**. (For example, an element is [barred from constraint validation](#)<sup>p553</sup> if it is an [object](#)<sup>p310</sup> element.)

An element can have a **custom validity error message** defined. Initially, an element must have its [custom validity error message](#)<sup>p553</sup> set to the empty string. When its value is not the empty string, the element is [suffering from a custom error](#)<sup>p553</sup>. It can be set using the [setCustomValidity\(\)](#)<sup>p555</sup> method. The user agent should use the [custom validity error message](#)<sup>p553</sup> when alerting the user to the problem with the control.

An element can be constrained in various ways. The following is the list of **validity states** that a form control can be in, making the control invalid for the purposes of constraint validation. (The definitions below are non-normative; other parts of this specification define more precisely when each state applies or does not.)

#### Suffering from being missing

When a control has no [value](#)<sup>p527</sup> but has a [required](#) attribute ([input](#)<sup>p452</sup> [required](#)<sup>p484</sup>, [textarea](#)<sup>p508</sup> [required](#)<sup>p511</sup>); or, in the case of an element in a [radio button group](#)<sup>p475</sup>, any of the other elements in the group has a [required](#)<sup>p484</sup> attribute; or, for [select](#) elements, none of the [option](#)<sup>p505</sup> elements have their [selectedness](#)<sup>p507</sup> set ([select](#)<sup>p498</sup> [required](#)<sup>p499</sup>).

#### Suffering from a type mismatch

When a control that allows arbitrary user input has a [value](#)<sup>p527</sup> that is not in the correct syntax ([E-mail](#)<sup>p461</sup>, [URL](#)<sup>p460</sup>).

#### Suffering from a pattern mismatch

When a control has a [value](#)<sup>p527</sup> that doesn't satisfy the [pattern](#)<sup>p486</sup> attribute.

#### Suffering from being too long

When a control has a [value](#)<sup>p527</sup> that is too long for the [form control maxlen attribute](#)<sup>p529</sup> ([input](#)<sup>p452</sup> [maxlength](#)<sup>p483</sup>, [textarea](#)<sup>p508</sup> [maxlength](#)<sup>p511</sup>).

#### Suffering from being too short

When a control has a [value](#)<sup>p527</sup> that is too short for the [form control minlength attribute](#)<sup>p530</sup> ([input](#)<sup>p452</sup> [minlength](#)<sup>p483</sup>, [textarea](#)<sup>p508</sup> [minlength](#)<sup>p511</sup>).

#### Suffering from an underflow

When a control has a [value](#)<sup>p527</sup> that is too low for the [min](#)<sup>p487</sup> attribute.

#### Suffering from an overflow

When a control has a [value](#)<sup>p527</sup> that is too high for the [max](#)<sup>p487</sup> attribute.

#### Suffering from a step mismatch

When a control has a [value](#)<sup>p527</sup> that doesn't fit the rules given by the [step](#)<sup>p488</sup> attribute.

#### Suffering from bad input

When a control has incomplete input and the user agent does not think the user ought to be able to submit the form in its current state.

#### Suffering from a custom error

When a control's [custom validity error message](#)<sup>p553</sup> (as set by the element's [setCustomValidity\(\)](#)<sup>p555</sup> method) is not the empty string.

Spec bugs: [25369](#)

**Note** An element can still suffer from these states even when the element is [disabled](#)<sup>p530</sup>, thus these states can be represented in the DOM even if validating the form during submission wouldn't indicate a problem to the user.

An element **satisfies its constraints** if it is not suffering from any of the above [validity states](#)<sup>p553</sup>.

⋮

#### 4.10.21.2 Constraint validation

When the user agent is required to **statically validate the constraints** of [form<sup>p447</sup>](#) element *form*, it must run the following steps, which return either a *positive* result (all the controls in the form are valid) or a *negative* result (there are invalid controls) along with a (possibly empty) list of elements that are invalid and for which no script has claimed responsibility:

1. Let *controls* be a list of all the [submittable elements<sup>p447</sup>](#) whose [form owner<sup>p527</sup>](#) is *form*, in [tree order<sup>p42</sup>](#).
2. Let *invalid controls* be an initially empty list of elements.
3. For each element *field* in *controls*, in [tree order<sup>p42</sup>](#), run the following substeps:
  1. If *field* is not a [candidate for constraint validation<sup>p553</sup>](#), then move on to the next element.
  2. Otherwise, if *field* [satisfies its constraints<sup>p553</sup>](#), then move on to the next element.
  3. Otherwise, add *field* to *invalid controls*.
4. If *invalid controls* is empty, then return a *positive* result and abort these steps.
5. Let *unhandled invalid controls* be an initially empty list of elements.
6. For each element *field* in *invalid controls*, if any, in [tree order<sup>p42</sup>](#), run the following substeps:
  1. [Fire a simple event<sup>p846</sup>](#) named [invalid<sup>p1144</sup>](#) that is cancelable at *field*.
  2. If the event was not canceled, then add *field* to *unhandled invalid controls*.
7. Return a *negative* result with the list of elements in the *unhandled invalid controls* list.

If a user agent is to **interactively validate the constraints** of [form<sup>p447</sup>](#) element *form*, then the user agent must run the following steps:

1. [Statically validate the constraints<sup>p554</sup>](#) of *form*, and let *unhandled invalid controls* be the list of elements returned if the result was *negative*.
2. If the result was *positive*, then return that result and abort these steps.
3. Report the problems with the constraints of at least one of the elements given in *unhandled invalid controls* to the user. User agents may focus one of those elements in the process, by running the [focusing steps<sup>p730</sup>](#) for that element, and may change the scrolling position of the document, or perform some other action that brings the element to the user's attention. User agents may report more than one constraint violation. User agents may coalesce related constraint violation reports if appropriate (e.g. if multiple radio buttons in a [group<sup>p475</sup>](#) are marked as required, only one error need be reported). If one of the controls is not [being rendered<sup>p1058</sup>](#) (e.g. it has the [hidden<sup>p723</sup>](#) attribute set) then user agents may report a script error.
4. Return a *negative* result.

#### 4.10.21.3 The constraint validation API

##### Note

**`element.willValidatep555`**

Returns true if the element will be validated when the form is submitted; false otherwise.

**`element.setCustomValidityp555(message)`**

Sets a custom error, so that the element would fail to validate. The given message is the message to be shown to the user when reporting the problem to the user.

If the argument is the empty string, clears the custom error.

**`element.validityp556.valueMissingp556`**

Returns true if the element has no value but is a required field; false otherwise.

**`element.validityp556.typeMismatchp556`**

Returns true if the element's value is not in the correct syntax; false otherwise.

`element.validity.patternMismatch`

Returns true if the element's value doesn't match the provided pattern; false otherwise.

`element.validity.tooLong`

Returns true if the element's value is longer than the provided maximum length; false otherwise.

`element.validity.tooShort`

Returns true if the element's value, if it is not the empty string, is shorter than the provided minimum length; false otherwise.

`element.validity.rangeUnderflow`

Returns true if the element's value is lower than the provided minimum; false otherwise.

`element.validity.rangeOverflow`

Returns true if the element's value is higher than the provided maximum; false otherwise.

`element.validity.stepMismatch`

Returns true if the element's value doesn't fit the rules given by the `step` attribute; false otherwise.

`element.validity.badInput`

Returns true if the user has provided input in the user interface that the user agent is unable to convert to a value; false otherwise.

`element.validity.customError`

Returns true if the element has a custom error; false otherwise.

`element.validity.valid`

Returns true if the element's value has no validity problems; false otherwise.

`valid = element.checkValidity()`

Returns true if the element's value has no validity problems; false otherwise. Fires an `invalid` event at the element in the latter case.

`valid = element.reportValidity()`

Returns true if the element's value has no validity problems; otherwise, returns false, fires an `invalid` event at the element, and (if the event isn't canceled) reports the problem to the user.

`element.validationMessage`

Returns the error message that would be shown to the user if the element was to be checked for validity.

The `willValidate` attribute must return true if an element is a [candidate for constraint validation](#), and false otherwise (i.e. false if any conditions are [barring it from constraint validation](#)).

The `setCustomValidity(message)`, when invoked, must set the [custom validity error message](#) to the value of the given `message` argument.

### Example

In the following example, a script checks the value of a form control each time it is edited, and whenever it is not a valid value, uses the `setCustomValidity()` method to set an appropriate message.

```
<label>Feeling: <input name=f type="text" oninput="check(this)"></label>
<script>
function check(input) {
 if (input.value == "good" ||
 input.value == "fine" ||
 input.value == "tired") {
 input.setCustomValidity("'" + input.value + "' is not a feeling.");
 } else {
 // input is fine -- reset the error message
 input.setCustomValidity('');
 }
}
```

```

 }
}

</script>

```

The **validity** attribute must return a [ValidityState<sup>p556</sup>](#) object that represents the [validity states<sup>p553</sup>](#) of the element. This object is [live<sup>p43</sup>](#).

#### IDL

```

interface ValidityState {
 readonly attribute boolean valueMissing;
 readonly attribute boolean typeMismatch;
 readonly attribute boolean patternMismatch;
 readonly attribute boolean tooLong;
 readonly attribute boolean tooShort;
 readonly attribute boolean rangeUnderflow;
 readonly attribute boolean rangeOverflow;
 readonly attribute boolean stepMismatch;
 readonly attribute boolean badInput;
 readonly attribute boolean customError;
 readonly attribute boolean valid;
};

```

A [ValidityState<sup>p556</sup>](#) object has the following attributes. On getting, they must return true if the corresponding condition given in the following list is true, and false otherwise.

#### **valueMissing**

The control is [suffering from being missing<sup>p553</sup>](#).

#### **typeMismatch**

The control is [suffering from a type mismatch<sup>p553</sup>](#).

#### **patternMismatch**

The control is [suffering from a pattern mismatch<sup>p553</sup>](#).

#### **tooLong**

The control is [suffering from being too long<sup>p553</sup>](#).

#### **tooShort**

The control is [suffering from being too short<sup>p553</sup>](#).

#### **rangeUnderflow**

The control is [suffering from an underflow<sup>p553</sup>](#).

#### **rangeOverflow**

The control is [suffering from an overflow<sup>p553</sup>](#).

#### **stepMismatch**

The control is [suffering from a step mismatch<sup>p553</sup>](#).

#### **badInput**

The control is [suffering from bad input<sup>p553</sup>](#).

#### **customError**

The control is [suffering from a custom error<sup>p553</sup>](#).

#### **valid**

None of the other conditions are true.

When the **checkValidity()** method is invoked, if the element is a [candidate for constraint validation<sup>p553</sup>](#) and does not [satisfy its constraints<sup>p553</sup>](#), the user agent must [fire a simple event<sup>p846</sup>](#) named [invalid<sup>p1144</sup>](#) that is cancelable (but in this case has no default action) at the element and return false. Otherwise, it must only return true without doing anything else.

When the `reportValidity()` method is invoked, if the element is a [candidate for constraint validation](#)<sup>p553</sup> and does not [satisfy its constraints](#)<sup>p553</sup>, the user agent must: [fire a simple event](#)<sup>p846</sup> named `invalid`<sup>p114</sup> that is cancelable at the element, and if that event is not canceled, report the problems with the constraints of that element to the user; then, return false. Otherwise, it must only return true without doing anything else. When reporting the problem with the constraints to the user, the user agent may run the [focusing steps](#)<sup>p730</sup> for that element, and may change the scrolling position of the document, or perform some other action that brings the element to the user's attention. User agents may report more than one constraint violation, if the element suffers from multiple problems at once. If the element is not [being rendered](#)<sup>p1058</sup>, then the user agent may, instead of notifying the user, report a script error.

The `validationMessage` attribute must return the empty string if the element is not a [candidate for constraint validation](#)<sup>p553</sup> or if it is one but it [satisfies its constraints](#)<sup>p553</sup>; otherwise, it must return a suitably localised message that the user agent would show the user if this were the only form control with a validity constraint problem. If the user agent would not actually show a textual message in such a situation (e.g. it would show a graphical cue instead), then the attribute must return a suitably localised message that expresses (one or more of) the validity constraint(s) that the control does not satisfy. If the element is a [candidate for constraint validation](#)<sup>p553</sup> and is [suffering from a custom error](#)<sup>p553</sup>, then the [custom validity error message](#)<sup>p553</sup> should be present in the return value.

#### 4.10.21.4 Security

Servers should not rely on client-side validation. Client-side validation can be intentionally bypassed by hostile users, and unintentionally bypassed by users of older user agents or automated tools that do not implement these features. The constraint validation features are only intended to improve the user experience, not to provide any kind of security mechanism.

### 4.10.22 Form submission

#### 4.10.22.1 Introduction

*This section is non-normative.*

When a form is submitted, the data in the form is converted into the structure specified by the `enctype`<sup>p532</sup>, and then sent to the destination specified by the `action`<sup>p531</sup> using the given `method`<sup>p531</sup>.

For example, take the following form:

```
<form action="/find.cgi" method=get>
 <input type=text name=t>
 <input type=search name=q>
 <input type=submit>
</form>
```

If the user types in "cats" in the first field and "fur" in the second, and then hits the submit button, then the user agent will load `/find.cgi?t=cats&q=fur`.

On the other hand, consider this form:

```
<form action="/find.cgi" method=post enctype="multipart/form-data">
 <input type=text name=t>
 <input type=search name=q>
 <input type=submit>
</form>
```

Given the same user input, the result on submission is quite different: the user agent instead does an HTTP POST to the given URL, with as the entity body something like the following text:

```
-----kYFrd4jNJEgCervE
Content-Disposition: form-data; name="t"

cats
-----kYFrd4jNJEgCervE
Content-Disposition: form-data; name="q"
```

fur  
-----kYFrd4jNJEGCerve--

#### 4.10.22.2 Implicit submission

A [form](#) element's **default button** is the first [submit button](#) in [tree order](#) whose [form owner](#) is that [form](#) element.

If the user agent supports letting the user submit a form implicitly (for example, on some platforms hitting the "enter" key while a text field is [focused](#) implicitly submits the form), then doing so for a form whose [default button](#) has a defined [activation behaviour](#) must cause the user agent to [run synthetic click activation steps](#) on that [default button](#).

**Note** Consequently, if the [default button](#) is [disabled](#), the form is not submitted when such an implicit submission mechanism is used. (A button has no [activation behaviour](#) when disabled.)

**Note** There are pages on the Web that are only usable if there is a way to implicitly submit forms, so user agents are strongly encouraged to support this.

If the form has no [submit button](#), then the implicit submission mechanism must do nothing if the form has more than one [field that blocks implicit submission](#), and must [submit](#) the [form](#) element from the [form](#) element itself otherwise.

For the purpose of the previous paragraph, an element is a [field that blocks implicit submission](#) of a [form](#) element if it is an [input](#) element whose [form owner](#) is that [form](#) element and whose [type](#) attribute is in one of the following states: [Text](#), [Search](#), [URL](#), [Telephone](#), [E-mail](#), [Password](#), [Date and Time](#), [Date](#), [Month](#), [Week](#), [Time](#), [Local Date and Time](#), [Number](#)

#### 4.10.22.3 Form submission algorithm

Spec bugs: [12230](#)

When a [form](#) element *form* is **submitted** from an element *submitter* (typically a button), optionally with a [submitted from](#) [submit \(\)](#) method flag set, the user agent must run the following steps:

1. Let *form document* be the *form*'s [node document](#).
2. If *form document* has no associated [browsing context](#) or its [active sandboxing flag set](#) has its [sandboxed forms browsing context flag](#) set, then abort these steps without doing anything.
3. Let *form browsing context* be the [browsing context](#) of *form document*.
4. If the [submitted from](#) [submit \(\)](#) method flag is not set, and the *submitter* element's [no-validate state](#) is false, then [interactively validate the constraints](#) of *form* and examine the result: if the result is negative (the constraint validation concluded that there were invalid fields and probably informed the user of this) then [fire a simple event](#) named [invalid](#) at the *form* element and then abort these steps.
5. If the [submitted from](#) [submit \(\)](#) method flag is not set, then [fire a simple event](#) that bubbles and is cancelable named [submit](#), at *form*. If the event's default action is prevented (i.e. if the event is canceled) then abort these steps. Otherwise, continue (effectively the default action is to perform the submission).
6. Let *form data set* be the result of [constructing the form data set](#) for *form* in the context of *submitter*.
7. Let *action* be the *submitter* element's [action](#).
8. If *action* is the empty string, let *action* be [the document's address](#) of the *form document*.
9. [Resolve](#) the [URL](#) *action*, relative to the *submitter* element. If this fails, abort these steps.
10. Let *action* be the resulting [absolute URL](#).
11. Let *action components* be the resulting [parsed URL](#).
12. Let *scheme* be the [scheme](#) of the resulting [parsed URL](#).
13. Let *enctype* be the *submitter* element's [enctype](#).

14. Let *method* be the *submitter* element's [method](#)<sup>p531</sup>.
15. Let *target* be the *submitter* element's [target](#)<sup>p532</sup>.
16. If the user indicated a specific [browsing context](#)<sup>p762</sup> to use when submitting the form, then let *target browsing context* be that [browsing context](#)<sup>b762</sup>. Otherwise, apply [the rules for choosing a browsing context given a browsing context name](#)<sup>p767</sup> using *target* as the name and *form browsing context* as the context in which the algorithm is executed, and let *target browsing context* be the resulting [browsing context](#)<sup>b762</sup>.
17. If *target browsing context* was created in the previous step, or, alternatively, if the *form document* has not yet [completely loaded](#)<sup>p1033</sup> and the *submitted from* [submit \(\)](#)<sup>p450</sup> method flag is set, then let *replace* be true. Otherwise, let it be false.
18. If the value of *method* is [dialog](#)<sup>p531</sup> then jump to the [submit dialog](#)<sup>p561</sup> steps.

Otherwise, select the appropriate row in the table below based on the value of *scheme* as given by the first cell of each row. Then, select the appropriate cell on that row based on the value of *method* as given in the first cell of each column. Then, jump to the steps named in that cell and defined below the table.

	<a href="#">GET</a> <sup>p531</sup>	<a href="#">POST</a> <sup>p531</sup>
http	<a href="#">Mutate action URL</a> <sup>p559</sup>	<a href="#">Submit as entity body</a> <sup>b559</sup>
https	<a href="#">Mutate action URL</a> <sup>p559</sup>	<a href="#">Submit as entity body</a> <sup>b559</sup>
ftp	<a href="#">Get action URL</a> <sup>p560</sup>	<a href="#">Get action URL</a> <sup>p560</sup>
javascript	<a href="#">Get action URL</a> <sup>p560</sup>	<a href="#">Get action URL</a> <sup>p560</sup>
data	<a href="#">Get action URL</a> <sup>p560</sup>	<a href="#">Post to data</a> <sup>p560</sup>
mailto	<a href="#">Mail with headers</a> <sup>p560</sup>	<a href="#">Mail as body</a> <sup>b560</sup>

If *scheme* is not one of those listed in this table, then the behaviour is not defined by this specification. User agents should, in the absence of another specification defining this, act in a manner analogous to that defined in this specification for similar schemes.

Each [form](#)<sup>p447</sup> element has a **planned navigation**, which is either null or a [task](#)<sup>p834</sup>; when the [form](#)<sup>p447</sup> is first created, its [planned navigation](#)<sup>b559</sup> must be set to null. In the behaviours described below, when the user agent is required to **plan to navigate** to a particular resource *destination*, it must run the following steps:

1. If the [form](#)<sup>p447</sup> has a non-null [planned navigation](#)<sup>p559</sup>, remove it from its [task queue](#)<sup>p834</sup>.
2. Let the [form](#)<sup>p447</sup>'s [planned navigation](#)<sup>b559</sup> be a new [task](#)<sup>p834</sup> that consists of running the following steps:
  1. Let the [form](#)<sup>p447</sup>'s [planned navigation](#)<sup>p559</sup> be null.
  2. [Navigate](#)<sup>p791</sup> *target browsing context* to the particular resource *destination*. If *replace* is true, then *target browsing context* must be navigated with [replacement enabled](#)<sup>p802</sup>.

For the purposes of this task, *target browsing context* and *replace* are the variables that were set up when the overall form submission algorithm was run, with their values as they stood when this [planned navigation](#)<sup>p559</sup> was [queued](#)<sup>p835</sup>.

3. [Queue the task](#)<sup>p835</sup> that is the [form](#)<sup>p447</sup>'s new [planned navigation](#)<sup>p559</sup>.

The [task source](#)<sup>p835</sup> for this task is the [DOM manipulation task source](#)<sup>p838</sup>.

The behaviours are as follows:

#### **Mutate action URL**

Let *query* be the result of encoding the *form data set* using the [application/x-www-form-urlencoded encoding algorithm](#)<sup>p563</sup>, interpreted as a US-ASCII string.

Set *parsed action*'s [query](#)<sup>p48</sup> component to *query*.

Let *destination* be a new [URL](#)<sup>p48</sup> formed by applying the [URL serialiser](#)<sup>p48</sup> algorithm to *parsed action*.

[Plan to navigate](#)<sup>p559</sup> to *destination*.

#### **Submit as entity body**

Let *entity body* be the result of encoding the *form data set* using the [appropriate form encoding algorithm](#)<sup>p561</sup>.

Let *MIME type* be determined as follows:

If *enctype* is [application/x-www-form-urlencoded<sup>p532</sup>](#)

Let *MIME type* be "[application/x-www-form-urlencoded<sup>p1119</sup>](#)".

If *enctype* is [multipart/form-data<sup>p532</sup>](#)

Let *MIME type* be the concatenation of the string "multipart/form-data;", a U+0020 SPACE character, the string "boundary=", and the [multipart/form-data boundary string<sup>p566</sup>](#) generated by the [multipart/form-data encoding algorithm<sup>p565</sup>](#).

If *enctype* is [text/plain<sup>p532</sup>](#)

Let *MIME type* be "text/plain".

Otherwise, [plan to navigate<sup>p559</sup>](#) to *action* using the HTTP method given by *method* and with *entity body* as the entity body, of type *MIME type*.

#### Get *action URL*

[Plan to navigate<sup>p559</sup>](#) to *action*.

**Note** The form data set is discarded.

#### Post to data:

Let *data* be the result of encoding the *form data set* using the [appropriate form encoding algorithm<sup>p561</sup>](#).

If *action* contains the string "%%%%" (four U+0025 PERCENT SIGN characters), then [percent encode<sup>p48</sup>](#) all bytes in *data* that, if interpreted as US-ASCII, are not characters in the URL [default encode set<sup>p48</sup>](#), and then, treating the result as a US-ASCII string, [UTF-8 percent encode<sup>p48</sup>](#) all the U+0025 PERCENT SIGN characters in the resulting string and replace the first occurrence of "%%%%" in *action* with the resulting doubly-escaped string. [\[URL\]<sup>p1153</sup>](#)

Otherwise, if *action* contains the string "%%" (two U+0025 PERCENT SIGN characters in a row, but not four), then [UTF-8 percent encode<sup>p48</sup>](#) all characters in *data* that, if interpreted as US-ASCII, are not characters in the URL [default encode set<sup>p48</sup>](#), and then, treating the result as a US-ASCII string, replace the first occurrence of "%%" in *action* with the resulting escaped string. [\[URL\]<sup>p1153</sup>](#)

[Plan to navigate<sup>p559</sup>](#) to the potentially modified *action* (which will be a [data: URL](#)).

#### Mail with headers

Let *headers* be the resulting encoding the *form data set* using the [application/x-www-form-urlencoded encoding algorithm<sup>p563</sup>](#), interpreted as a US-ASCII string.

Replace occurrences of U+002B PLUS SIGN characters (+) in *headers* with the string "%20".

Let *destination* consist of all the characters from the first character in *action* to the character immediately before the first U+003F QUESTION MARK character (?), if any, or the end of the string if there are none.

Append a single U+003F QUESTION MARK character (?) to *destination*.

Append *headers* to *destination*.

[Plan to navigate<sup>p559</sup>](#) to *destination*.

#### Mail as body

Let *body* be the resulting of encoding the *form data set* using the [appropriate form encoding algorithm<sup>p561</sup>](#) and then [percent encoding<sup>p48</sup>](#) all the bytes in the resulting byte string that, when interpreted as US-ASCII, are not characters in the URL [default encode set<sup>p48</sup>](#). [\[URL\]<sup>p1153</sup>](#)

Let *destination* have the same value as *action*.

If *destination* does not contain a U+003F QUESTION MARK character (?), append a single U+003F QUESTION MARK character (?) to *destination*. Otherwise, append a single U+0026 AMPERSAND character (&).

Append the string "body=" to *destination*.

Append *body*, interpreted as a US-ASCII string, to *destination*.

[Plan to navigate](#)<sup>p559</sup> to destination.

### Submit dialog

Let *subject* be the nearest ancestor [dialog](#)<sup>p586</sup> element of *form*, if any.

If there isn't one, or if it does not have an [open](#)<sup>p586</sup> attribute, do nothing. Otherwise, proceed as follows:

If *submitter* is an [input](#)<sup>p452</sup> element whose [type](#)<sup>p454</sup> attribute is in the [Image Button](#)<sup>p479</sup> state, then let *result* be the string formed by concatenating the [selected coordinate](#)<sup>p480</sup>'s x-component, expressed as a base-ten number using [ASCII digits](#)<sup>p58</sup>, a U+002C COMMA character (,), and the [selected coordinate](#)<sup>p480</sup>'s y-component, expressed in the same way as the x-component.

Otherwise, if *submitter* has a [value](#)<sup>p527</sup>, then let *result* be that [value](#)<sup>p527</sup>.

Otherwise, there is no *result*.

Then, [close the dialog](#)<sup>p588</sup> *subject*. If there is a *result*, let that be the return value.

The **appropriate form encoding algorithm** is determined as follows:

If *enctype* is [application/x-www-form-urlencoded](#)<sup>p532</sup>

Use the [application/x-www-form-urlencoded encoding algorithm](#)<sup>p563</sup>.

If *enctype* is [multipart/form-data](#)<sup>p532</sup>

Use the [multipart/form-data encoding algorithm](#)<sup>p565</sup>.

If *enctype* is [text/plain](#)<sup>p532</sup>

Use the [text/plain encoding algorithm](#)<sup>p566</sup>.

#### 4.10.22.4 Constructing the form data set

The algorithm to **construct the form data set** for a form *form* optionally in the context of a submitter *submitter* is as follows. If not specified otherwise, *submitter* is null.

1. Let *controls* be a list of all the [submittable elements](#)<sup>p447</sup> whose [form owner](#)<sup>p527</sup> is *form*, in [tree order](#)<sup>p42</sup>.
2. Let the *form data set* be a list of name-value-type tuples, initially empty.
3. *Loop*: For each element *field* in *controls*, in [tree order](#)<sup>p42</sup>, run the following substeps:
  1. If any of the following conditions are met, then skip these substeps for this element:
    - The *field* element has a [datalist](#)<sup>p503</sup> element ancestor.
    - The *field* element is [disabled](#)<sup>p530</sup>.
    - The *field* element is a [button](#)<sup>p447</sup> but it is not *submitter*.
    - The *field* element is an [input](#)<sup>p452</sup> element whose [type](#)<sup>p454</sup> attribute is in the [Checkbox](#)<sup>p475</sup> state and whose [checkedness](#)<sup>p527</sup> is false.
    - The *field* element is an [input](#)<sup>p452</sup> element whose [type](#)<sup>p454</sup> attribute is in the [Radio Button](#)<sup>p475</sup> state and whose [checkedness](#)<sup>p527</sup> is false.
    - The *field* element is not an [input](#)<sup>p452</sup> element whose [type](#)<sup>p454</sup> attribute is in the [Image Button](#)<sup>p479</sup> state, and either the *field* element does not have a [name](#)<sup>p529</sup> attribute specified, or its [name](#)<sup>p529</sup> attribute's value is the empty string.
    - The *field* element is an [object](#)<sup>p310</sup> element that is not using a [plugin](#)<sup>p43</sup>.
  - Otherwise, process *field* as follows:

2. Let *type* be the value of the [type](#) IDL attribute of *field*.

3. If the *field* element is an *input*<sup>p452</sup> element whose *type*<sup>p454</sup> attribute is in the *Image Button*<sup>p479</sup> state, then run these further nested substeps:

1. If the *field* element has a *name*<sup>p529</sup> attribute specified and its value is not the empty string, let *name* be that value followed by a single U+002E FULL STOP character (.). Otherwise, let *name* be the empty string.
  2. Let *namex* be the string consisting of the concatenation of *name* and a single U+0078 LATIN SMALL LETTER X character (x).
  3. Let *namey* be the string consisting of the concatenation of *name* and a single U+0079 LATIN SMALL LETTER Y character (y).
  4. The *field* element is *submitter*, and before this algorithm was invoked the user indicated a coordinate<sup>p480</sup>. Let *x* be the *x*-component of the coordinate selected by the user, and let *y* be the *y*-component of the coordinate selected by the user.
  5. Append an entry to the *form data set* with the name *namex*, the value *x*, and the type *type*.
  6. Append an entry to the *form data set* with the name *namey* and the value *y*, and the type *type*.
  7. Skip the remaining substeps for this element: if there are any more elements in *controls*, return to the top of the *loop* step, otherwise, jump to the *end* step below.
4. Let *name* be the value of the *field* element's *name*<sup>b529</sup> attribute.
  5. If the *field* element is a *select*<sup>p498</sup> element, then for each *option*<sup>p505</sup> element in the *select*<sup>p498</sup> element's *list of options*<sup>p499</sup> whose *selectedness*<sup>p507</sup> is true and that is not *disabled*<sup>p506</sup>, append an entry to the *form data set* with the *name* as the name, the *value*<sup>p506</sup> of the *option*<sup>p505</sup> element as the value, and *type* as the type.
  6. Otherwise, if the *field* element is an *input*<sup>p452</sup> element whose *type*<sup>p454</sup> attribute is in the *Checkbox*<sup>p475</sup> state or the *Radio Button*<sup>p475</sup> state, then run these further nested substeps:
    1. If the *field* element has a *value*<sup>p457</sup> attribute specified, then let *value* be the value of that attribute; otherwise, let *value* be the string "on".
    2. Append an entry to the *form data set* with *name* as the name, *value* as the value, and *type* as the type.
  7. Otherwise, if the *field* element is an *input*<sup>p452</sup> element whose *type*<sup>p454</sup> attribute is in the *File Upload*<sup>p476</sup> state, then for each file *selected*<sup>p476</sup> in the *input*<sup>p452</sup> element, append an entry to the *form data set* with the *name* as the name, the file (consisting of the name, the type, and the body) as the value, and *type* as the type. If there are no *selected files*<sup>p476</sup>, then append an entry to the *form data set* with the *name* as the name, the empty string as the value, and *application/octet-stream* as the type.
  8. Otherwise, if the *field* element is an *object*<sup>p310</sup> element: try to obtain a form submission value from the *plugin*<sup>p43</sup>, and if that is successful, append an entry to the *form data set* with *name* as the name, the returned form submission value as the value, and the string "*object*" as the type.
  9. Otherwise, append an entry to the *form data set* with *name* as the name, the *value*<sup>p527</sup> of the *field* element as the value, and *type* as the type.
  10. If the element has a *dirname*<sup>p529</sup> attribute, and that attribute's value is not the empty string, then run these substeps:
    1. Let *dirname* be the value of the element's *dirname*<sup>p529</sup> attribute.
    2. Let *dir* be the string "ltr" if *the directionality*<sup>p125</sup> of the element is "ltr"<sup>p125</sup>, and "rtl" otherwise (i.e. when *the directionality*<sup>p125</sup> of the element is "rtl"<sup>p125</sup>).
    3. Append an entry to the *form data set* with *dirname* as the name, *dir* as the value, and the string "direction" as the type.

**Note** An element can only have a *dirname*<sup>p529</sup> attribute if it is a *textarea*<sup>p508</sup> element or an *input*<sup>p452</sup> element whose *type*<sup>p454</sup> attribute is in either the *Text*<sup>p458</sup> state or the *Search*<sup>p458</sup> state.

4. *End*: For the name of each entry in the *form data set*, and for the value of each entry in the *form data set* whose type is not "file" or "textarea", replace every occurrence of a U+000D CARRIAGE RETURN (CR) character not followed by a U+000A LINE FEED (LF)

character, and every occurrence of a U+000A LINE FEED (LF) character not preceded by a U+000D CARRIAGE RETURN (CR) character, by a two-character string consisting of a U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF) character pair.

**Note** In the case of the `value`<sup>p527</sup> of `textarea`<sup>p508</sup> elements, this newline normalization is already performed during the conversion of the control's `raw value`<sup>p509</sup> into the control's `value`<sup>p527</sup> (which also performs any necessary line wrapping). In the case of `input`<sup>p452</sup> elements `type`<sup>p454</sup> attributes in the `File Upload`<sup>p476</sup> state, the value is not normalized.

5. Return the `form data set`.

#### 4.10.22.5 Selecting a form submission encoding

If the user agent is to pick an encoding for a form, optionally with an `allow non-ASCII-compatible encodings` flag set, it must run the following substeps:

1. Let `input` be the value of the `form`<sup>p447</sup> element's `accept-charset`<sup>p448</sup> attribute.
2. Let `candidate encoding labels` be the result of `splitting input on spaces`<sup>p80</sup>.
3. Let `candidate encodings` be an empty list of `character encodings`<sup>p44</sup>.
4. For each token in `candidate encoding labels` in turn (in the order in which they were found in `input`), `get an encoding` for the token and, if this does not result in failure, append the `encoding`<sup>p44</sup> to `candidate encodings`.
5. If the `allow non-ASCII-compatible encodings` flag is not set, remove any encodings that are not `ASCII-compatible character encodings`<sup>p44</sup> from `candidate encodings`.
6. If `candidate encodings` is empty, return UTF-8 and abort these steps.
7. Each character encoding in `candidate encodings` can represent a finite number of characters. (For example, UTF-8 can represent all 1.1 million or so Unicode code points, while Windows-1252 can only represent 256.)

For each encoding in `candidate encodings`, determine how many of the characters in the names and values of the entries in the `form data set` the encoding can represent (without ignoring duplicates). Let `max` be the highest such count. (For UTF-8, `max` would equal the number of characters in the names and values of the entries in the `form data set`.)

Return the first encoding in `candidate encodings` that can encode `max` characters in the names and values of the entries in the `form data set`.

#### 4.10.22.6 URL-encoded form data

**Note** This form data set encoding is in many ways an aberrant monstrosity, the result of many years of implementation accidents and compromises leading to a set of requirements necessary for interoperability, but in no way representing good design practices. In particular, readers are cautioned to pay close attention to the twisted details involving repeated (and in some cases nested) conversions between character encodings and byte sequences.

The `application/x-www-form-urlencoded` encoding algorithm is as follows:

Spec bugs: [17725](#)

1. Let `result` be the empty string.
2. If the `form`<sup>p447</sup> element has an `accept-charset`<sup>p448</sup> attribute, let the selected character encoding be the result of `picking an encoding for the form`<sup>p563</sup>.  
Otherwise, if the `form`<sup>p447</sup> element has no `accept-charset`<sup>p448</sup> attribute, but the `document's character encoding`<sup>p51</sup> is an `ASCII-compatible character encoding`<sup>p44</sup>, then that is the selected character encoding.  
Otherwise, let the selected character encoding be UTF-8.
3. Let `charset` be the `name`<sup>p44</sup> of the selected `character encoding`<sup>p44</sup>.
4. For each entry in the `form data set`, perform these substeps:
  1. If the entry's name is "`charset`" and its type is "hidden", replace its value with `charset`.

2. If the entry's type is "`file`", replace its value with the file's name only.
  3. For each character in the entry's name and value that cannot be expressed using the selected character encoding, replace the character by a string consisting of a U+0026 AMPERSAND character (&), a U+0023 NUMBER SIGN character (#), one or more [ASCII digits](#)<sup>p58</sup> representing the Unicode code point of the character in base ten, and finally a U+003B SEMICOLON character (;).
  4. Encode the entry's name and value using the [encoder](#)<sup>p47</sup> for the selected character encoding. The entry's name and value are now byte strings.
  5. For each byte in the entry's name and value, apply the appropriate subsubsteps from the following list:
    - ↪ **If the byte is 0x20 (U+0020 SPACE if interpreted as ASCII)**  
Replace the byte with a single 0x2B byte (U+002B PLUS SIGN character (+) if interpreted as ASCII).
    - ↪ **If the byte is in the range 0x2A, 0x2D, 0x2E, 0x30 to 0x39, 0x41 to 0x5A, 0x5F, 0x61 to 0x7A**  
Leave the byte as is.
    - ↪ **Otherwise**
      1. Let *s* be a string consisting of a U+0025 PERCENT SIGN character (%) followed by [uppercase ASCII hex digits](#)<sup>p59</sup> representing the hexadecimal value of the byte in question (zero-padded if necessary).
      2. Encode the string *s* as US-ASCII, so that it is now a byte string.
      3. Replace the byte in question in the name or value being processed by the bytes in *s*, preserving their relative order.
  6. Interpret the entry's name and value as Unicode strings encoded in US-ASCII. (All of the bytes in the string will be in the range 0x00 to 0x7F; the high bit will be zero throughout.) The entry's name and value are now Unicode strings again.
  7. If the entry's name is "`isindex`"<sup>p529</sup>, its type is "`text`", and this is the first entry in the *form data set*, then append the value to *result* and skip the rest of the substeps for this entry, moving on to the next entry, if any, or the next step in the overall algorithm otherwise.
  8. If this is not the first entry, append a single U+0026 AMPERSAND character (&) to *result*.
  9. Append the entry's name to *result*.
  10. Append a single U+003D EQUALS SIGN character (=) to *result*.
  11. Append the entry's value to *result*.
5. Encode *result* as US-ASCII and return the resulting byte stream.

To decode `application/x-www-form-urlencoded` payloads, the following algorithm should be used. This algorithm uses as inputs the payload itself, *payload*, consisting of a Unicode string using only characters in the range U+0000 to U+007F; a default character encoding *encoding*; and optionally an *isindex* flag indicating that the payload is to be processed as if it had been generated for a form containing an `isindex`<sup>p529</sup> control. The output of this algorithm is a sorted list of name-value pairs. If the *isindex* flag is set and the first control really was an `isindex`<sup>p529</sup> control, then the first name-value pair will have as its name the empty string.

Which default character encoding to use can only be determined on a case-by-case basis, but generally the best character encoding to use as a default is the one that was used to encode the page on which the form used to create the payload was itself found. In the absence of a better default, UTF-8 is suggested.

The *isindex* flag is for legacy use only. Forms in conforming HTML documents will not generate payloads that need to be decoded with this flag set.

1. Let *strings* be the result of [strictly splitting the string](#)<sup>p59</sup> *payload* on U+0026 AMPERSAND characters (&).
2. If the *isindex* flag is set and the first string in *strings* does not contain a U+003D EQUALS SIGN character (=), insert a U+003D EQUALS SIGN character (=) at the start of the first string in *strings*.
3. Let *pairs* be an empty list of name-value pairs.
4. For each string *string* in *strings*, run these substeps:

1. If *string* contains a U+003D EQUALS SIGN character (=), then let *name* be the substring of *string* from the start of *string* up to but excluding its first U+003D EQUALS SIGN character (=), and let *value* be the substring from the first character, if any, after the first U+003D EQUALS SIGN character (=) up to the end of *string*. If the first U+003D EQUALS SIGN character (=) is the first character, then *name* will be the empty string. If it is the last character, then *value* will be the empty string.

Otherwise, *string* contains no U+003D EQUALS SIGN characters (=). Let *name* have the value of *string* and let *value* be the empty string.

2. Replace any U+002B PLUS SIGN characters (+) in *name* and *value* with U+0020 SPACE characters.
3. Replace any escape in *name* and *value* with the character represented by the escape. This replacement must not be recursive.

An escape is a U+0025 PERCENT SIGN character (%) followed by two [ASCII hex digits](#)<sup>p59</sup>.

The character represented by an escape is the Unicode character whose code point is equal to the value of the two characters after the U+0025 PERCENT SIGN character (%), interpreted as a hexadecimal number (in the range 0..255).

**Example** So for instance the string "A%2BC" would become "A+C". Similarly, the string "100%25AA%21" becomes the string "100%AA!".

4. Convert the *name* and *value* strings to their byte representation in ISO-8859-1 (i.e. convert the Unicode string to a byte string, mapping code points to byte values directly).
5. Add a pair consisting of *name* and *value* to *pairs*.
5. If any of the name-value pairs in *pairs* have a name component consisting of the string "`_charset_`" encoded in US-ASCII, and the value component of the first such pair, when decoded as US-ASCII, is the name of a supported character encoding, then let *encoding* be that character encoding (replacing the default passed to the algorithm).
6. Convert the name and value components of each name-value pair in *pairs* to Unicode by interpreting the bytes according to the encoding *encoding*.
7. Return *pairs*.

**Note** Parameters on the [application/x-www-form-urlencoded](#)<sup>p1119</sup> MIME type are ignored. In particular, this MIME type does not support the `charset` parameter.

#### 4.10.22.7 Multipart form data

Spec bugs: [18135](#), [16909](#)

The **multipart/form-data** encoding algorithm is as follows:

1. Let *result* be the empty string.
2. If the algorithm was invoked with an explicit character encoding, let the selected character encoding be that encoding. (This algorithm is used by other specifications, which provide an explicit character encoding to avoid the dependency on the [form](#)<sup>p447</sup> element described in the next paragraph.)

Otherwise, if the [form](#)<sup>p447</sup> element has an [accept-charset](#)<sup>p448</sup> attribute, let the selected character encoding be the result of [picking an encoding for the form](#)<sup>p563</sup>.

Otherwise, if the [form](#)<sup>p447</sup> element has no [accept-charset](#)<sup>p448</sup> attribute, but the [document's character encoding](#)<sup>p51</sup> is an [ASCII-compatible character encoding](#)<sup>p44</sup>, then that is the selected character encoding.

Otherwise, let the selected character encoding be UTF-8.

3. Let *charset* be the [name](#)<sup>p44</sup> of the selected [character encoding](#)<sup>p44</sup>.
4. For each entry in the *form data set*, perform these substeps:
  1. If the entry's name is "`_charset_`" and its type is "hidden", replace its value with *charset*.
  2. For each character in the entry's name and value that cannot be expressed using the selected character encoding, replace the character by a string consisting of a U+0026 AMPERSAND character (&), a U+0023 NUMBER SIGN character (#), one

or more [ASCII digits](#)<sup>p58</sup> representing the Unicode code point of the character in base ten, and finally a U+003B SEMICOLON character (;).

5. Encode the (now mutated) *form data set* using the rules described by RFC 2388, *Returning Values from Forms: multipart/form-data*, and return the resulting byte stream. [\[RFC2388\]](#)<sup>p1152</sup>

Each entry in the *form data set* is a *field*, the name of the entry is the *field name* and the value of the entry is the *field value*.

The order of parts must be the same as the order of fields in the *form data set*. Multiple entries with the same name must be treated as distinct fields.

**Note** *In particular, this means that multiple files submitted as part of a single <input type="file" multiple> element will result in each file having its own field; the "sets of files" feature ("multipart/mixed") of RFC 2388 is not used.*

The parts of the generated [multipart/form-data](#)<sup>p1146</sup> resource that correspond to non-file fields must not have a [Content-Type](#)<sup>p86</sup> header specified. Their names and values must be encoded using the character encoding selected above (field names in particular do not get converted to a 7-bit safe encoding as suggested in RFC 2388).

File names included in the generated [multipart/form-data](#)<sup>p1146</sup> resource (as part of file fields) must use the character encoding selected above, though the precise name may be approximated if necessary (e.g. newlines could be removed from file names, quotes could be changed to "%22", and characters not expressible in the selected character encoding could be replaced by other characters). User agents must not use the RFC 2231 encoding suggested by RFC 2388.

The boundary used by the user agent in generating the return value of this algorithm is the [multipart/form-data boundary string](#). (This value is used to generate the MIME type of the form submission payload generated by this algorithm.)

For details on how to interpret [multipart/form-data](#)<sup>p1146</sup> payloads, see RFC 2388. [\[RFC2388\]](#)<sup>p1152</sup>

#### 4.10.22.8 Plain text form data

The [text/plain](#) encoding algorithm is as follows:

1. Let *result* be the empty string.
2. If the [form](#)<sup>p447</sup> element has an [accept-charset](#)<sup>p448</sup> attribute, let the selected character encoding be the result of [picking an encoding for the form](#)<sup>p563</sup>, with the *allow non-ASCII-compatible encodings* flag unset.  
Otherwise, if the [form](#)<sup>p447</sup> element has no [accept-charset](#)<sup>p448</sup> attribute, then that is the selected character encoding.
3. Let *charset* be the [name](#)<sup>p44</sup> of the selected [character encoding](#)<sup>p44</sup>.
4. If the entry's name is "[charset](#)"<sup>p529</sup> and its type is "[hidden](#)", replace its value with *charset*.
5. If the entry's type is "[file](#)", replace its value with the file's name only.
6. For each entry in the *form data set*, perform these substeps:
  1. Append the entry's name to *result*.
  2. Append a single U+003D EQUALS SIGN character (=) to *result*.
  3. Append the entry's value to *result*.
  4. Append a U+000D CARRIAGE RETURN (CR) U+000A LINE FEED (LF) character pair to *result*.
7. Encode *result* using the [encoder](#)<sup>p47</sup> for the selected character encoding and return the resulting byte stream.

Payloads using the [text/plain](#) format are intended to be human readable. They are not reliably interpretable by computer, as the format is ambiguous (for example, there is no way to distinguish a literal newline in a value from the newline at the end of the value).

## 4.10.23 Resetting a form

When a `form`<sup>p447</sup> element `form` is `reset`, the user agent must `fire a simple event`<sup>p846</sup> named `reset`<sup>p1144</sup>, that bubbles and is cancelable, at `form`, and then, if that event is not canceled, must invoke the `reset algorithm`<sup>p567</sup> of each `resettable element`<sup>p447</sup> whose `form owner`<sup>p527</sup> is `form`.

When the `reset`<sup>p567</sup> algorithm is invoked by the `reset()`<sup>p450</sup> method, the `reset`<sup>p1144</sup> event fired by the `reset`<sup>p567</sup> algorithm must not be `trusted`<sup>p43</sup>.

Each `resettable element`<sup>p447</sup> defines its own `reset algorithm`. Changes made to form controls as part of these algorithms do not count as changes caused by the user (and thus, e.g., do not cause `input`<sup>p1144</sup> events to fire).

## 4.11 Interactive elements

### 4.11.1 The `details` element

Categories<sup>p113</sup>:

- `Flow content`<sup>p115</sup>.
- `Sectioning root`<sup>p176</sup>.
- `Interactive content`<sup>p116</sup>.
- `Palpable content`<sup>p117</sup>.

Contexts in which this element can be used<sup>p113</sup>:

Where `flow content`<sup>p115</sup> is expected.

Content model<sup>p113</sup>:

One `summary`<sup>p571</sup> element followed by `flow content`<sup>p115</sup>.

Tag omission in text/html<sup>p113</sup>:

Neither tag is omissible.

Content attributes<sup>p113</sup>:

`Global attributes`<sup>p120</sup>

`open`<sup>p567</sup> — Whether the details are visible

DOM interface<sup>p113</sup>:

```
IDL interface HTMLDetailsElement : HTMLElement {
 attribute boolean open;
};
```

The `details`<sup>p567</sup> element `represents`<sup>p111</sup> a disclosure widget from which the user can obtain additional information or controls.

**Note** The `details`<sup>p567</sup> element is not appropriate for footnotes. Please see [the section on footnotes](#)<sup>p677</sup> for details on how to mark up footnotes.

The first `summary`<sup>p571</sup> element child of the element, if any, `represents`<sup>p111</sup> the summary or legend of the details. If there is no child `summary`<sup>p571</sup> element, the user agent should provide its own legend (e.g. "Details").

The rest of the element's contents `represents`<sup>p111</sup> the additional information or controls.

The `open` content attribute is a `boolean attribute`<sup>p59</sup>. If present, it indicates that both the summary and the additional information is to be shown to the user. If the attribute is absent, only the summary is to be shown.

When the element is created, if the attribute is absent, the additional information should be hidden; if the attribute is present, that information should be shown. Subsequently, if the attribute is removed, then the information should be hidden; if the attribute is added, the information should be shown.

The user agent should allow the user to request that the additional information be shown or hidden. To honor a request for the details to be shown, the user agent must set the `open`<sup>p567</sup> attribute on the element to the value `open`. To honor a request for the information to be hidden, the user agent must remove the `open`<sup>p567</sup> attribute from the element.

Spec bugs: 25550

Whenever the `open`<sup>p567</sup> attribute is added to or removed from a `details`<sup>p567</sup> element, the user agent must [queue a task](#)<sup>p835</sup> that runs the following steps, which are known as the **details notification task steps**, for this `details`<sup>p567</sup> element:

1. If another `task`<sup>p834</sup> has been [queued](#)<sup>p835</sup> to run the `details notification task steps`<sup>p568</sup> for this `details`<sup>p567</sup> element, then abort these steps.
- Note** *When the `open`<sup>p567</sup> attribute is toggled several times in succession, these steps essentially get coalesced so that only one event is fired.*
2. [Fire a simple event](#)<sup>p846</sup> named `toggle`<sup>p1145</sup> at the `details`<sup>p567</sup> element.

The `task source`<sup>p835</sup> for this task must be the [DOM manipulation task source](#)<sup>p838</sup>.

The `open` IDL attribute must [reflect](#)<sup>p88</sup> the `open`<sup>p567</sup> content attribute.

#### Example

The following example shows the `details`<sup>p567</sup> element being used to hide technical details in a progress report.

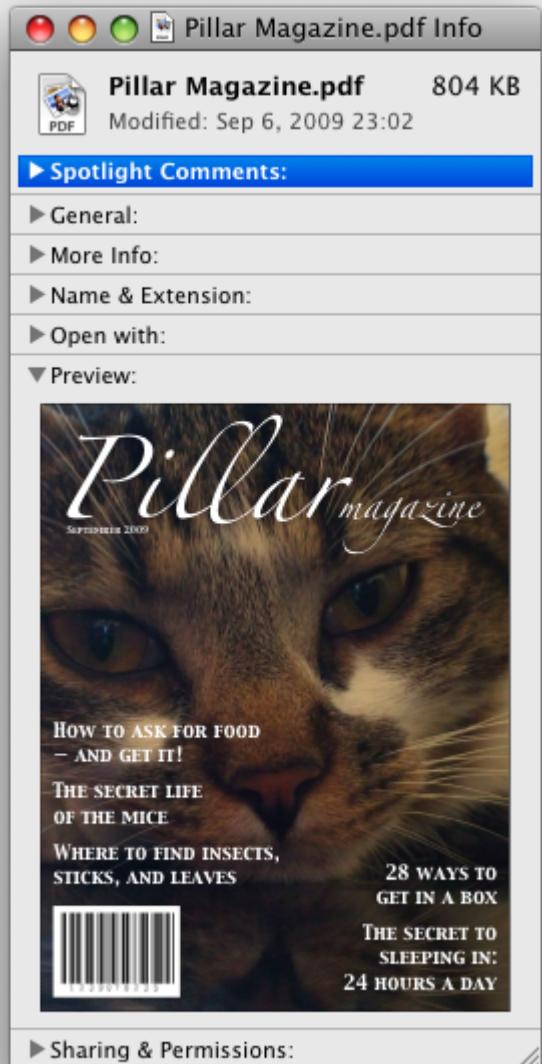

```
<section class="progress window">
 <h1>Copying "Really Achieving Your Childhood Dreams"</h1>
 <details>
 <summary>Copying... <progress max="375505392" value="97543282"></progress> 25%</summary>
 <dl>
 <dt>Transfer rate:</dt> <dd>452KB/s</dd>
 <dt>Local filename:</dt> <dd>/home/rpausch/raycd.m4v</dd>
 <dt>Remote filename:</dt> <dd>/var/www/lectures/raycd.m4v</dd>
 <dt>Duration:</dt> <dd>01:16:27</dd>
 <dt>Colour profile:</dt> <dd>SD (6-1-6)</dd>
 <dt>Dimensions:</dt> <dd>320×240</dd>
 </dl>
 </details>
</section>
```

#### Example

The following shows how a `details`<sup>p567</sup> element can be used to hide some controls by default:

```
<details>
 <summary><label for=fn>Name & Extension:</label></summary>
 <p><input type=text id=fn name=fn value="Pillar Magazine.pdf">
 <p><label><input type=checkbox name=ext checked> Hide extension</label>
</details>
```

One could use this in conjunction with other `details`<sup>p567</sup> in a list to allow the user to collapse a set of fields down to a small set of headings, with the ability to open each one.

In these examples, the summary really just summarises what the controls can change, and not the actual values, which is less than ideal.

### Example

Because the `openp567` attribute is added and removed automatically as the user interacts with the control, it can be used in CSS to style the element differently based on its state. Here, a stylesheet is used to animate the colour of the summary when the element is opened or closed:

```

<style>
 details > summary { transition: color 1s; color: black; }
 details[open] > summary { color: red; }
</style>
<details>
 <summary>Automated Status: Operational</summary>
 <p>Velocity: 12m/s</p>
 <p>Direction: North</p>
</details>

```

## 4.11.2 The `summary` element

### Categories<sup>p113</sup>:

None.

### Contexts in which this element can be used<sup>p113</sup>:

As the first child of a `details`<sup>p567</sup> element.

### Content model<sup>p113</sup>:

Either: `phrasing content`<sup>p116</sup>.

Or: one element of `heading content`<sup>p116</sup>.

### Tag omission in text/html<sup>p113</sup>:

Neither tag is omissible.

### Content attributes<sup>p113</sup>:

`Global attributes`<sup>p120</sup>

### DOM interface<sup>p113</sup>:

Uses `HTMLElement`<sup>p112</sup>.

The `summary`<sup>b571</sup> element `represents`<sup>p111</sup> a summary, caption, or legend for the rest of the contents of the `summary`<sup>b571</sup> element's parent `details`<sup>p567</sup> element, if any.

## 4.11.3 The `menu` element

### Categories<sup>p113</sup>:

`Flow content`<sup>p115</sup>.

If the element's `type`<sup>p572</sup> attribute is in the `toolbar`<sup>p572</sup> state: `Palpable content`<sup>p117</sup>.

### Contexts in which this element can be used<sup>p113</sup>:

Where `flow content`<sup>p115</sup> is expected.

If the element's `type`<sup>p572</sup> attribute is in the `popup menu`<sup>p572</sup> state: as the child of a `menu`<sup>b571</sup> element whose `type`<sup>p572</sup> attr is `popup menu`<sup>p572</sup> state.

### Content model<sup>p113</sup>:

If the element's `type`<sup>p572</sup> attribute is in the `toolbar`<sup>p572</sup> state: either zero or more `li`<sup>p198</sup> and `script-supporting`<sup>p117</sup> elements, or, `flow content`<sup>p115</sup>.

If the element's `type`<sup>p572</sup> attribute is in the `popup menu`<sup>p572</sup> state: in any order, zero or more `menuitem`<sup>p574</sup> elements, zero or more `hr`<sup>p190</sup> elements, zero or more `menu`<sup>p571</sup> elements whose `type`<sup>p572</sup> attributes are in the `popup menu`<sup>p572</sup> state, and zero or more `script-supporting`<sup>p117</sup> elements.

### Tag omission in text/html<sup>p113</sup>:

Neither tag is omissible.

### Content attributes<sup>p113</sup>:

`Global attributes`<sup>p120</sup>

`type`<sup>p572</sup> — Type of menu

`label`<sup>p572</sup> — User-visible label

### DOM interface<sup>p113</sup>:

```
IDL interface HTMLMenuElement : HTMLElement {
 attribute DOMString type;
 attribute DOMString label;
 // also has obsolete members
};
```

The `menu`<sup>b571</sup> element represents a list of commands.

The `type` attribute is an [enumerated attribute<sup>p60</sup>](#) indicating the kind of menu being declared. The attribute has two states. The "popup" keyword maps to the **popup menu** state, in which the element is declaring a context menu or the menu for a [menu button<sup>p497</sup>](#). The "toolbar" keyword maps to the **toolbar** state, in which the element is declaring a toolbar. The attribute may also be omitted. The [missing value default<sup>p60</sup>](#) is the **popup menu<sup>p572</sup>** state if the parent element is a [menu<sup>p571</sup>](#) element whose `typep572` attribute is in the **popup menu<sup>p572</sup>** state; otherwise, it is the **toolbar<sup>p572</sup>** state.

If a [menu<sup>p571</sup>](#) element's `typep572` attribute is in the **popup menu<sup>p572</sup>** state, then the element [represents<sup>p111</sup>](#) the commands of a popup menu, and the user can only examine and interact with the commands if that popup menu is activated through some other element, either via the [contextmenu<sup>p577</sup>](#) attribute or the [button<sup>p495</sup>](#) element's [menu<sup>p497</sup>](#) attribute.

If a [menu<sup>p571</sup>](#) element's `typep572` attribute is in the **toolbar<sup>p572</sup>** state, then the element [represents<sup>p111</sup>](#) a toolbar consisting of its contents, in the form of either an unordered list of items (represented by [li<sup>p198</sup>](#) elements), each of which represents a command that the user can perform or activate, or, if the element has no [li<sup>p198</sup>](#) element children, [flow content<sup>p115</sup>](#) describing available commands.

The `label` attribute gives the label of the menu. It is used by user agents to display nested menus in the UI: a context menu containing another menu would use the nested menu's `labelp572` attribute for the submenu's menu label. The `labelp572` attribute must only be specified on [menu<sup>p571</sup>](#) elements whose parent element is a [menu<sup>p571</sup>](#) element whose `typep572` attribute is in the **popup menu<sup>p572</sup>** state.

A [menu<sup>p571</sup>](#) is a **currently relevant menu element** if it is the child of a [currently relevant menu element<sup>b572</sup>](#), or if it is the [designated pop-up menu<sup>p497</sup>](#) of a [button<sup>p495</sup>](#) element that is not [inert<sup>p724</sup>](#), does not have a [hidden<sup>p723</sup>](#) attribute, and is not the descendant of an element with a [hidden<sup>p723</sup>](#) attribute.

A **menu construct** consists of an ordered list of zero or more **menu item constructs**, which can be any of:

- [Commands<sup>p579</sup>](#), which can be marked as **default commands** ([menuitem<sup>p574</sup>](#))
- [Separators](#) ([hr<sup>p190</sup>](#))
- Other [menu constructs<sup>p572</sup>](#), each with an associated **submenu label**, which allows the list to be nested ([menu<sup>p571</sup>](#))

To **build and show a menu** for a particular [menu<sup>p571</sup>](#) element **source** and with a particular element **subject** as a subject, the user agent must run the following steps:

1. Let **pop-up menu** be the [menu construct<sup>p572</sup>](#) created by the [build a menu construct<sup>p572</sup>](#) algorithm when passed the **source** element.
2. Display **pop-up menu** to the user, and let the algorithm that invoked this one continue.

If the user selects a [menu item construct<sup>p572</sup>](#) that corresponds to an element that still represents a [command<sup>p579</sup>](#) when the user selects it, then the UA must invoke that command's [Action<sup>p580</sup>](#). If the command's [Action<sup>p580</sup>](#) is defined as [firing a click event<sup>p846</sup>](#), either directly or via the [run synthetic click activation steps<sup>p724</sup>](#) algorithm, then the [relatedTarget<sup>p51</sup>](#) attribute of that [click<sup>p52</sup>](#) event must be initialised to **subject**.

Pop-up menus must not, while being shown, reflect changes in the DOM. The menu is constructed from the DOM before being shown, and is then immutable.

To **build a menu construct** for an element **source**, the user agent must run the following steps, which return a [menu construct<sup>p572</sup>](#):

1. Let **generated menu** be an empty [menu construct<sup>p572</sup>](#).
2. Run the [menu item generator<sup>p572</sup>](#) steps for the [menu<sup>p571</sup>](#) element using **generated menu** as the output.

The **menu item generator** steps for a [menu<sup>p571</sup>](#) element using a specific [menu construct<sup>p572</sup>](#) **output** as output are as follows: For each child node of the [menu<sup>p571</sup>](#) in [tree order<sup>p42</sup>](#), run the appropriate steps from the following list:

↪ **If the child is a [menuitem<sup>p574</sup>](#) element that defines a command<sup>p579</sup>**

Append the [command<sup>p579</sup>](#) to **output**, respecting the command's [facets<sup>p579</sup>](#). If the [menuitem<sup>p574</sup>](#) element has a [default command<sup>p572</sup>](#) attribute, mark the command as being a [default command<sup>p572</sup>](#).

↪ **If the child is an [hr<sup>p190</sup>](#) element**

Append a [separator<sup>p572</sup>](#) to **output**.

↪ If the child is a [menu<sup>p571</sup>](#) element with no [label<sup>p572</sup>](#) attribute

Append a [separator<sup>p572</sup>](#) to [output](#), then run the [menu item generator<sup>p572</sup>](#) steps for this child [menu<sup>p571</sup>](#) element, using [output](#) as the output, then append another [separator<sup>p572</sup>](#) to [output](#).

↪ If the child is a [menu<sup>p571</sup>](#) element with a [label<sup>p572</sup>](#) attribute

Let [submenu](#) be the result of running the [build a menu construct<sup>p572</sup>](#) steps for the child [menu<sup>p571</sup>](#) element. Then, append [submenu](#) to [output](#), using the value of the child [menu<sup>p571</sup>](#) element's [label<sup>p572</sup>](#) attribute as the [submenu label<sup>p572</sup>](#).

↪ Otherwise

[Ignore<sup>p42</sup>](#) the child node.

3. Remove from [output](#) any [menu construct<sup>p572</sup>](#) whose [submenu label<sup>p572</sup>](#) is the empty string.
4. Remove from [output](#) any [menu item construct<sup>p572</sup>](#) representing a [command<sup>p579</sup>](#) whose [Label<sup>p580</sup>](#) is the empty string.
5. Collapse all sequences of two or more adjacent [separators<sup>p572</sup>](#) in [output](#) to a single [separator<sup>p572</sup>](#).
6. If the first [menu item construct<sup>p572</sup>](#) in [output](#) is a [separator<sup>p572</sup>](#), then remove it.
7. If the last [menu item construct<sup>p572</sup>](#) in [output](#) is a [separator<sup>p572</sup>](#), then remove it.
8. Return [output](#).

The [type](#) IDL attribute must [reflect<sup>p88</sup>](#) the content attribute of the same name, [limited to only known values<sup>p89</sup>](#).

The [label](#) IDL attribute must [reflect<sup>p88</sup>](#) the content attribute of the same name.

**Example**

In this example, the [menu<sup>p571</sup>](#) element is used to describe a toolbar with three menu buttons on it, each of which has a dropdown menu with a series of options:

```
<menu>

 <button type=menu value="File" menu="filemenu">
 <menu id="filemenu" type="popup">
 <menuitem onclick="fnew()" label="New...">
 <menuitem onclick="fopen()" label="Open...">
 <menuitem onclick="fsave()" label="Save">
 <menuitem onclick="fsaveas()" label="Save as...">
 </menu>

 <button type=menu value="Edit" menu="editmenu">
 <menu id="editmenu" type="popup">
 <menuitem onclick="ecopy()" label="Copy">
 <menuitem onclick="ecut()" label="Cut">
 <menuitem onclick="epaste()" label="Paste">
 </menu>

 <button type=menu value="Help" menu="helpmenu">
 <menu id="helpmenu" type="popup">
 <menuitem onclick="location='help.html'" label="Help">
 <menuitem onclick="location='about.html'" label="About">
 </menu>

 </menu>
```

In a supporting user agent, this might look like this (assuming the user has just activated the second button):

#### 4.11.4 The `menuitem` element

Categories<sup>p113</sup>:

None.

Contexts in which this element can be used<sup>p113</sup>:

As a child of a `menu`<sup>p571</sup> element whose `type`<sup>p572</sup> attribute is in the `popup menu`<sup>p572</sup> state.

Content model<sup>p113</sup>:

Nothing<sup>p114</sup>.

Tag omission in text/html<sup>p113</sup>:

No end tag<sup>p944</sup>.

Content attributes<sup>p113</sup>:

Global attributes<sup>p120</sup>

type<sup>p575</sup> — Type of command

label<sup>p575</sup> — User-visible label

icon<sup>p575</sup> — Icon for the command

disabled<sup>p575</sup> — Whether the form control is disabled

checked<sup>p575</sup> — Whether the command or control is checked

radiogroup<sup>p575</sup> — Name of group of commands to treat as a radio button group

default<sup>p575</sup> — Mark the command as being a default command

command<sup>p575</sup> — Command definition

Also, the title<sup>p575</sup> attribute has special semantics<sup>p575</sup> on this element: Hint describing the command.

DOM interface<sup>p113</sup>:

```
IDL
interface HTMLMenuItemElement : HTMLElement {
 attribute DOMString type;
 attribute DOMString label;
 attribute DOMString icon;
 attribute boolean disabled;
 attribute boolean checked;
 attribute DOMString radiogroup;
 attribute boolean default;
 readonly attribute HTMLElement? command;
};
```

The `menuitem`<sup>p574</sup> element represents a command that the user can invoke from a popup menu (either a `context menu`<sup>p577</sup> or the menu of a `menu button`<sup>p497</sup>).

A `menuitem`<sup>p574</sup> element that uses one or more of the `type`<sup>p575</sup>, `label`<sup>p575</sup>, `icon`<sup>p575</sup>, `disabled`<sup>p575</sup>, `checked`<sup>p575</sup>, and `radiogroup`<sup>p575</sup> attributes defines a new command.

A `menuitem`<sup>p574</sup> element that uses the `command`<sup>p575</sup> attribute defines a command by reference to another one. This allows authors to define a command once, and set its state (e.g. whether it is active or disabled) in one place, and have all references to that command in the user interface change at the same time.

If the `command`<sup>p575</sup> attribute is specified, the element is in the **indirect command** mode. If it is not specified, it is in the **explicit command** mode. When the element is in the **indirect command**<sup>p575</sup> mode, the element must not have any of the following attributes specified: `type`<sup>p575</sup>, `label`<sup>p575</sup>, `icon`<sup>p575</sup>, `disabled`<sup>p575</sup>, `checked`<sup>p575</sup>, `radiogroup`<sup>p575</sup>.

The `type` attribute indicates the kind of command: either a normal command with an associated action, or a state or option that can be toggled, or a selection of one item from a list of items.

The attribute is an [enumerated attribute](#)<sup>p60</sup> with three keywords and states. The "command" keyword maps to the [Command](#)<sup>p575</sup> state, the "checkbox" keyword maps to the [Checkbox](#)<sup>p575</sup> state, and the "radio" keyword maps to the [Radio](#)<sup>p575</sup> state. The [missing value default](#)<sup>p60</sup> is the [Command](#)<sup>p575</sup> state.

#### The **Command** state

The element [represents](#)<sup>p111</sup> a normal command with an associated action.

#### The **Checkbox** state

The element [represents](#)<sup>p111</sup> a state or option that can be toggled.

#### The **Radio** state

The element [represents](#)<sup>p111</sup> a selection of one item from a list of items.

The `label` attribute gives the name of the command, as shown to the user. The `label`<sup>p575</sup> attribute must be specified if the element is in the [explicit command](#)<sup>p575</sup> mode. If the attribute is specified, it must have a value that is not the empty string.

The `icon` attribute gives a picture that represents the command. If the attribute is specified, the attribute's value must contain a [valid non-empty URL potentially surrounded by spaces](#)<sup>p82</sup>. To obtain the [absolute URL](#)<sup>p48</sup> of the icon when the attribute's value is not the empty string, the attribute's value must be [resolved](#)<sup>p82</sup> relative to the element. When the attribute is absent, or its value is the empty string, or [resolving](#)<sup>p82</sup> its value fails, there is no icon.

The `disabled` attribute is a [boolean attribute](#)<sup>p59</sup> that, if present, indicates that the command is not available in the current state.

**Note** *The distinction between `disabled`<sup>p575</sup> and `hidden`<sup>p723</sup> is subtle. A command would be disabled if, in the same context, it could be enabled if only certain aspects of the situation were changed. A command would be marked as hidden if, in that situation, the command will never be enabled. For example, in the context menu for a water faucet, the command "open" might be disabled if the faucet is already open, but the command "eat" would be marked hidden since the faucet could never be eaten.*

The `checked` attribute is a [boolean attribute](#)<sup>p59</sup> that, if present, indicates that the command is selected. The attribute must be omitted unless the `type`<sup>p575</sup> attribute is in either the [Checkbox](#)<sup>p575</sup> state or the [Radio](#)<sup>p575</sup> state.

The `radiogroup` attribute gives the name of the group of commands that will be toggled when the command itself is toggled, for commands whose `type`<sup>p575</sup> attribute has the value "radio". The scope of the name is the child list of the parent element. The attribute must be omitted unless the `type`<sup>p575</sup> attribute is in the [Radio](#)<sup>p575</sup> state. When specified, the attribute's value must be a non-empty string.

If a [menuitem](#)<sup>p574</sup> element *slave* has a `command` attribute, and there is an element in *slave*'s [home subtree](#)<sup>p42</sup> whose `ID`<sup>p51</sup> has a value equal to the value of *slave*'s `command`<sup>p575</sup> attribute, and the first such element in [tree order](#)<sup>p42</sup>, hereafter *master*, itself [defines a command](#)<sup>p579</sup> and either is not a [menuitem](#)<sup>p574</sup> element or does not itself have a `command`<sup>p575</sup> attribute, then the **master command** of *slave* is *master*.

A [menuitem](#)<sup>p574</sup> element with a `command`<sup>p575</sup> attribute must have a [master command](#)<sup>p575</sup>.

**Note** *This effectively defines the syntax of the attribute's value as being the ID of another element that defines a command*<sup>p579</sup>.

The `title` attribute gives a hint describing the command, which might be shown to the user to help him.

The `default` attribute indicates, if present, that the command is the one that would have been invoked if the user had directly activated the menu's subject instead of using the menu. The `default`<sup>p575</sup> attribute is a [boolean attribute](#)<sup>p59</sup>.

#### Example

In this trivial example, a submit button is given a context menu that has two options, one to reset the form, and one to submit the form. The submit command is marked as being the default.

```
<form action="dosearch.pl">
<p><label>Enter search terms: <input type="text" name="terms"></label></p>
<p><input type=submit contextmenu=formmenu id="submitbutton"></p>
<p hidden><input type=reset id="resetbutton"></p>
<menu type=popup id=formmenu>
<menuitem command="submitbutton" default>
<menuitem command="resetbutton">
</menu>
</form>
```

The `type` IDL attribute must [reflect<sup>b88</sup>](#) the content attribute of the same name, [limited to only known values<sup>b89</sup>](#).

The `label`, `icon`, `disabled`, `checked`, and `radiogroup`, and `default` IDL attributes must [reflect<sup>b88</sup>](#) the respective content attributes of the same name.

The `command` IDL attribute must return the [master command<sup>b575</sup>](#), if any, or null otherwise.

If the element's [Disabled State<sup>b580</sup>](#) is false (enabled) then the element's [activation behaviour<sup>b725</sup>](#) depends on the element's `typeb575` and `commandb575` attributes, as follows:

↪ If the element has a [master command<sup>b575</sup>](#) set by its `commandb575` attribute

The user agent must [run synthetic click activation steps<sup>b724</sup>](#) on the element's [master command<sup>b575</sup>](#).

↪ If the `typeb575` attribute is in the [Checkbox<sup>b575</sup>](#) state

If the element has a [checked<sup>b575</sup>](#) attribute, the UA must remove that attribute. Otherwise, the UA must add a [checked<sup>b575</sup>](#) attribute, with the literal value "checked".

↪ If the `typeb575` attribute is in the [Radio<sup>b575</sup>](#) state

If the element has a parent, then the UA must walk the list of child nodes of that parent element, and for each node that is a [menuitem<sup>b574</sup>](#) element, if that element has a [radiogroup<sup>b575</sup>](#) attribute whose value exactly matches the current element's (treating missing [radiogroup<sup>b575</sup>](#) attributes as if they were the empty string), and has a [checked<sup>b575</sup>](#) attribute, must remove that attribute.

Then, the element's [checked<sup>b575</sup>](#) attribute must be set to the literal value "checked".

↪ Otherwise

The element's [activation behaviour<sup>b725</sup>](#) is to do nothing.

**Note** Firing a synthetic [click<sup>b52</sup>](#) event at the element does not cause any of the actions described above to happen.

If the element's [Disabled State<sup>b580</sup>](#) is true (disabled) then the element has no [activation behaviour<sup>b725</sup>](#).

**Note** The [menuitem<sup>b574</sup>](#) element is not rendered except as part of a popup menu<sup>b571</sup>.

**Example**

Here is an example of a pop-up menu button with three options that let the user toggle between left, center, and right alignment. One could imagine such a toolbar as part of a text editor. The menu also has a separator followed by another menu item labeled "Publish", though that menu item is disabled.

```
<button type=menu menu=editmenu>Commands...</button>
<menu type="popup" id="editmenu">
<menuitem type="radio" radiogroup="alignment" checked="checked"
 label="Left" icon="icons/all.png" onclick="setAlign('left')">
<menuitem type="radio" radiogroup="alignment"
 label="Center" icon="icons/alc.png" onclick="setAlign('center')">
<menuitem type="radio" radiogroup="alignment"
